Abstract: We obtain limit theorems (Stable Laws and Central Limit Theorems, both standard and non-standard) and thermodynamic properties for a class of non-uniformly hyperbolic flows: almost Anosov flows, constructed here. The link between the pressure function and limit theorems is studied in an abstract functional analytic framework, which may be applicable to other classes of non-uniformly hyperbolic flows.

1. Introduction and Summary of the Main Results

This paper is a contribution to the theory of limit theorems and thermodynamic formalism in the context of non-uniformly hyperbolic flows on manifolds. In particular we introduce a new class of ‘almost Anosov flows’, a natural analogue of almost Anosov diffeomorphisms introduced in \cite{HY95}, and prove limit theorems for natural observables $\psi$ with respect to the SRB measure, also giving the form of the associated pressure function. This example is presented in the context of a general framework, which may be applicable to a range of other non-uniformly hyperbolic flows. We recall that various statistical properties for several classes of Anosov flows are known \cite{D98,D03,L04}, but none of these results apply to the class of ‘almost Anosov flows’ considered here.

Given a flow $\Phi_t$, with a real-valued potential $\phi$, we suppose that there is an equilibrium state $\mu_\phi$. A standard way of studying the behaviour of averages of a real-valued observable $\psi$ is to consider a Poincaré section $Y$ and study the induced first return map $F : Y \rightarrow Y$, the induced potentials $\bar{\phi}$ and $\bar{\psi}$, with the induced measure $\mu_{\bar{\phi}}$. In the discrete time case, in fact in the setting where all the dynamical systems are countable Markov shifts, \cite[Section 2]{S06} showed a one-to-one relation between limit laws for $\psi$ and the asymptotic form of the pressure function $P(\phi + s\psi)$, as $s \rightarrow 0$. This function experiences a phase transition at $s = 0$, and its precise form determines the type of limit laws (in particular, the index of the stable law), see \cite{MT04,Z07} and \cite[Theorem 7]{S06}. Furthermore, under certain conditions on $\psi$, \cite[Theorem 8]{S06} gave an asymptotically linear relation between the induced pressure $P(\phi + s\psi)$ and $P(\phi + s\psi)$. On the limit
theorems side, [MT04, Z07] and [S06, Theorem 7] show how one can go between results on the induced and on the original system: the first of these also applies in the flow setting. In these cases, the tail of the roof function/return time to the Poincaré section (both for the flow and the map) plays a major role in determining the form of the results. Here we will follow this paradigm in the setting of a new class of flows. The proofs of the main theorems are facilitated by corresponding theorems in an abstract functional analytic framework. Applying this to the considered example requires precise estimates on the tails of the roof function, which we prove for our main example.

Our central example is an almost Anosov flow, which is a flow having a continuous flow-invariant splitting of the tangent bundle $TM = E^u \oplus E^c \oplus E^s$ (where $E^c_q$ is the one-dimension flow direction) such that we have exponential expansion/contraction in the directions $E^u_q, E^s_q$, except for a finite number of periodic orbits (in our case a single orbit). We can think of these as perturbed Anosov flows, where the perturbation is local around these periodic orbits, making them neutral. A precise description is given in Sect. 2. Almost Anosov diffeomorphisms have been introduced in [HY95] and sufficiently precise estimates on the tail of the return function to a ‘good’ set have been obtained in [BT17]. (These estimates are for both finite and infinite measure preserving almost Anosov diffeomorphisms.) We emphasise that the roof function is not constant on the stable direction, which is a main source of difficulty. When considering these examples we choose $\phi$ so that $\mu_\phi$ is the SRB measure. We build on the construction in [BT17] to obtain the asymptotic of the tail behaviour of the roof functions for almost Anosov flows (when viewed as suspension flows). The main technical results for these systems are Propositions 2.2 and 2.4. These are then used to prove the main result Theorem 2.5.

For a major part of the statements of the abstract theorems in this paper (in contexts not restricted to almost Anosov flows) we do not require any Markov structure for our system: it is only when we want to see our results in terms of the pressure function (making the connection between the leading eigenvalue of the twisted transfer operator of the base map and pressure as in [S99, Theorem 4]) that this is needed. Our setup requires good functional analytic properties of the Poincaré map in terms of abstract Banach spaces of distributions. Using the rather mild abstract functional assumptions described in Sects. 4, 5 we obtain stable laws, standard and non-standard CLT; this is the content of Proposition 5.1. In Sect. 6 we recall [S06, Theorem 7] and [MT04, Theorem 1.3] to lift Proposition 5.1 to the flow, which allow us to prove Proposition 6.1.

In Sect. 7 we do exploit the assumption of the Markov structure to relate the definition of the pressure $P(\bar{\phi} + s \bar{\psi}), s \geq 0$, with that of the family of eigenvalues of the family of twisted transfer operators of the Poincaré map; the twist is in terms of the roof function of the suspension flow and the potential $\psi$. Using this type of identification, in Theorem 7.1 we relate the induced pressure $P(\tilde{\phi} + s \tilde{\psi})$ with the original pressure. Using the main result in Sects. 7, 8 we summarise the results for the abstract framework in the concluding Theorem 8.2, which gives the equivalence between the asymptotic behaviour of the pressure function $P(\phi + s \psi)$ and limit theorems. It is this summarising result that can be viewed as a version of Theorems 2–4 and Theorem 7 of [S06] combined, for flows.

We note that limit theorems for the almost Anosov flows studied here could have been obtained via the very recent results of limit laws for invertible Young towers as in [MV19, Theorem 3.1] together with the arguments of lifting limit laws from the suspension to the flow in [MT04, Z07] and [S06, Theorem 7]. Notably [MV19] applies to invertible Young towers and as such to several classes of billiard maps/flows. We conclude our introduction by noting some possible extensions: we do not approach the correspondence between the shape of the pressure and decay of correlations, but believe that such
a correspondence can be established using the present results and arguments/estimates in [MTe17,BMT18,BMT]. Moreover, for a large class of discrete time, infinite measure preserving systems, a version of [S06, Theorem 8] along with connection with limit theorems has been obtained in [BTT18]: we expect this to carry over to the case where the almost Anosov flow has infinite measure.

Organisation of the paper. In Sect. 2 we give the setup of the almost Anosov flow as ODE, and then translate it to a suspension flow over a Poincaré section. Proposition 2.4 computes the tails of the associated roof function. Section 2.3 gives the main limit theorems for the almost Anosov flow. Section 3 gives the preliminaries of equilibrium states and prove the limit laws for equilibrium states of the flow. Finally, the appendix gives some technical proofs for Sect. 5, and then concludes by checking all the hypotheses of the abstract results. In “Appendix A” we verify the abstract hypotheses of Proposition 5.1 and Theorem 8.2 for the almost Anosov flows introduced in Sect. 2 which allows us to complete the proofs of Theorems 2.5.

Notation. We use “big O” and \(\ll\) notation interchangeably, writing \(a_n = O(b_n)\) or \(a_n \ll b_n\) if there is a constant \(C > 0\) such that \(a_n \leq C b_n\) for all \(n \geq 1\). We write \(a_n \sim b_n\) if \(\lim_n a_n/b_n = 1\). Throughout we let \(\rightarrow^d\) stand for convergence in distribution. By \(\mathcal{F}\) being piecewise Hölder, etc., we mean that \(\mathcal{F}\) is Hölder on the elements \(a \in \mathcal{A}\), with a uniform exponent, but the Hölder norm of \(\mathcal{F}|_a\) is allowed to depend on \(a\).

2. The Setup for Almost Anosov Flows

2.1. Description via ODEs. Let \(\mathcal{M}\) be an odd-dimensional compact connected manifold without boundary. An almost Anosov flow is a flow having continuous flow-invariant splitting of the tangent bundle \(T\mathcal{M} = E^u \oplus E^c \oplus E^s\) (where \(E^c\) is the one-dimension flow direction) such that we have exponential expansion/contraction in the direction of \(E^u, E^s\), except for a finite number of periodic orbits (in our case a single orbit \(\Gamma\)). After restricting to an irreducible component if necessary, Anosov flows are automatically transitive, cf. [BS02, 5.10.3]. As noted in the introduction, we can think of almost Anosov flows as perturbed Anosov flows, where the perturbation is local around \(\Gamma\), making \(\Gamma\) neutral.

