Global fixed points for centralizers and Morita’s Theorem

John Franks∗, Michael Handel†

February 2, 2008

Abstract

We prove a global fixed point theorem for the centralizer of a homeomorphism of the two dimensional disk $D$ that has attractor-repeller dynamics on the boundary with at least two attractors and two repellers. As one application, we show that there is a finite index subgroup of the centralizer of a pseudo-Anosov homeomorphism with infinitely many global fixed points. As another application we give an elementary proof of Morita’s Theorem, that the mapping class group of a closed surface $S$ of genus $g$ does not lift to the group of diffeomorphisms of $S$ and we improve the lower bound for $g$ from 5 to 3.

1 Introduction

In this article we are concerned with the properties of groups of homeomorphisms or diffeomorphisms of surfaces. We assume throughout that $S$ is a surface of finite negative Euler characteristic, without boundary but perhaps with punctures. We denote the group of orientation preserving homeomorphisms of $S$ and the group of orientation preserving $C^1$ diffeomorphisms of $S$ by $\text{Homeo}(S)$ and $\text{Diff}(S)$ respectively and we denote the subgroups consisting of elements that are isotopic to the identity by $\text{Homeo}_0(S)$ and $\text{Diff}_0(S)$ respectively.

An important tool in the study of subgroups of these groups is the existence of a global fixed point. A global fixed point for a subgroup $\mathcal{G}$ of $\text{Homeo}(S)$ is a point $x \in S$ that is fixed by each element of $\mathcal{G}$. The set of global fixed points for $\mathcal{G}$ is denoted $\text{Fix}(\mathcal{G})$. When $G$ is a subgroup of $\text{Diff}(S)$ and $\text{Fix}(\mathcal{G})$ is non-empty, the assignment $g \mapsto Dg_x$ (the derivative of $g$ at $x \in \text{Fix}(\mathcal{G})$), gives a representation of $\mathcal{G}$ in $Gl(2, \mathbb{R})$. This representation can be very useful for understanding $\mathcal{G}$; for example in [FH] this representation was used to prove that many lattices, including $SL(3, \mathbb{Z})$,
are not isomorphic to a subgroup of the group of measure preserving diffeomorphisms of a surface.

Unfortunately, there are no general techniques for finding a global fixed point for a subgroup of Homeo(S). In particular there are no analogues of the standard tools of algebraic topology for finding fixed points of a single map. In the case of surfaces there is a literature concerning the existence of global fixed points, but it is largely limited to abelian groups (see, e.g. [B1], [B2], [H], [FHP], and [FHP2]).

The main objective of this article is to provide a technique which, in many cases, allows us to find a global fixed point for the centralizer of \( f \in \text{Homeo}(S) \). We denote the centralizer of \( f \) by \( \text{Cent}(f) \) and observe that it can be a very large group and, in particular, is generally far from abelian.

As one application of this result we address the “lifting problem” for the mapping class group (see §6 of [Fa]). Using our result on global fixed points and the representation in \( \text{Gl}(2, \mathbb{R}) \) mentioned above, we give an elementary proof of an important theorem of Morita about the non-existence of liftings of the full mapping class group to \( \text{Diff}(S) \) and improve the lower bound on the genus of \( S \) required for the result (see Theorem 1.5 below).

The closed two dimensional disk is denoted \( D \). The universal cover \( \tilde{S} \) of \( S \) is naturally identified with \( \text{int} D \) and the compactification of \( \tilde{S} \) by the circle at infinity \( S_\infty \) is naturally identified with \( D \). For this reason, our main result concerns global fixed points for group actions on \( D \).

**Theorem 1.1.** Let \( \mathcal{G} \) be a subgroup of \( \text{Homeo}(D) \) and let \( f \) be an element of the center of \( \mathcal{G} \). Suppose \( K := \text{Fix}(f) \cap \partial D \) consists of a finite set with more than two elements each of which is either an attracting or repelling fixed point for \( f : D \to D \). Let \( \mathcal{G}_0 \subset \mathcal{G} \) denote the finite index subgroup whose elements pointwise fix \( K \). Then \( \text{Fix}(\mathcal{G}_0) \cap \text{int}(D) \) is non-empty.

The hypothesis of this theorem has both an algebraic part, namely that \( \mathcal{G}_0 \subset \text{Cent}(f) \), and a dynamical part, namely that \( f|_{\partial D} \) has attractor-repeller dynamics. The latter implies that \( \text{Fix}(f) \cap \text{int} D \neq \emptyset \). The former is used to relate the dynamics of elements of \( \mathcal{G}_0 \) to \( f \) and hence to each other.