Let \(\Phi_t : \mathcal{M} \times \mathbb{R} \to \mathcal{M}\) be an almost Anosov flow on a 3-dimensional manifold. We assume that the flow in local Cartesian coordinates near the neutral periodic orbit \(\Gamma := (0,0) \times \mathbb{T}\) is determined by a vector field \(X : \mathcal{M} \to T\mathcal{M}\) defined as:

\[
\begin{pmatrix}
\dot{x} \\
\dot{y} \\
\dot{z}
\end{pmatrix} = X(x,y,z) = \begin{pmatrix}
x(a_0 x^2 + a_2 y^2) \\
y(b_0 x^2 + b_2 y^2) \\
1 + w(x,y)
\end{pmatrix}
\]

where\(^1\) \(a_0, a_2, b_0, b_2 \geq 0\) with \(\Delta = a_2 b_0 - a_0 b_2 \neq 0\), and \(w\) is a homogeneous function with exponent \(\rho \geq 0\) as leading term, cf. Remark 2.6. For the Limit Theorem 2.5, we

\(^1\) The notation and absence of mixed terms \(a_1x^y\) and \(b_1x^y\) goes back to [H00], who could not treat mixed terms. In [BT17], the mixed terms are absent too, in order to make the explicit form of the first integrals possible. Importantly, (2.1) ensure that the two vertical coordinate planes are local stable and unstable manifold of \(\Gamma\). The only linear transformation that preserves this are trivial scalings in the coordinate directions. Such scalings reduce \(b_2/a_2\) and \(a_0/b_0\) to single parameters, but we didn’t do this to maintain the possibility to compare proofs with [BT17,H00] more easily. It is possible to treat mixed terms to some extent, see [B19], but the additional required technicalities are beyond the purpose of this paper.
additionally require $a_2 > b_2$ (so that $\beta > 1$, the finite measure case). We will use a Poincaré section $\Sigma$ which is $\{z = 0\}$ in local coordinates near $\Gamma$, but which is thought to be defined across the whole manifold so that the Poincaré maps is defined everywhere on $\Sigma$. The Poincaré map of the Anosov flow (i.e., before the perturbation rendering $\Gamma$ neutral) is Anosov itself, and hence has a Markov partition, for instance based on arcs in $W^s(p) \cup W^u(p)$ for $p = (0, 0)$, but not $W^s_{\text{loc}}(p) \cup W^u_{\text{loc}}(p)$ because we want $p$ in the interior of a partition element. As the perturbation is local around $\Gamma$ and leaves local stable and unstable manifolds of $\Gamma$ unchanged, the same Markov partition can be used for the almost Anosov flow.

Let us call the horizontal (i.e., $(x, y)$-component) of the flow $\Phi^\text{hor}_t$. This is the vector field of [BT17, Equation (4)], with $\kappa = 2$ and the vertical component is added as a skew product. Therefore we can take some crucial estimates from the estimates of $\Phi^\text{hor}_t$ in [BT17, Proposition 2.1].

The flow $\Phi_t$ has a periodic orbit $\Gamma = \{p\} \times \mathbb{T}$ of period 1 (which is neutral because $DX$ is zero on $\Gamma$), and it has local stable/unstable manifolds $W^s_{\text{loc}}(\Gamma) = \{0\} \times (-\epsilon, \epsilon) \times \mathbb{T}$ and $W^u_{\text{loc}}(\Gamma) = (-\epsilon, \epsilon) \times \{0\} \times \mathbb{T}$. It is an equilibrium point of neutral saddle type if we only consider $\Phi^\text{hor}_t$. The time-1 map $\hat{f}$ of $\Phi^\text{hor}_t$ is an almost Anosov map, with Markov partition $\{\hat{P}_i\}_{i \geq 0}$, where we assume that $p$ is an interior point of $\hat{P}_0$.

Given $q \in \hat{f}^{-1}(\hat{P}_0)$, define

$$\hat{\tau}(q) := \min\{t > 0 : \Phi^\text{hor}_t(q) \in \hat{W}^s\},$$

(2.2)

where $\hat{W}^s$ is the stable boundary leaf of $\hat{P}_0$, see Fig. 1. Let $\hat{W}^u(y)$ denote the unstable leaf of $\hat{f}$ intersecting $(0, y) \in \hat{W}^s(p)$. The function $\hat{\tau}$ is strictly monotone on $\hat{W}^u(y)$. For
$y > 0$ and $T \geq 1$, let $\xi(y, T)$ denote the distance between $(0, y)$ and the (unique) point $q \in \hat{W}^u(y)$ with $\hat{t}(q) = T$. The crucial information from [BT17, Proposition 2.1] is
\[
|\xi(y, T) - \xi(y, T + 1)| = \beta \xi(y) - \beta^T T^{-(\beta + 1)}(1 + o(1)) \quad \text{as } T \to \infty, 
\]
for $\beta = (a_2 + b_2)/(2b_2)$ and specific values $\xi_0(y)$ given in [BT17, Proof Proposition 2.1]. The parameters $a_2, b_2 \geq 0$ can be chosen freely, so (2.3) holds for $\beta \in \left(\frac{1}{2}, \infty\right)$, but in this paper we choose $a_2 > b_2$, and therefore $\beta \in (1, \infty)$. Also the “small tail” estimates of (2.3) are stronger than the “big tail” estimates needed in our main theorems, but are required for particular results in the infinite measure setting of [BT17].

Remark 2.1. In fact, for the most general vector fields treated in [BT17, Equation (3)] (i.e., vector fields with higher order terms), we cannot do better than “big tails” estimates:
\[
\xi(y, T) = \xi_0(y) T^{-\beta} (1 + O(T^{-\beta_*} + T^{-\frac{1}{2}} \log T)), 
\]
for $\beta_* = \min\{1, a_2/b_2, b_0/a_0\}$, see [BT17, Lemma 2.3]. This is due to the perturbation arguments in [BT17, Section 2.4] that become necessary when higher order terms are present and a precise first integral from [BT17, Lemma 2.2] is not available. Since the horizontal part of vector field of (2.1) here is the ‘ideal’ vector field from [BT17, Equation (4)], our small tail estimate (2.3) becomes possible.

The next proposition gives an estimate of integrals along such curves. This allows us to estimate the tail of the roof function (when viewing $\Phi_t$ as a suspension flow) in Proposition 2.4 and also, the tail of induced potentials (see Remark 2.6). In the first instance we use it to estimate the vertical component of the flow $\Phi_t$ (compared to $t$).

Proposition 2.2. Let $\theta : \mathbb{R}^2 \to \mathbb{R}$ be a homogeneous function with exponent $\rho \in \mathbb{R}$ such that $\theta(x, 0) \neq 0 \neq \theta(0, y)$ for $x \neq 0 \neq y$. Then there is a constant $C_\rho > 0$ (given explicitly in the proof) such that for every $q$ with $\hat{t}(q) = T$ as in (2.2),
\[
\Theta(T) := \int_0^T \theta(\Phi_t(q), 0) \, dt = \begin{cases} 
C_\rho T^{1-\frac{1}{2}} (1 + o(1)) & \text{if } \rho < 2, \\
C_\rho \log(T)(1 + o(1)) & \text{if } \rho = 2, \\
C_\rho (1 + o(1)) & \text{if } \rho > 2.
\end{cases} 
\]

For the proof of Proposition 2.2 we recall some notation and the form of the first integral $L(x, y)$ from [BT17, Lemma 2.2], replacing $\kappa$ from that paper by 2. Recall that $\Delta := a_2 b_0 - a_0 b_2 \neq 0$. Let $u, v \in \mathbb{R}$ be the solutions of the linear equation
\[
\begin{cases} 
(u + 2)a_0 = v b_0 \\
(v + 2)b_2 = u a_2
\end{cases} \quad \text{that is:} \quad \begin{cases} 
u = \frac{2b_2}{\Delta} (a_0 + b_0), \\
\chi = \frac{2a_0}{\Delta} (a_2 + b_2).
\end{cases}
\]