The fixed point set \( \text{Fix}(f) \) of \( f \in \text{Homeo}(S) \) is partitioned into Nielsen classes. Two elements \( x, y \in \text{Fix}(f) \) belong to the same Nielsen class if there is a lift \( \tilde{f} : \tilde{S} \to \tilde{S} \) of \( f : S \to S \) and lifts \( \tilde{x}, \tilde{y} \in \text{Fix}(\tilde{f}) \) of \( x \) and \( y \). Equivalently, every lift of \( f \) that fixes a lift of \( x \) also fixes a lift of \( y \). If \( f \) is isotopic to \( g \) and \( \tilde{f} \) is a lift of \( f \) then the isotopy between \( f \) and \( g \) lifts to an isotopy between \( \tilde{f} \) and a lift \( \tilde{g} \) of \( g \). We say that \( \tilde{f} \) and \( \tilde{g} \) are paired. Pairing defines a bijection between lifts of \( f \) and lifts of \( g \) and we say that the \( f \)-Nielsen class of \( x \in \text{Fix}(f) \) is paired with the \( g \)-Nielsen class of \( z \in \text{Fix}(g) \) if there are paired lifts \( \tilde{f} \) and \( \tilde{g} \) of \( f \) and \( g \) and there are lifts \( \tilde{x} \in \text{Fix}(\tilde{f}) \) of \( x \) and \( \tilde{z} \in \text{Fix}(\tilde{g}) \) of \( z \).

By a pseudo-Anosov homeomorphism of a punctured surface we mean the restriction of a homeomorphism of the unpunctured surface that is pseudo-Anosov relative
to the set of punctures.

**Theorem 1.2.** Suppose that \( \alpha \in \text{Homeo}(S) \) is pseudo-Anosov and that \( f \in \text{Homeo}(S) \) is isotopic to \( \alpha \). Let \( \mathcal{H}_0 = \text{Cent}(f) \cap \text{Homeo}_0(S) \). Then \( \text{Fix}(\mathcal{H}_0) \) is infinite. More precisely, for each \( n \geq 0 \) and each \( y \in \text{Fix}(\alpha^n) \) there exists \( x \in \text{Fix}(\mathcal{H}_0) \cap \text{Fix}(f^n) \) such that the Nielsen class of \( f^n \) determined by \( x \) is paired with the Nielsen class of \( \alpha^n \) determined by \( y \).

In the special case that \( f = \alpha \), the group \( \mathcal{H}_0 \) is trivial (see, e.g. [FLP]) and Theorem 1.2 is an immediate consequence of the fact that \( \alpha \) has the fewest possible periodic points in its isotopy class. Thus Theorem 1.2 fits into the general scheme of results in surface dynamics in which an important property of pseudo-Anosov maps is extended to all elements of its isotopy class.

**Remark 1.3.** Suppose that \( f' : T^2 \to T^2 \) is isotopic to a linear Anosov homeomorphism \( \alpha' : T^2 \to T^2 \) and that \( e \in \text{Fix}(\alpha) \) is the image of \((0,0) \in \mathbb{R}^2 \) under the usual covering map. Let \( S = T^2 \setminus \{e\} \), let \( f = f'|_S \) and let \( \alpha = \alpha'|_S \). Then \( \alpha \) is pseudo-Anosov and we may apply Theorem 1.2. The conclusions are exactly as given in the theorem but are applied to the subgroup \( \mathcal{H}'_0 \) of \( \text{Cent}(f') \) that are isotopic the identity relative to \( e \).

Our next result is the analogue of Theorem 1.2 for reducible isotopy classes with a pseudo-Anosov component. It is a corollary of, and the original motivation for, Theorem 1.1 since it provides the tool we use to prove Morita’s theorem.

**Theorem 1.4.** Suppose that \( f \in \text{Homeo}(S) \), that \( S_0 \subset S \) is an incompressible subsurface and that \( f \) is isotopic to \( \alpha \in \text{Homeo}(S) \) where \( \alpha(S_0) = S_0 \) and \( \alpha|_{S_0} \) is pseudo-Anosov. Let \( \mathcal{H}_0 \) be the subgroup of \( \text{Cent}(f) \) consisting of elements that are isotopic to a homeomorphism that pointwise fixes \( S_0 \). Then \( \text{Fix}(\mathcal{H}_0) \) is infinite. More precisely, for each \( n \geq 0 \) and each \( y \in \text{Fix}(\alpha^n) \cap S_0 \) there exists \( x \in \text{Fix}(\mathcal{H}_0) \cap \text{Fix}(f^n) \cap S \) such that the Nielsen class of \( f^n \) determined by \( x \) is paired with the Nielsen class of \( \alpha^n \) determined by \( y \).

The mapping class group \( \text{MCG}(S) \) of a closed surface \( S \) is the group of isotopy classes of orientation preserving homeomorphisms of \( S \). There is a natural homomorphism \( \text{Homeo}(S) \to \text{MCG}(S) \) that sends \( h \in \text{Homeo}(S) \) to its isotopy class \([h] \in \text{MCG}(S)\). A lift of a subgroup \( \Gamma \) of \( \text{MCG}(S) \) is a homomorphism \( \Gamma \to \text{Homeo}(S) \) so that the composition

\[
\Gamma \to \text{Homeo}(S) \to \text{MCG}(S)
\]
is the inclusion. Every free abelian subgroup (see §6.3 of [Fa]) and every finite subgroup \([\text{Ker}] \) of \( \text{MCG}(S) \) has a lift to \( \text{Diff}(S) \). Morita [Mor1], [Mor2] proved that \( \text{MCG}(S) \) does not lift to \( \text{Diff}(S) \) for genus(\( S \)) \( \geq 5 \) and Markovich [Mark] proved that \( \text{MCG}(S) \) does not lift to \( \text{Homeo}(S) \) for genus(\( S \)) \( \geq 6 \).

Using Theorem 1.4 and the Thurston stability theorem we give an elementary proof of Morita’s theorem and improve the lower bound on the genus.
Theorem 1.5. MCG(S) does not lift to Diff(S) for genus(S) ≥ 3.

This is actually a special case of a more general result in which we consider homomorphisms \( \mathcal{L} : \Gamma \to \text{Diff}(S) \) that are not necessarily lifts.

Suppose that \( S = S_1 \cup S_2 \) where \( S_1 \) and \( S_2 \) are incompressible subsurfaces with disjoint interiors. Recall that the relative mapping class group MCG\((S_i, \partial S_i)\) is the set of isotopy classes rel \( \partial S_i \) of homeomorphisms \( h : S_i \to S_i \) that are the identity on \( \partial S_i \). Each such \( h \) extends by the identity to a homeomorphism \( S \). This induces a homomorphism \( \Phi : \text{MCG}(S_i, \partial S_i) \to \text{MCG}(S) \). If \( S \) is given a hyperbolic structure with \( \partial S_i \) a union of geodesics, it is straightforward to see that any \( f \in \text{Homeo}_0(S) \) is actually homotopic to the identity along geodesics, i.e. with \( f_t(x) \) on the geodesic from \( x \) to \( f(x) \) determined by the isotopy. From this it follows that if \( f \) is the identity on the complement of \( S_i \), then we may choose a homotopy from \( f \) to the identity with the same property, and hence an isotopy of \( f|_{S_i} \) to the identity rel \( \partial S_i \). Therefore the homomorphism \( \Phi \) is injective and we use it to identify MCG\((S_i, \partial S_i)\) with a subgroup of MCG\((S)\).

**Theorem 1.6.** Assume notation as above and that \( \Gamma = \langle \Gamma_1, \mu \rangle \) where

- \( \Gamma_1 \) is a non-trivial finitely generated subgroup of MCG\((S_1, \partial S_1)\) such that \( H^1(\Gamma_1) \) has rank zero.
- \( \mu \in \text{MCG}(S_2, \partial S_2) \).

Then there does not exist a faithful homomorphism \( \mathcal{L} : \Gamma \to \text{Diff}(S) \) such that

1. \( [\mathcal{L}(\Gamma_1)] \subset \text{MCG}(S_1, \partial S_1)) \).
2. \( [\mathcal{L}(\mu)] \in \text{MCG}(S_2, \partial S) \) is represented by \( \alpha : S \to S \) where \( \alpha(S_2) = S_2 \) and \( \alpha|_{S_2} \) is pseudo-Anosov.

Theorem 1.5 follows from Theorem 1.6 and the fact \( \text{Ko} \) that \( H^1(\text{MCG}(S_1, \partial S_1)) \) has rank zero. It is conjectured that \( H(\Gamma) \) has rank zero for all finite index subgroups \( \Gamma \) of MCG\((S)\). If that conjecture is verified then Theorem 1.6 will imply that no finite index subgroup of MCG\((S)\) lifts to Diff\((S)\), which is known for genus at least 5 because Morita’s original proof applies to all finite index subgroups of MCG\((S)\).