Note that $u, v$ and $\Delta$ all have the same sign. Define:
\[
\beta_0 := \frac{a_0 + b_0}{2a_0} = \frac{u + v + 2}{2v}, \quad \beta := \frac{a_2 + b_2}{2b_2} = \frac{u + v + 2}{2u}, \quad c_0 = a_0 + b_0, \quad c_2 = a_2 + b_2.
\]

Note that $\frac{\beta_0}{\beta_2} = \frac{u}{v}, \frac{a_0 u}{b_2 v} = \frac{c_0}{c_2}$ and $\beta_0, \beta_2 > 1/2$ (or is $1/2$ if we allow $b_0 = 0$ or $a_2 = 0$ respectively). The content of [BT17, Lemma 2.2] is that
\[
L(x, y) = \begin{cases} 
x^u y^v (\frac{a_0}{v} x^2 + \frac{b_2}{u} y^2) & \text{if } \Delta > 0; \\
x^{-u} y^{-v} (\frac{a_0}{v} x^2 + \frac{b_2}{u} y^2)^{-1} & \text{if } \Delta < 0.
\end{cases}
\]
Fig. 2. The first quadrant of the rectangle $\hat{P}_0$, with the integral curve $I(T)$ connecting $(\xi(\eta, T), \eta) \in \hat{W}_{loc}^u(0, \eta)$ and $(\zeta'_0, \omega(\eta, T)) \in \hat{W}_{loc}^s(\zeta'_0, \omega(\eta, T))$.

is a first integral of (i.e., preserved by) $\Phi_{\text{hor}}^T$ (and therefore of $\Phi_T$).

For the proof of Proposition 2.2, we follow the proof of [BT17, Proposition 2.1]. In comparison, we have $\kappa$ from [BT17, Proposition 2.1] equal to 2, our current integrand is more complicated, but we only need first order error terms.

**Proof of Proposition 2.2.** Fix $\eta$ such that the local unstable leaf $\hat{W}_{loc}^u(0, \eta)$ intersects $\hat{f}^{-1}(\hat{P}_0) \setminus \hat{P}_0$. Recall from the text below (2.2) that, given $T$ large enough, there is a unique point $(\xi(\eta, T), \eta') \in \hat{W}_{loc}^u(0, \eta)$ such that

$$(\zeta'_0, \omega(\eta, T)) := \Phi_{\text{hor}}^T((\xi(\eta, T), \eta')) \in \hat{W}_{loc}^s(\zeta_0, 0),$$

where $\hat{W}_{loc}^s(\zeta_0, 0)$ is the local stable leaf forming the right boundary of $P_0$, see Fig. 2. Assuming $\hat{W}_{loc}^u(0, \eta)$ and $\hat{W}_{loc}^s(\zeta_0, 0)$ are straight horizontal and vertical lines respectively, induces a negligible error in these vertical coordinates, so in the rest of the proof, we write $\eta' = \eta$ and $\zeta'_0 = \zeta_0$.

For simplicity of notation, we will suppress the $\eta$ and $T$ in $\xi(\eta, T)$ and $\omega(\eta, T)$. For $0 \leq t \leq T$, let $\Phi_{\text{hor}}^T(\xi, \eta) = (x(t), y(t))$, so $(x(0)), y(0)) = (\xi, \eta)$ and $(x(T), y(T)) = (\zeta_0, \omega)$. We need to compute

$$\Theta(T) = \int_0^T \theta(x(t), y(t)) \, dt,$$

where $\theta : \mathbb{R}^2 \to \mathbb{R}$ is homogeneous of exponent $\rho$. 
New coordinates: We compute $\Theta(T)$ by introducing new coordinates $(L, M)$ where $L$ is the first integral from (2.8) (and hence independent of $t$), and $M(t) = y(t)/x(t)$, so $y(t) = M(t)x(t)$. For simplicity of notation, we suppress $t$ in $x$, $y$ and $M$. Differentiating to $\dot{y} = M\dot{x} + MX(t)$, and inserting the values for $\dot{x}$ and $\dot{y}$ from (2.1), we get

$$\dot{M} = -M(c_0 + c_2 M^2)x^2.$$  

(2.9)

We carry out the proof for $\Delta > 0$ (the case $\Delta < 0$ goes likewise), so the first integral is $L(x, y) = x^u y^v (\frac{a_0}{v} x^2 + \frac{b_2}{u} y^2)$ in (2.8). Since $(x, y)$ is in the level set $L(x, y) = L(\xi, \eta) = \xi^u \eta^v(\frac{a_0}{v} \xi^2 + \frac{b_2}{u} \eta^2)$, we can solve for $x^2$ in the expression

$$\xi^u \eta^v \left( \frac{a_0}{v} \xi^2 + \frac{b_2}{u} \eta^2 \right) = x^u y^v \left( \frac{a_0}{v} x^2 + \frac{b_2}{u} y^2 \right) = x^{u+2} \xi^u \eta^v \left( \frac{a_0}{v} + \frac{b_2}{u} M^2 \right).$$

Use (2.6) and (2.7) to obtain

$$\frac{a_0}{v} + \frac{b_2}{u} M^2 = \frac{\Delta}{2c_0 c_2} (c_0 + c_2 M^2)$$

and

$$\frac{a_0 \xi^2}{v} + \frac{b_2 \eta^2}{u} = \frac{\Delta}{2c_0 c_2} (c_0 \xi^2 + c_2 \eta^2).$$

Note also from (2.7) that $\frac{2v}{u + v + 2} = \frac{1}{\beta_0}$, $\frac{2u}{u + v + 2} = \frac{1}{\beta_2}$, and $\frac{2}{u + v + 2} = 1 - \frac{1}{\beta_0} - \frac{1}{\beta_2}$. This plus the previous two equations together gives

$$x^2 = G(T)M^{-\frac{1}{\beta_0}} (c_0 + c_2 M^2)^{\frac{1}{\beta_0}} = \frac{1}{\alpha_0} \eta^2 + \frac{1}{\beta_2} - 1,$$

with

$$G(T) := G(\xi(\eta, T), \eta) = \xi(\eta, T)^{\frac{1}{\beta_2}} \eta^{\frac{1}{\beta_0}} (c_0 \xi(\eta, T)^2 + c_2 \eta^2)^{1-\frac{1}{\beta_0} - \frac{1}{\beta_2}}.$$  

(2.10)

We claim that $G(T) \sim G_0 T^{-1}$ as $T \to \infty$ for some $G_0 > 0$.

Proving the claim: First note that

$$T = \int_{0}^{T} dt = \int_{M(0)}^{M(T)} \frac{dM}{M} = - \int_{M(T)}^{M(0)} \frac{dM}{M}.$$  

(2.12)

Recall that $M(0) = \eta/\xi$ and $M(T) = \omega/\xi_0$. Inserting this and (2.9) and (2.10) into (2.12) gives

$$\int_{\omega/\xi_0}^{\eta/\xi} \frac{dM}{M^{1-\frac{1}{\beta_0}} (c_0 + c_2 M^2)^{\frac{1}{\alpha_0}} + \frac{1}{\beta_2}} = G(T)T.$$  

(2.13)

As $T$ increases, the integral curve connecting $(\xi(\eta, T), \eta)$ to $(\xi_0, \omega(\eta, T))$ tends to the union of the local stable and unstable manifolds of $(0, 0)$, whilst $M(T) = \omega(\eta, T)/\xi_0 \to 0$ and $M(0) = \eta/\xi(\eta, T) \to \infty$. From their definition, $\xi(\eta, T)$ and $\omega(\eta, T)$ are decreasing in $T$, so their $T$-derivatives $\xi'(\eta, T), \omega'(\eta, T) \leq 0$.