We thank Benson Farb for several very helpful conversations.

## 2 A Global Fixed Point Theorem

We begin with generalities about attracting fixed points.

Suppose that \( f : X \to X \) is a homeomorphism of a locally compact metric space \( X \) and that \( x_0 \in \text{Fix}(h) \). We say that \( x_0 \) is an attracting fixed point for \( f \) if there is a compact neighborhood \( W \) of \( x_0 \) such that the \( f^n(W) \to \{x_0\} \) in the Hausdorff
topology; i.e. for every neighborhood $N$ of $x_0$, we have $f^n(W) \subset N$ for all sufficiently large $n$. The \textit{basin of attraction of $x_0$ with respect to $f$} is defined to be \{ $x \in X : \lim_{n \to \infty} f^n(x) = x_0$ \}. Note that the basin of attraction of $x_0$ is $f$-invariant and contains $W$.

\begin{remark} \label{rem:2.1} \textbf{Remark 2.1.} \textbf{If $W$ is a compact neighborhood of $x_0$ such that $f(W) \subset W$ then $f^n(W) \to \{x_0\}$ in the Hausdorff topology if and only if $\cap_{n=1}^{\infty} f^n(W) = \{x_0\}$. Thus by item (3) of Lemma 2.2 below, $x_0$ is an attracting fixed point if and only if it has a compact neighborhood $W$ such that $f(W) \subset W$ and $\cap_{n=1}^{\infty} f^n(W) = \{x_0\}$.} \end{remark}

If $x$ is an attracting fixed point for $f^{-1}$ then it is a \textit{repelling} fixed point for $f$.

\begin{lemma} \label{lem:2.2} \textbf{Lemma 2.2.} \textbf{Let $f : X \to X$ be a homeomorphism of a locally compact metric space with an attracting fixed point $x_0 \in X$ and basin of attraction $U$.} \end{lemma}

\begin{enumerate}
\item For any compact neighborhood $W_0 \subset U$ of $x_0$,
\begin{equation*}
\bigcup_{i=0}^{\infty} f^{-i}(W_0) = \bigcup_{i=0}^{\infty} f^{-i}(\text{int } W_0) = U.
\end{equation*}
\item For any compact set $A \subset U$, $\lim_{n \to \infty} f^n(A) = \{x_0\}$ in the Hausdorff topology.
\item There exists arbitrarily small compact neighborhoods $V$ of $x$ such that $f(V) \subset V$.
\item If $x_0$ is also an attracting fixed point for a homeomorphism $g : X \to X$ that commutes with $f$ then $U$ is the basin of attraction of $x$ with respect to $g$.
\end{enumerate}

\begin{proof} \textbf{Proof.} Let $W$ be a compact neighborhood of $x_0$ as in the definition of attracting fixed point.

Suppose that $W_0 \subset U$ is a compact neighborhood of $x_0$. Since $U$ is $f^{-1}$-invariant, $\bigcup_{i=0}^{\infty} f^{-i}(W_0) \subset U$. Conversely, if $x \in U$ then $f^i(x) \in \text{int } W_0$ for all sufficiently large $i$. This proves that $U \subset \bigcup_{i=0}^{\infty} f^{-i}(\text{int } W_0) \subset \bigcup_{i=0}^{\infty} f^{-i}(W_0) \subset U$ which proves (1).

For (2), suppose that $A$ is a compact subset of $U$ and that $N$ is a compact neighborhood of $x$. Then $U = \bigcup_{i=0}^{\infty} f^{-i}(\text{int } N)$ by (1) and hence $A \subset f^{-m}(\text{int } N)$ for some $m > 0$. Thus $f^i(A) \subset (N)$ for all $i \geq m$ and we conclude $\lim_{n \to \infty} f^n(A) \subset \bigcap_{i=0}^{\infty} f^i(W)$. This proves (2).

For (3), choose $q > 0$ such that $f^q(W) \subset \text{int}(W)$ and define $V_1 = \bigcup_{k=0}^{q} f^k(W) \subset U$. Then $f(V_1) \subset V_1$. Given a neighborhood $N$ of $x$ choose $l \geq 0$ so that $f^l(V_1) \subset N$ and let $V = f^l(V_1)$. Then $V \subset N$ and $f(V) \subset V$.

Suppose now that $g$ is as in (4) and that $U'$ is the basin of attraction of $x_0$ with respect to $g$. For any compact neighborhood $N \subset U \cap U'$ of $x_0$, $U = \bigcup_{i=0}^{\infty} f^{-i}(\text{int } N)$ and $U' = \bigcup_{j=0}^{\infty} g^{-j}(\text{int } N)$ by (1). For all $i \geq 0$ there exists $j \geq 0$ so that $g^j(N) \subset f^i(\text{int } N)$. Thus $g^j(f^{-i}(N)) = f^{-i}(g^j(N)) \subset \text{int } N$ or equivalently $f^{-i}(N) \subset g^{-j}(\text{int } N)$. This proves that $U \subset U'$. The reverse inclusion follows by symmetry. \end{proof}
Lemma 2.3. Let $f : X \to X$ be a homeomorphism of a locally compact metric space and let $x_0 \in X$ be an attracting fixed point for $f$. If $g : X \to X$ is a homeomorphism that commutes with $f$ and fixes $x_0$ then there exists $m > 0$ such that $x_0$ is an attracting fixed point for $h = f^m g$.

Proof. Let $U$ be the basin of attraction for $x_0$ with respect to $f$. Then $g(U)$ is the basin of attraction for $x_0$ with respect to $gf^{-1} = f$ which implies that $g(U) = U$. By part (3) of Lemma 2.2 there is a compact neighborhood $V$ of $x_0$ such that $f(V) \subset V$. By part (2) of the same lemma there is $m > 0$ such that $f^m(g(V)) \subset f(V)$.

Define $h = f^m g$. Thus $h(V) \subset f(V) \subset V$. Applying $h^{n-1}$ we conclude $h^n(V) \subset fh^{n-1}(V)$ for all $n$. Hence

$$f^{-1}h^n(V) \subset h^{n-1}(V)$$

for all $n$.

Let $\Lambda$ be the non-empty compact set $\cap_{n \geq 0} h^n(V)$. Then $f(\Lambda) \subset \Lambda$ because $f(V) \subset V$. Also, the displayed inclusion above implies $f^{-1}(\Lambda) \subset \Lambda$. We conclude that $f(\Lambda) = \Lambda$ so by part (2) of Lemma 2.2 the only possibility is that $\Lambda = \{x_0\}$. By Remark 2.1 this proves that $x_0$ is an attracting fixed point for $h$. \qed

We now turn to the proof of our main result.

Proof of Theorem 1.1. The points of $K$ are attractors or repellers for $f$ and hence a fortiori attractors or repellers for $f|_{\partial D}$. Hence there must be an equal number of attractors and repellers which alternate on $\partial D$. We will denote the attractors $\{p_1, \ldots, p_k\}$ and the repellers $\{q_1, \ldots, q_k\}$ in their circular order.

For simplicity it is useful to consider the two sphere $S^2$ obtained by doubling $D$ along its boundary. There is a natural extension of $f$ to $S^2$ which we will also denote by $f$. Then $\{p_1, \ldots, p_k\}$ are attracting fixed points of $f : S^2 \to S^2$ and $\{q_1, \ldots, q_k\}$ are repelling fixed points. Each element of $\mathcal{G}_0$ also extends in a natural way to $S^2$ and abusing notation we will denote this group by $\mathcal{G}_0$.

Let $\mathcal{H}$ be the set of elements of $(\mathcal{G}_0, f)$ for which each $p_i$ is an attractor and each $q_i$ is a repeller. Then $f \in \mathcal{H}$ and by Lemma 2.3 for all $g \in \mathcal{G}_0$ there exists $m > 0$ such that $f^m g \in \mathcal{H}$. Our goal is to find $y \in S^2$, not in the set $\{p_1, \ldots, p_k\} \cup \{q_1, \ldots, q_k\}$, such that $y \in \text{Fix}(h)$ for each $h \in \mathcal{H}$. We then observe that $y \in \text{Fix}(f) \cap \text{Fix}(f^m g) \subset \text{Fix}(g)$ for all $g \in \mathcal{G}_0$ which will complete the proof.

Remark 2.4. An easy index argument shows that for each $h \in \mathcal{H}$ there is at least one element of $\text{Fix}(h)$ that has negative index and so is neither a source nor a sink. The challenge here is to find a single point that works for all $h$. The point we find in $\text{Fix}(\mathcal{H})$ will be shown to be neither a source nor a sink for any element $h \in \mathcal{H}$, but we do not know about its index.