Since $c_0, c_2 > 0$ (otherwise $\Delta = 0$), the integrand of (2.13) is $O(M^{\frac{1}{\beta_0} - 1})$ as $M \to 0$ and $O(M^{-\frac{1}{\beta_2} - 1})$ as $M \to \infty$. Hence the integral is increasing and bounded in $T$. But this means that $G(T)T$ is increasing in $T$ and bounded as well. Since by (2.11)

$$G(T)T = (\xi(\eta, T)T^{\beta_2})^{\frac{1}{\beta_2}} \eta^{\frac{1}{\beta_0}} (c_0 \xi(\eta, T)^2 + c_2 \eta^2)^{1-\frac{1}{\beta_0} - \frac{1}{\beta_2}},$$
we find by combining with (2.13) that

$$
\xi_0(\eta) := \lim_{T \to \infty} \xi(\eta, T) T^{\beta_2} = \lim_{T \to \infty} (G(T) T)^{\beta_2} \eta^{-\frac{\beta_2}{\rho_0}} (c_0 \xi(\eta, T)^2 + c_2 \eta^2)^{-\beta_2 (1 - \frac{1}{\rho_0} - \frac{1}{\eta})} 
$$

$$
= c_2^{-\frac{1}{\eta}} \eta^{-\frac{\beta_2}{\rho_2}} \left( \int_0^\infty \frac{dM}{M^{1-\frac{1}{\rho_0}} (c_0 + c_2 M^2)^{\frac{1}{\eta}} + \frac{1}{\rho_2}} \right)^{\beta_2},
$$

where we have used $-\beta_2 (1 - \frac{1}{\rho_0} - \frac{1}{\eta}) = -\frac{2\beta_2}{u + \frac{1}{\eta}} = -\frac{1}{u}$ for the exponent of $c_2$, and

$$
-\frac{\beta_2}{\rho_0} - 2\beta_2 (1 - \frac{1}{2\rho_0} - \frac{1}{2\rho_2}) = 1 - 2\beta_2 = -\frac{\alpha}{\rho_2} \quad \text{for the exponent of } \eta. \text{ This shows that }
$$

$$
G(T) \sim c_2^{-\frac{1}{\rho_0}} \eta^{-1} \xi_0(\eta)^{\frac{\beta_2}{2}} \eta^{-\frac{1}{\rho_2}} T^{-1} =: G_0 T^{-1} \text{ as } T \to \infty. \quad (2.14)
$$

**Estimating the integral** $\Theta(T)$: Recalling $M = y/x$ and using homogeneity of $\theta$, we have $\theta(x, y) = x^\rho \theta(1, M)$, and $\theta_0 := \theta(1, 0)$ and $\theta_\infty := \theta(0, 1) = \lim_{M \to \infty} M^{-\rho} \theta(1, M)$ are non-zero by assumption. Inserting the above into the integral of (2.13), and using (2.10) to rewrite $x$, we obtain

$$
\Theta(T) = G(T)^{\frac{\rho}{2} - 1} \int_{\omega/\xi_0}^{\eta/\xi_0} \frac{M^{-\frac{\rho}{2\rho_0}} (c_0 + c_2 M^2)^{-\frac{\rho}{2} (1 - \frac{1}{\rho_0} - \frac{1}{\eta})} \theta(1, M)}{M^{1-\frac{1}{\rho_0}} (c_0 + c_2 M^2)^{\frac{1}{\eta}} + \frac{1}{\rho_2}} dM. \quad (2.15)
$$

Set $\rho_0 := \frac{\rho}{2} - (1 + \frac{\rho}{2}) \left( \frac{1}{2\rho_0} + \frac{1}{2\rho_2} \right)$. The leading terms in the integrand of (2.15) are

$$
\begin{align*}
\theta_0 c_0^{\rho_0} M^{-1 + (1 - \frac{\rho}{2}) \frac{1}{\rho_0}} & \quad \text{as } M \to 0; \\
\theta_\infty c_2^{\rho_0} M^{-1 - (1 - \frac{\rho}{2}) \frac{1}{\rho_2}} & \quad \text{as } M \to \infty.
\end{align*} \quad (2.16)
$$

**The case** $\rho < 2$: By (2.16), we have for $\rho < 2$ that the exponent of $M$ is $> -1$ as $M \to 0$ and $< -1$ as $M \to \infty$. This means that the integral in (2.15) converges to some constant

$$
C^* = \int_0^\infty \frac{M^{-\frac{\rho}{2\rho_0}} (c_0 + c_2 M^2)^{-\frac{\rho}{2} (1 - \frac{1}{\rho_0} - \frac{1}{\eta})} \theta(1, M)}{M^{1-\frac{1}{\rho_0}} (c_0 + c_2 M^2)^{\frac{1}{\eta}} + \frac{1}{\rho_2}} dM
$$

as $T \to \infty$, and $\Theta \sim C^* G(T)^{\frac{\rho}{2} - 1} \sim C_\rho T^{-\frac{\rho}{2}}$ for $C_\rho = \left( c_2^{-1} \frac{1}{\rho_0} - \frac{1}{\eta} \xi_0(\eta)^{\frac{\rho}{2}} \eta^{-\frac{1}{\rho_2}} \right)^{\frac{\rho}{2} - 1} C^*$ by (2.11). This finishes the proof for $\rho < 2$.

**The case** $\rho > 2$: The value of $\Theta(T)$ based on the leading terms (2.16) of the integrand only is

$$
\Theta(T) \sim \frac{G(T)^{\frac{\rho}{2} - 1}}{\rho / 2 - 1} \left( \beta_0 \theta_0 c_0^{\rho_0} \left( \frac{\omega}{\xi_0} \right)^{(1 - \frac{\rho}{2}) \frac{1}{\rho_0}} + \beta_2 \theta_\infty c_2^{\rho_0} \left( \frac{\eta}{\xi_0} \right)^{-\frac{1}{\rho_2}} \right).
$$

Insert $\xi = \xi_0(\eta) T^{-\beta_2} (1 + o(1))$ and $\omega = \omega_0(\eta) T^{-\beta_0} (1 + o(1))$ from [BT17, Proposition 2.1]:

$$
\Theta(T) \sim \frac{G(T)^{\frac{\rho}{2} - 1}}{\rho / 2 - 1} \left( \beta_0 \theta_0 c_0^{\rho_0} \left( \frac{\xi_0}{\omega_0(\eta)} \right)^{\frac{\rho}{2} - 1} + \beta_2 \theta_\infty c_2^{\rho_0} \left( \frac{\eta}{\xi_0(\eta)} \right)^{\frac{\rho}{2} - 1} \right) T^{\frac{\rho}{2} - 1}.
$$
Next, by inserting the asymptotics of $G(T)$ from (2.14), the factor $T^{\frac{\rho - 1}{2}}$ cancels:

$$\Theta(T) \sim C_{\rho} := \frac{G_0^{\rho - 1}}{2 - 1} \left( \beta_0 \theta_0 c_{\rho_0}^{\rho_0} \left( \frac{\xi_0}{\omega_0(\eta)} \right)^{\rho/2 - 1} + \beta_2 \theta_\infty c_{2}^{\rho_2} \left( \frac{\eta}{\xi_0(\eta)} \right)^{\rho/2 - 1} \right).$$

The case $\rho = 2$: The factor $G(T)^{\frac{\rho - 1}{2}}$ in (2.15) now disappears and the leading terms (2.16) are $\theta_0 c_{\rho_0}^{\rho_0} M^{-1}$ and $\theta_\infty c_{2}^{\rho_2} M^{-1}$ respectively. This gives

$$\Theta(T) \sim \int_{\omega/\xi_0}^{\eta/\xi_0} \frac{\theta_0 c_{\rho_0}^{\rho_0} + \theta_\infty c_{2}^{\rho_2}}{M} dM = \left( \theta_0 c_{\rho_0}^{\rho_0} + \theta_\infty c_{2}^{\rho_2} \right) \left( \log \frac{\eta}{\xi} - \log \frac{\omega}{\xi_0} \right).$$

Inserting again the values of $\xi$ and $\omega$ from [BT17, Proposition 2.1] gives

$$\Theta(T) \sim \left( \theta_0 c_{\rho_0}^{\rho_0} + \theta_\infty c_{2}^{\rho_2} \right) (\beta_0 + \beta_2) \log T \quad \text{as } T \to \infty.$$

This completes the proof. \qed

2.2. Description via suspension flows, tail estimates of the roof function. The 3-dimensional time-1 map $\Phi_1$ preserves no 2-dimensional submanifold of $\mathcal{M}$. Yet in order to model $\Phi_t$ as a suspension flow over a 2-dimensional map, we need a genuine Poincaré map. For this we choose a section $\Sigma$ transversal to $\Gamma$ and containing a neighbourhood $U$ of $p$. As an example, $\Sigma$ could be $\mathbb{T}^2 \times \{0\}$, and the Poincaré map to $\mathbb{T}^2 \times \{0\}$ could be (a local perturbation of) Arnol’d’s cat map; in this case (and most cases) $\mathcal{M}$ is not homeomorphic to $\mathbb{T}^3$ because the homology is more complicated, see [BF13,N76].