Lemma 2.2 (4) and the fact that each $h \in \mathcal{H}$ commutes with $f$ imply that the basin of attraction $U$ for $p_1$ with respect to $h \in \mathcal{H}$ is independent of $h$. By Lemma 2.2 (1), $U$ can be written as an increasing union of open disks and so is connected and
simply connected. The fact that there is another attractor \( p_2 \) implies that the frontier of \( U \) is not a single point.

We will be interested in two compactifications of \( U \). The first is \( \bar{U} \), the closure of \( U \) in \( S^2 \) and the second is \( \hat{U} \), the prime end compactification. The set \( \Gamma = \bar{U} \setminus U \) of prime ends is topologically a circle. Each homeomorphism \( h \mid_U : U \to U \) extends to homeomorphism \( \hat{h} : \hat{U} \to \hat{U} \). Moreover,

\[ \forall \text{ each continuous arc } \gamma : [0, 1] \to \bar{U} \text{ with } \gamma([0, 1]) \subset U \text{ and } \gamma(1) \text{ in the frontier of } U \text{ there is a continuous arc } \hat{\gamma} : [0, 1] \to \hat{U} \text{ with } \hat{\gamma}(t) = \gamma(t) \text{ for } t \in [0, 1]. \]

The point \( \gamma(1) \) is called an accessible point of the frontier of \( U \) and \( \hat{\gamma}(1) \) is a prime end corresponding to it (there may be more than one prime end corresponding to an accessible point).

These properties go back to Caratheodory. An excellent modern exposition can be found in Mather's paper \([M]\). In particular see §17 of \([M]\) for a discussion of accessible points.

Let \( C \) denote the arc in \( \partial D \) joining \( p_1 \) and \( q_1 \) and not containing any other points of \( \text{Fix}(h) \). Then \( C \subset \bar{U} \) and all but the endpoint \( q_1 \) of \( C \) lies in \( U \). By (\*), the half open arc \( C \cap U \) converges to a prime end \( \hat{w} \in \Gamma \) that is fixed by each \( \hat{h} \) since \( C \) is \( h \)-invariant for each \( h \).

Our first objective is to show that \( \hat{w} \) is a repelling fixed point for each \( \hat{h} \) or equivalently an attracting fixed point for each \( \hat{h}^{-1} \). For this, there is no loss in replacing \( h \) by an iterate so by applying Lemma 2.2-(2) we may choose a disk neighborhood \( D_1 \) of \( q_1 \) in the basin of attraction of \( q_1 \) with respect to \( h^{-1} \) such that \( h^{-1}(D_1) \subset \text{int}(D_1) \).

Let \( \gamma_0 \) denote the component of \( \partial D_1 \cap U \) which intersects \( C \), and let \( \gamma_i = h^{-i}(\gamma_0) \). Note that each \( \gamma_i \) intersects \( C \) and is the interior of a closed path \( \hat{\gamma}_i \subset \hat{U} \) and so by (\*) is the interior of a closed path \( \tilde{\gamma}_i \subset \hat{U} \). The \( \gamma_i \)'s separate \( U \) into two complementary components \( V_i \) and \( W_i \) with \( W_{i+1} \subset W_i \) and \( \cap_{i=1}^{\infty} W_i = \emptyset \) (where the last property follows from Remark 2.1). By Corollary 4 of \([M]\), the \( \tilde{\gamma}_i \)'s converge to a single prime end, which must be \( \hat{w} \) since each \( \hat{\gamma}_i \) intersects \( C \). The \( h^{-1} \)-orbit of the endpoints of \( \tilde{\gamma}_i \) converge to \( \hat{w} \). This proves that \( \hat{w} \) is an attractor for \( h^{-1} \).

The next step is to find a prime end \( \hat{y} \) that is fixed by each \( \hat{h} \) and that does not come from \( \partial D \). Since each \( \hat{h} \) commutes with \( \hat{f} \), Lemma 2.2-(4) implies that the interval of attraction of \( \hat{w} \) with respect to \( h^{-1} \) is independent of \( h \). Let \( \hat{y} \) be one endpoint of this interval of attraction and let \( J \) be the interval in \( \Gamma \) with endpoints \( \hat{w} \) and \( \hat{y} \) which lies in the basin of \( \hat{w} \). The only fixed points of \( h \mid_J \) are the endpoints and \( \hat{w} \) is a repeller while \( \hat{y} \) is an attractor.

Now we show how to extract a (not necessarily unique) point \( y \in \bar{U} \) from \( \hat{y} \) that is fixed by each \( h \). By Corollary 11 and Theorem 13 of \([M]\) there is a sequence of disjoint closed arcs \( \hat{\alpha}_i \subset \bar{U} \) with interior \( \hat{\alpha}_i \subset U \) and endpoints in the frontier of \( U \) (in \( S^2 \)) and there exists \( y \) in the frontier of \( U \) such that

- \( \hat{\alpha}_i \to y \) (in the Hausdorff topology on \( S^2 \)
• there is a component \( Z_i \) of \((U \setminus \alpha_i)\) such that \( Z_{i+1} \subset Z_i \) and \( \cap_{i=1}^{\infty} Z_i = \emptyset \)

• \( \alpha \) extends to a closed arc \( \hat{\alpha}_i \) in \( \hat{U} \) such that \( \hat{\alpha}_i \) converges to \( \hat{y} \) (in the Hausdorff topology on \( \hat{U} \))

Clearly if we show \( h(\alpha_i) \cap \alpha_i \neq \emptyset \) then it follows that \( y \in \text{Fix}(h) \). One of the endpoints of \( \hat{\alpha}_i \), call it \( \hat{x}_i \), lies in \( J \). Since \( \hat{h} \) has no fixed points in the interior of \( J \) it follows that

\[
\lim_{n \to -\infty} \hat{h}^n(\hat{x}_i) = \hat{y} \quad \text{and} \quad \lim_{n \to -\infty} \hat{h}^n(\hat{x}_i) = \hat{w}.
\]

On the other hand each \( z \in \alpha_i \) lies in \( U \), the basin of attraction of \( p_1 \), so

\[
\lim_{n \to -\infty} h^n(z) = p_1.
\]

Since \( \hat{\alpha}_i \) separates \( \hat{y} \) and \( p_1 \) in \( \hat{U} \) we conclude that \( h^n(\alpha_i) \cap \alpha_i \neq \emptyset \) for large \( n \) (and hence also \( \alpha_i \cap h^{-n}(\alpha_i) \neq \emptyset \)). But this implies \( h^k(\alpha_i) \cap \alpha_i \neq \emptyset \) for all \( k \in \mathbb{Z} \) because \( h^k(\alpha_i) \cap \alpha_i = \emptyset \) and \( k \neq 0 \) would imply that for all \( n > 0 \) either \( h^{nk}(\alpha_i) \subset Z_i \) or \( h^{-nk}(\alpha_i) \subset Z_i \) which is a contradiction. Hence the point \( y \) is fixed by each \( h \).

Moreover, for any \( h \in \mathcal{H} \) we have \( h^k(\alpha_i) \cap \alpha_i \neq \emptyset \) for all \( k \in \mathbb{Z} \). This implies \( y \) is not an attractor for either \( h \) or \( h^{-1} \) since otherwise, choosing \( A = \alpha_i \) for some large \( i \), we would contradict Lemma 2.2-(2). We conclude \( y \) is not contained in \( \{p_1, \ldots, p_k\} \cup \{q_1, \ldots, q_k\} \).

3 Applications

**Proof of Theorem 1.2 and of Theorem 1.4** We assume the notation of Theorem 1.4 and allow the possibility that \( S_0 = S \).

We use the standard setup for discussing Nielsen classes in surfaces. The universal cover \( \tilde{S} \) of \( S \) is topologically the interior of a disk and is compactified to a closed disk \( D \) by the ‘circle at infinity’ \( S_\infty \). Every lift \( \tilde{g} : \tilde{S} \to \tilde{S} \) of every homeomorphism \( g : S \to S \) extends to a homeomorphism \( \tilde{g} : D \to D \). If an isotopy between \( g_1 \) and \( g_2 \) is lifted to an isotopy between lifts \( \tilde{g}_1 \) and \( \tilde{g}_2 \) then \( \tilde{g}_1|_{S_\infty} = \tilde{g}_2|_{S_\infty} \).

Choose a component \( \tilde{S}_0 \) of the full pre-image of \( S_0 \) in \( \tilde{S} \) and let \( C \) be the intersection of the closure of \( \tilde{S}_0 \) in \( D \) with \( S_\infty \). Then \( C \) is a Cantor set if \( S \neq S_0 \) and \( C = S_\infty \) if \( S = S_0 \). Since \( C \) contains at least three points there is at most one lift of any homeomorphism that pointwise fixes \( C \).