Let $h : \Sigma \to \mathbb{R}^+$, $h(q) = \min\{t > 0 : \Phi_t(q) \in \Sigma\}$ be the first return time. Assuming that $\sup_{\Sigma} |w(x, y)| < 1$, the first return time $h$ is bounded and bounded away from zero, i.e., $0 < \inf_{\Sigma} h < \sup_{\Sigma} h$. There is no loss of generality in assuming that $\inf_{\Sigma} h \geq 1$.

The Poincaré map $f := \Phi_h : \Sigma \to \Sigma$ has a neutral saddle point $p$ at the origin. Its local stable/unstable manifolds are $W^s_{loc}(p) = \{0\} \times (-\epsilon, \epsilon)$ and $W^u_{loc}(p) = (-\epsilon, \epsilon) \times \{0\}$. Because the flow $\Phi_t$ is a perturbation of an Anosov flow, and $f$ is a Poincaré map, it has a finite Markov partition $\{P_i\}_{i \geq 0}$ and we can assume that $p$ is in the interior of $P_0$. In the sequel, let $U$ be a neighbourhood of $p$ that is small enough that (2.1) is valid on $U \times \{0, 1\}$ but also that $f(U) \supset P_0 \cup P_0$.

In order to regain the hyperbolicity lacking in $f$, let

$$r(q) := \min\{n \geq 1 : f^n(q) \in Y\} \quad \text{(2.17)}$$

be the first return time to $Y := \Sigma \setminus P_0$. Then the Poincaré map $F = f^r = \Phi_r$ of $\Phi_t$ to $Y \times \{0\}$ is hyperbolic (see [H00, Section 7]), where

$$\tau(q) = \min\{t > 0 : \Phi_t((q, 0)) \in Y \times \{0\}\} = \sum_{j=0}^{r-1} h \circ f^j$$

is the corresponding first return time.

Consequently, the flow $\Phi_t : \mathcal{M} \times \mathbb{R} \to \mathcal{M}$ can be modelled as a suspension flow on $Y^* = \left( \bigcup_{q \in Y} \{q \} \times [0, \tau(q)) \right) / \sim \sim (F(q), 0)$. Since the flow and section $Y \times \{0\}$ are $C^1$ smooth, $\tau$ is $C^1$ on each piece $\{r = k\}$. 
Lemma 2.3. In the notation of Proposition 2.2 with \( \theta = w \) from the z-component in (2.1), we have \( \tau(q) = \hat{\tau}(q) + O(1) \), \( r = \hat{\tau}(q) + \Theta(\hat{\tau}(q)) + O(1) \) and \( \Theta(\hat{\tau}(q)) = o(\hat{\tau}(q)) \) as \( q \to 0 \).

**Proof.** By the definition of \( \hat{\tau} \) we have \( \Phi_{1} \hat{\tau}(q) \in \hat{W}^{s} \). Therefore it takes a bounded amount of time (positive or negative) for \( \Phi_{1} \hat{\tau}(q, 0) \) to hit \( Y \times \{0\} \), so \( |\tau(q) - \hat{\tau}(q)| = O(1) \).

If in (2.5) we set \( \theta = w \), then \( \hat{\tau}(q) + \Theta(\hat{\tau}(q)) \) indicates the vertical displacement under the flow \( \Phi_{1} \). In particular, it gives the number of times the flow-line intersects \( \Sigma \), and hence \( r = \hat{\tau}(q) + \Theta(\hat{\tau}(q)) + O(1) \). \( \square \)

Let \( \phi: Y^{r} \to \mathbb{R} \), \( \phi(q) = \lim_{t \to 0} -\frac{1}{t} \log |\Phi_{1}^{t}|_{W^{u}}(q)| \) be the potential for the SRB measure of the flow. Let \( \mu_{\phi} \) be the \( F \)-invariant equilibrium measure of the potential \( \bar{\phi}: Y \to \mathbb{R}, \bar{\phi}(q) = \int_{0}^{\tau(q)} \phi \circ \Phi_{1}(q) \, dt = -\log |D\Phi_{1}|_{W^{u}}(q)| \); so \( \bar{\phi} \) is the logarithm of the derivative in the unstable direction of the Poincaré map \( F \). This is at the same time the SRB-measure for \( F \) and thus is absolutely continuous conditioned to unstable leaves.

**Proposition 2.4.** Recall that \( \beta = \frac{a_{2} + b_{2}}{2b_{2}} \in \left(\frac{1}{2}, \infty\right) \). There exists \( C^{*} > 0 \) such that

\[
\mu_{\phi}(\{\tau > t\}) = C^{*}t^{-\beta}(1 + o(1)) \tag{2.18}
\]

for the \( F \)-invariant SRB measure \( \mu_{\bar{\phi}} \).

**Proof.** The function \( \tau \) is defined on \( \Sigma \setminus P_{0} \) and \( \tau \geq h_{2} = h + h \circ f \) on \( Y_{[r \geq 2]} := f^{-1}(P_{0}) \setminus P_{0} \). The set \( Y_{[r \geq 2]} \) is a rectangle with boundaries consisting of two stable and two unstable leaves of the Poincaré map \( f \). Let \( W^{u}(Y) \) denote the unstable leaf of \( f \) inside \( Y_{[r \geq 2]} \) with \((0, y)\) as (left) boundary point. Let \( y_{1} < y_{2} \) be such that \( W^{u}(y_{1}) \) and \( W^{u}(y_{2}) \) are the unstable boundary leaves of \( Y_{[r \geq 2]} \).
The unstable foliation of \( \hat{f} = \Phi^h_1 \) does not entirely coincide with the unstable foliation of \( f \). Let \( \hat{W}^u(y) \) denote the unstable leaf of \( \hat{f} \) with \((0, y)\) as (left) boundary point. Both \( \hat{W}^u(y) \) and \( W^u(y) \) are \( C^1 \) curves emanating from \((0, y)\); let \( \gamma(y) \) denote the angle between them. Then the lengths

\[
\text{Leb}(W^u(y) \cap \{ \tau > t \}) = |\cos \gamma(y)| \text{Leb}(\hat{W}^u(y) \cap \{ \tau > t \})(1 + o(1))
\]

as \( t \to \infty \), where the last equality and the notation \( \xi_0(y) \) and \( \beta = (a_2 + b_2)/(2b_2) \) come from (2.3).

We decompose the measure \( \mu_{\hat{f}} \) on \( Y_{[r \geq 2]} \) as

\[
\int_{Y_{[r \geq 2]}} v \, d\mu_{\hat{f}} = \int_{Y_1}^{Y_2} \left( \int_{W^u(y)} v \, d\mu_{W^u(y)} \right) \, dv^u(y).
\]

The conditional measures \( \mu_{W^u(y)} \) on \( W^u(y) \) are equivalent to Lebesgue \( m_{W^u(y)} \) with density \( h^u_0 = \frac{d\mu_{W^u(y)}}{dm_{W^u(y)}} \) tending to a constant \( h_*(y) \) at the boundary point \((0, y)\). Therefore, as \( t \to \infty \),

\[
\mu_{\hat{f}}(\tau > t) = \int_{Y_1}^{Y_2} \mu_{W^u(y)}(W^u(y) \cap \{ \tau > t \}) \, dv^u(y)
\]

\[
= \int_{Y_1}^{Y_2} h^u_0 \, m_{W^u(y)}(W^u(y) \cap \{ \tau > t \}) \, dv^u(y)
\]

\[
= \int_{Y_1}^{Y_2} h^u_0 |\cos \gamma(y)| \, m_{\hat{W}^u(y)}(\hat{W}^u(y) \cap \{ \tau > t \})(1 + o(1)) \, dv^u(y)
\]

\[
= \int_{Y_1}^{Y_2} h^u_0 |\cos \gamma(y)| \, \xi_0(y) \, t^{-\beta} (1 + o(1)) \, dv^u(y) = C^* t^{-\beta} (1 + o(1)),
\]

for \( C^* = \int_{Y_1}^{Y_2} h_*(y) |\cos \gamma(y)| \, \xi_0(y) \, dv^u(y) \), and using (2.3) in the third line. This proves the result. \( \square \)

2.3. Main results for the Poincaré map \( F \) and flow \( \Phi_t \). Throughout this section we assume the setup and notation of Sect. 2.2. We emphasise that we are in the finite measure setting, so

\[
\tau^* := \int_Y \tau \, d\mu_{\hat{f}} < \infty. \tag{2.19}
\]

We recall that the natural potential associated to the SRB-measure for \( F \) is \( \bar{\phi} = -\log |DF|_{W^u} \), which is the induced version of \( \phi = \lim_{t \to 0} -\log |D\Phi_t||_{W^u} \). Our main result can be viewed as a version of the results in [S06] for the flow \( \Phi_t \); it gives the link between limit theorems for \((\Phi_t, \psi)\) for (unbounded from below) potentials \( \psi \) on \( \mathcal{M} \) and pressure function \( \mathcal{P}(\phi + s\psi) \), \( s \geq 0 \). We let \( \psi + s\bar{\psi}, s \geq 0 \) be the family of induced potentials and denote the associate pressure function by \( \mathcal{P}(\bar{\phi} + s\bar{\psi}) \). Some background on equilibrium states and pressure function (along with their induced versions) is recalled in Sect. 3.
Theorem 2.5. Suppose \( \tilde{\psi}(y) := \int_0^T \psi \circ \Phi_t \, dt = C' - \psi_0 \) where \( C' > 0 \) and \( \psi_0 \) is positive piecewise \( C^1(\mathcal{Y}) \). Let \( \beta > 1 \) be as in Proposition 2.4. Furthermore, suppose that \( \mu_\beta(\psi_0 > t) \sim c t^{-\frac{\beta}{\kappa}} \) for some \( c > 0 \) and \( \kappa \in (1/\beta, \beta) \). Set \( \mu_\beta = \int_0^\infty \tilde{\psi} \, d\mu_\beta \) and let \( \psi_T = \int_0^T \tilde{\psi} \circ \Phi_t \, dt \). The following hold as \( T \to \infty \), w.r.t. \( \mu_\beta \).

(a) (i) When \( \beta < 2 \) and \( \kappa \in (\beta/2, \beta) \), set \( b(T) \) such that \( T \left( \frac{\beta}{(c b(T))^2} \right) \to 1 \).

Then \( \frac{1}{b(T)} (\psi_T - \psi_\ast \cdot T) \to^d G_{\beta/\kappa} \), where \( G_{\beta/\kappa} \) is a stable law of index \( \beta/\kappa \) and this is, further, equivalent to \( \mathcal{P}(\phi + s \psi) = \psi_\ast s + c s^{\beta/\kappa}(1 + o(1)) \), as \( s \to 0 \).

(ii) When \( \beta \leq 2 \) but \( \kappa = \beta/2 \), set \( b(T) \sim c^{-1/2} \sqrt{T \log T} \).

Then \( \frac{1}{b(T)} (\psi_T - \psi_\ast \cdot T) \to^d \mathcal{N}(0, 1) \) and this is, further, equivalent to \( \mathcal{P}(\phi + s \psi) = \psi_\ast s + c s^2 \log(1/s)(1 + o(1)) \), as \( s \to 0 \).

(b) Suppose that \( \beta > 2 \). Then there exists \( \sigma \neq 0 \) such that \( \frac{1}{\sqrt{T}} (\psi_T - \psi_\ast \cdot T) \to^d \mathcal{N}(0, \sigma^2) \) and this is, further, equivalent to \( \mathcal{P}(\phi + s \psi) = \psi_\ast s + \frac{\sigma^2}{2} s^2(1 + o(1)) \) as \( s \to 0 \). Moreover, \( \mathcal{P}(\phi + s \psi) = \frac{1}{\tau} \mathcal{P}(\phi + s \psi)(1 + o(1)) \).

Remark 2.6. If \( \psi : \mathcal{M} \to \mathbb{R} \) satisfies the following properties, then the condition on \( \tilde{\psi} \) in Theorem 2.5 holds. In local tubular coordinates near \{p\} \times \mathbb{T}, \psi = g_0 - g(W(x, y)) \) where \( g_0 \) is Hölder function vanishing on a neighbourhood of \( p \), and \( W(x, y) \) is a linear combination of homogeneous functions depending only on \( (x, y) \), such that the term \( W_\rho(x, y) \) with lowest exponent \( \rho \) satisfies \( W_\rho(0, 1) \neq 0 \neq W_\rho(1, 0) \), and \( g : \mathbb{R} \to \mathbb{R} \) is analytic with \( g(0) = 0, g'(0) \neq 0 \). Then \( \kappa = 1 - \frac{\rho}{2} \) (see Proposition 2.2), so assuming that this lowest exponent \( \rho \in (2(1 - \beta), 2(\beta - 1)/\beta) \), then \( \kappa \in (\frac{1}{\beta}, \beta) \).

Proof of Theorems 2.5. This follow directly from applying Theorem 8.2 (\( \Phi_t, \phi \)), which uses a special case of Proposition 5.1. “Appendix A” verifies all the abstract hypotheses of Proposition 5.1 and Theorem 8.2 for the flow \( \Phi_t \), with base map \( F \) and roof function \( \tau \) introduced in Sect. 2 and potential \( \psi \) defined in the statement of Theorem 2.5. The extra assumptions (including coboundary assumptions) that ensure \( \sigma \neq 0 \) in Proposition 5.1(ii) and Theorem 8.2 (b) are verified in “Appendix A.3”.

3. Background on Equilibrium States for Suspension Flows

Here we outline the standard general theory of thermodynamic formalism for suspension flows. We start with a discrete time dynamical system \( F : Y \to Y \). Defining \( \mathcal{M}_F \) to be the set of \( F \)-invariant probability measures, for a potential \( \psi : Y \to [-\infty, \infty] \) we define the pressure as

\[
\mathcal{P}(\psi) := \sup \left\{ h(\mu) + \int \psi \, d\mu : \mu \in \mathcal{M}_F \text{ and } -\int \psi \, d\mu < \infty \right\}.
\]

Given a roof function \( \tau : Y \to \mathbb{R}^+ \), let \( Y^\tau = \{(y, z) \in Y \times \mathbb{R} : 0 \leq z \leq \tau(y)\} \sim \) where \( (y, \tau(y)) \sim (Fy, 0) \). Then the suspension flow \( F_t : Y^\tau \to Y^\tau \) is given by \( F_t(y, z) = (y, z + t) \) computed modulo identifications. We will suppose throughout that \( \inf \tau > 0 \), but note that the case \( \inf \tau = 0 \) can also be handled, see for example [Sav98, IJT15]. Barreira and Iommi [BI06] define pressure as

\[
\mathcal{P}(\phi) := \inf \{ u \in \mathbb{R} : \mathcal{P}(\phi - u\tau) \leq 0 \} \quad (3.1)
\]
in the case that \((Y, F)\) is a countable Markov shift and the potential \(\phi : Y^\tau \to \mathbb{R}\) induces to \(\bar{\phi} : Y \to \mathbb{R}\), where

\[
\bar{\phi}(x) := \int_0^{\tau(x)} \phi(x, t) \, dt,
\]