Given \( h \in \mathcal{H}_0 \) choose \( g : S \to S \) that is isotopic to \( h \) and pointwise fixes \( S_0 \) and let \( \tilde{g} : \tilde{S} \to \tilde{S} \) be the lift of \( g \) that pointwise fixes \( \tilde{S}_0 \). The isotopy from \( h \) to \( g \) lifts to an isotopy from \( \tilde{h} \) to a lift \( \tilde{g} \) of \( g \) satisfying \( \tilde{h}|_C = \tilde{g}|_C = \text{identity} \). The assignment \( h \to \tilde{h} \) defines a lift \( \tilde{\mathcal{H}}_0 \subset \text{Homeo}(D) \) of \( \mathcal{H}_0 \).

Given \( y \in \text{Fix}(\alpha^n) \cap S_0 \), choose a lift \( \tilde{y} \in \tilde{S}_0 \) of \( y \), let \( A : \tilde{S} \to \tilde{S} \) be the lift of \( \alpha^n \) that fixes \( \tilde{y} \) and note that \( A \) preserves \( \tilde{S}_0 \). Then \( C \) is \( \tilde{A} \)-invariant and \( \text{Fix}(\tilde{A}|_{S_\infty}) \) is a finite subset of \( C \) with more than two elements. Moreover, each point of \( \text{Fix}(\tilde{A}|_{S_\infty}) \)
is either an attracting or repelling fixed point for \( \hat{A} : D \to D \) (see, for example, Theorem 5.5 of [CB] or [HT]). The isotopy from \( \alpha^n \) to \( f^n \) lifts to an isotopy from \( A \) to a lift \( F \) of \( f^n \) such that \( \hat{F} = \hat{A} \). The commutator \([\hat{F}, \hat{h}]\) is the identity because it fixes each point in \( C \) and is the extension of a lift of \([f^n, h] = \text{identity}\). This proves that \( \hat{F} \) commutes with each \( \hat{h} \).

Theorem 1.4 applies to \( G = G_0 = \langle \hat{H}_0, F \rangle \). We conclude that there exists \( \tilde{x} \in \text{Fix}(\hat{H}_0) \cap \text{Fix}(F) \cap S \). The image \( x \in S \) of \( \tilde{x} \) satisfies the conclusions of the theorem.

Proof of Theorem 1.6 We assume that there is a faithful homomorphism \( L : \text{MCG}(S) \to \text{Diff}(S) \) satisfying (1) and (2) and prove that there is a non-trivial homomorphism from \( \mathcal{L}(\Gamma_1) \) to \( \mathbb{R} \), thereby contradicting the assumption that \( H^1(\Gamma_1) \) has rank zero.

By hypothesis, each \( h \in \mathcal{L}(\Gamma_1) \) is isotopic to a homeomorphism that is the identity on \( S_2 \) and \( f := \mathcal{L}(\mu) \) is isotopic to a homeomorphism \( \alpha \) such that \( \alpha(S_2) = S_2 \) and \( \alpha|_{S_2} \) is pseudo-Anosov. Also \( f \) commutes with each \( h \in \mathcal{L}(\Gamma_1) \) because \( \mu \) commutes with each element of \( \Gamma_1 \). Theorem 1.4 implies that \( \text{Fix}(\mathcal{L}(\Gamma_1)) \) is infinite.

Choose a non-isolated point \( x \) of \( \text{Fix}(\mathcal{L}(\Gamma_1)) \). The assignment \( h \to \det(Dh_x) \) defines a homomorphism from \( \mathcal{L}(\Gamma_1) \) to \( \mathbb{R} \). If this is non-trivial we are done. Otherwise, each \( Dh_x \) has determinant one. Since \( x \) is the limit of global fixed points there is a vector based at \( x \) that is fixed by each \( Dh_x \). Thus there is a basis for the tangent space of \( S \) at \( x \) with respect to which each \( Dh_x \) defines a homomorphism from \( \mathcal{L}(\Gamma_1) \) to \( \mathbb{R} \). If this is non-trivial we are done. Otherwise \( n_h = 0 \) and \( Dh_x \) is the identity for all \( h \in \mathcal{L}(\Gamma_1) \). The existence of a non-trivial homomorphism from \( \mathcal{L}(\Gamma_1) \) to \( \mathbb{R} \) now follows from the Thurston stability theorem ([Th], see also Theorem 3.4 of [Fr]).