(3.2)

has summable variations. This also makes sense for general suspension flows, so we will take (3.1) as our definition. In [AK42], there is a bijection between \(F_t\)-invariant probability measures \(\mu\), and the corresponding \(F\)-invariant probability measures \(\bar{\mu}\) given by the identification

\[
\mu = \frac{\bar{\mu} \times m}{(\bar{\mu} \times m)(Y^\tau)},
\]

where \(m\) is Lebesgue measure. That is, whenever there is such a \(\mu\) there is such a \(\bar{\mu}\), and vice versa. Moreover, Abramov’s formula for flows [Ab59b] gives the following characterisation of entropy:

\[
h(\mu) = \frac{h(\bar{\mu})}{(\bar{\mu} \times m)(Y^\tau)},
\]

(3.3)

and clearly

\[
\int \phi \, d\mu = \int \bar{\phi} \, d\bar{\mu} = \int \bar{\phi} \, d\bar{\mu}.
\]

(3.4)

One consequence of these formulas is that the pressure in (3.1) is independent of the choice of cross section \(Y\). This follows essentially from the fact that if we choose a subset of \(Y\) and reinduce there, then Abramov’s formula gives the same value for pressure (here we can use the discrete version of Abramov’s formula [Ab59a]). Note that we say ‘Abramov’s formula’ in both the continuous and discrete time cases as the formulas are analogous [Ab59a,Ab59b], and similarly for integrals, where the formula holds by the ergodic and ratio ergodic theorems.

We say that \(\mu_{\phi}\) is an equilibrium state for \(\phi\) if \(h(\mu_{\phi}) + \int \phi \, d\mu_{\phi} = \mathcal{P}(\phi)\). The same notion extends to the induced system \((Y, F, \bar{\phi})\). In that setting we may also have a conformal measure \(m_{\bar{\phi}}\) for \(\bar{\phi}\). This means that \(m_{\bar{\phi}}(F(A)) = \int_A e^{-\bar{\phi}} \, dm_{\bar{\phi}}\) for any measurable set \(A\) on which \(F\) is injective. Later on, in order to link our limit theorem results with pressure, we will assume that \(F : Y \to Y\) is Markov. In that setting our assumptions on \(\phi\) will be equivalent to assuming \(\mathcal{P}(\phi) = 0\), in which case we will have a equilibrium states and conformal measures \(\mu_{\bar{\phi}}\) and \(m_{\bar{\phi}}\).

### 4. Abstract Setup

We start with a flow \(f_t : M \to M\), where \(M\) is a manifold. Let \(Y\) be a co-dimension 1 section of \(M\) and define \(\tau : Y \to \mathbb{R}_+\) to be a roof function. We think of \(\tau\) as a first return of \(f_t\) to \(Y\) and define \(F : Y \to Y\) by \(F = f_{\tau}\). The flow \(f_t\) is isomorphic with the suspension flow \(F_t : Y^\tau \to Y^\tau\), \(Y^\tau = \{(y, z) \in Y \times \mathbb{R} : 0 \leq z \leq \tau(z)\}/\sim\), as described in Sect. 3. Throughout, we assume that \(\tau\) is bounded from below.

Given the potential \(\phi : M \to \mathbb{R}\) and its induced version \(\bar{\phi} : Y \to \mathbb{R}\) defined in (3.2), we assume that there is a conformal measure \(m_{\bar{\phi}}\) for \((F, \bar{\phi})\). In the rest of this section we recall the abstract framework and hypotheses in [LT16] as relevant for studying limit theorems.
4.1. Banach spaces and equilibrium measures for \((F, \phi)\) and \((f_t, \phi)\).

Let \(R_0 : L^1(m_\phi) \to L^1(m_\phi)\) be the transfer operator for the first return map \(F : Y \to Y\) w.r.t. conformal measure \(m_\phi\), defined by duality on \(L^1(m_\phi)\) via the formula \(\int_Y R_0 w \, dm_\phi = \int_Y w \circ F \, dm_\phi\) for every bounded measurable \(w\).

We assume that there exist two Banach spaces of distributions \(B, B_w\) supported on \(Y\) such that for some \(\alpha, \alpha_1 > 0\)

\((\text{H1})\)

(i) \(C^\alpha \subset B \subset B_w \subset (C^{\alpha_1})'\), where \((C^{\alpha_1})'\) is the dual of \(C^{\alpha_1} = C^{\alpha_1}(Y, \mathbb{C})\).

(ii) \(\bar{h} \in B\) for all \(h \in B, \, g \in C^\alpha\).

(iii) The transfer operator \(R_0\) associated with \(F\) maps continuously from \(C^\alpha\) to \(B\) and \(R_0\) admits a continuous extension to an operator from \(B\) to \(B\), which we still call \(R_0\).

(iv) The operator \(R_0 : B \to B\) has a simple eigenvalue at 1 and the rest of the spectrum is contained in a disc of radius less than 1.

A few comments on (H1) are in order and here we just recall the similar ones in [LT16].

We note that (H1)(i) should be understood in terms of the following usual convention (see, for instance, [GL06,DL08]): there exist continuous injective linear maps \(\pi_i\) such that \(\pi_1(C^\alpha) \subset B, \pi_2(B) \subset B_w\) and \(\pi_3(B_w) \subset (C^{\alpha_1})'\). Throughout, we leave such maps implicit, but recall their meaning here. In particular, we assume that \(\pi = \pi_3 \circ \pi_2 \circ \pi_1\) is the usual embedding, i.e., for all \(h \in C^\alpha\) and \(g \in C^{\alpha_1}\)

\[\langle \pi(h), g \rangle_0 = \int_Y \bar{h} g \, dm_\phi.\]

Via the above identification, the conformal measure \(m_\phi\) can be identified with the constant function 1 both in \((C^{\alpha_1})'\) and in \(B\) (i.e., \(\pi(1) = m_\phi\)). Also, by (H1)(i), \(B' \subset (C^\alpha)'\), hence the dual space can be naturally viewed as a space of distributions. Next, note that \(B' \supset (C^{\alpha_1})'' \supset C^{\alpha_1} \ni 1\), thus we have \(m_\phi \in B'\) as well. Moreover, since \(m_\phi \in B\) and

\[\langle 1, g \rangle_0 = \langle g, 1 \rangle_0 = \int g \, d\mu_\phi, \quad m_\phi\]

can be viewed as the element 1 of both spaces \(B\) and \((C^{\alpha_1})'\).

By (H1), the spectral projection \(P_0\) associated with the eigenvalue 1 is defined by \(P_0 = \lim_{n \to \infty} R_0^n\). Note that by (H1)(ii), for each \(g \in C^\alpha, \, P_0 g \in B\) and

\[\langle P_0 g, 1 \rangle_0 = m_\phi(P_0 g) = \lim_{n \to \infty} m_\phi(1 \cdot R_0^n g) = m_\phi(g) = \langle g, 1 \rangle_0.\]

By (H1)(iv), there exists a unique \(\mu_\phi \in B\) such that \(R_0 \mu_\phi = \mu_\phi\) and \(\langle \mu_\phi, 1 \rangle = 1\). Thus, \(P_0 g = \mu_\phi \langle g, 1 \rangle_0\). Also \(R_0' m_\phi = m_\phi\) where \(R_0'\) is dual operator acting on \(B'\). Note that for any \(g \in C^{\alpha_1}\),

\[|\langle \mu_\phi, g \rangle_0| = |\langle P_0 1, g \rangle_0| = \left| \lim_{n \to \infty} R_0^n m_\phi(g) \right| = \lim_{n \to \infty} \left| m_\phi(g \circ F^n) \right| \leq |g|_\infty.\]

Hence \(\mu_\phi\) is a measure. For each \(g \geq 0\),

\[\langle P_0 1, g \rangle_0 = \lim_{n \to \infty} \langle R_0^n 1, g \rangle = \lim_{n \to \infty} \langle 1, g \circ F^n \rangle_0 \geq 0.\]

It follows that \(\mu_\phi\) is a probability measure.

Summarising the above, the eigenfunction associated with the eigenvalue \(\lambda = 1\) is an invariant probability measure for \(F\) given by \(d\mu_\phi = h_0 \, dm_\phi\) where \(P_0 1 = h_0\). Using

\[\text{We will use systematically a “prime” to denote the topological dual.}\]
that $\pi(1) = m_\bar{\phi}$ we also have $P_01 = \mu_\bar{\phi}$. Under (H1), the standard theory summarised in Sect. 3 applies $P(\bar{\phi}) = \log \lambda = 0$. So, under (H1), $\mu_\bar{\phi}$ is an equilibrium (probability) measure for $(F, \bar{\phi})$. Further, via (3.4),

$$\mu_\phi = \frac{\mu_\bar{\phi} \times m}{(\mu_\bar{\phi} \times m)(Y^t)}$$

gives an equilibrium (probability) measure for $(f_1, \phi)$.

4.2. Transfer operator $R$ defined w.r.t. the equilibrium measure $\mu_\bar{\phi}$. Given the equilibrium measure $\mu_\bar{\phi} \in \mathcal{B}$, we let $R : L^1(\mu_\bar{\phi}) \to L^1(\mu_\bar{\phi})$ be the transfer operator for the first return map $F : Y \to Y$ w.r.t. the invariant measure $\mu_\bar{\phi}$ given by

$$\int_Y R v \, d\mu_\bar{\phi} = \int_Y v \, d\mu_\bar{\phi} \circ F$$

every bounded measurable $v$.

Under (H1)(i)–(iv), we further assume

(H1)(v) The transfer operator $R$ maps continuously from $C^\alpha$ to $B$ and $R$ admits a continuous extension to an operator from $B$ to $B$, which we still call $R$.

By (H1)(iv) and (H1)v, the operator $R : B \to B$ has a simple eigenvalue at 1 and the rest of the spectrum is contained in a disc of radius less than 1. While the spectra of $R_0$ and $R$ are the same, the spectral projection $P = \lim_{n \to \infty} R^n$ acts differently on $B, B_w$. In particular, $P1 = 1$, while $P01 = \mu_\bar{\phi}, P01 = h_0$. Throughout the rest of this paper, for any $g \in C^\alpha$, we let

$$\langle g, 1 \rangle := \langle g, P01 \rangle_0 = \langle P01, g \rangle_0 = \int_Y g \, d\mu_\bar{\phi}$$

and note that $P0g = h \langle g, 1 \rangle_0$ and $Pg = \langle g, 1 \rangle$.

4.3. Further assumptions on the transfer operator $R$. Given $R$ as defined in Sect. 4.2, for $u \geq 0$ and $\tau : Y \to \mathbb{R}_+$ we define the perturbed transfer operator

$$\hat{R}(u)v := R(e^{-u\tau}v).$$

By [BMT, Proposition 4.1], a general proposition on twisted transfer operators that holds independently of the specific properties of $F$, we can write for sufficiently small positive $u$,

$$\hat{R}(u) = r_0(u) \int_0^\infty M(t) e^{-ut} \, dt \quad \text{with} \quad M(t) := R(\omega(t - \tau)),$$

where $\omega : \mathbb{R} \to [0, 1]$ is an integrable function with supp $\omega \subset [-1, 1]$ and $r_0$ is analytic such that $r_0(0) = 1$.

Remark 4.1. In fact, $r_0(u) = 1/\hat{\omega}(u)$ for $\hat{\omega}(u) = \int_{-1}^1 e^{-ut} \omega(t) \, dt$. Therefore $\frac{d}{du} r_0(u)$ and $\frac{d^2}{du^2} r_0(u)$ are continuous functions, and for later use, we set $\gamma_1 := \frac{d}{du} r_0(0), \gamma_2 := \frac{d^2}{du^2} r_0(0)$.

Since it is short, for the reader’s convenience we include the proof of (4.1) (as in the proof of [BMT, Proposition 4.1]).
Proof. Let \( \omega \) be an integrable function supported on \([-1, 1]\) such that \( \int_{-1}^{1} \omega(t) \, dt = 1 \), and set \( \hat{\omega}(u) = \int_{-1}^{1} e^{-ut} \omega(t) \, dt \). Note that \( \hat{\omega}(u) \) is analytic and \( \hat{\omega}(0) = 1 \). Since \( \tau \geq h \geq 1 \) (see the assumption on \( h \) in Sect. 2.2) and \( \operatorname{supp} \omega \subset [-1, 1] \),

\[
\int_{0}^{\infty} \omega(t - \tau) e^{-ut} dt = e^{-u\tau} \int_{-\tau}^{\infty} \omega(t) e^{-ut} \, dt = e^{-u\tau} \hat{\omega}(u).
\]

Hence,

\[
\int_{0}^{\infty} R(\omega(t - \tau)v) e^{-ut} \, dt = R\left( \int_{0}^{\infty} \omega(t - \tau) ve^{-ut} \, dt \right) = \hat{\omega}(u) \hat{R}(u)v.
\]

Formula (4.1) follows with \( r_0(u) = 1/\hat{\omega}(u) \), so \( r_0(0) = 1 \). \( \square \)

For most results we require that

(H2) There exists a function \( \omega \) satisfying (4.1) and \( C_\omega > 0 \) such that

(i) for any \( t \in \mathbb{R}_+ \) and for all \( v \in C^\alpha, h \in B \), we have \( \omega(t - \tau)h \in B_w \) and

\[
\langle \omega(t - \tau)v, h \rangle \leq C_\omega \| v \|_{C^\alpha} \| h \|_{B_w} \mu_\phi(\omega(t - \tau));
\]

(ii) for all \( T > 0 \),

\[
\int_{T}^{\infty} \| M(t) \|_{B \to B_w} \, dt \leq C_\omega \mu_\phi(\tau > T).
\]

Further, we assume the usual Doeblin-Fortet inequality:

(H3) There exist \( \sigma_0 > 1 \) and \( C_0, C_1 > 0 \) such that for all \( h \in B \), for all \( u > 0 \),

\[
\| \hat{R}(u)^n h \|_{B_w} \leq C_1 e^{-un} \| h \|_{B_w}, \quad \| \hat{R}(u)^n h \|_B \leq C_0 e^{-un} \sigma_0^{-n} \| h \|_B + C_1 \| h \|_{B_w}.
\]

4.4. Refined assumptions on \( \tau \). For the purpose of obtaining limit laws for \( F \) (and in the end \( f_t \)) we assume that

(H4) One of the following holds as \( t \to \infty \),

(i) \( \mu_\phi(\tau > t) = \ell(t)t^{-\beta} \), for some slowly varying function \( \ell \) and \( \beta \in (1, 2] \).

When \( \beta = 2 \), we assume \( \tau \notin L^2(\mu_\phi) \) and \( \ell \) is such that the function \( \tilde{\ell}(t) = \int_{t}^{\infty} \ell(x) \, dx \) is unbounded and slowly varying.

(ii) \( \tau \in L^2(\mu_\phi) \). We do not assume\(^3\) \( \tau \in B \), but require that for any \( h \in B \) and \( \kappa = 1, 2 \), \( R(\tau^\kappa h) \in B \).

\(^3\) In our example, \( \tau \) is only piecewise \( C^1(Y) \).
5. Limit Laws for \((\tau, F)\)

In this section we obtain limit theorems for the Birkhoff sum \(\tau_n = \sum_{j=0}^{n-1} \tau \circ F^j\). Under the abstract assumptions formulated in Sect. 4, we obtain the asymptotics of the leading eigenvalue of \(\hat{R}(u)\) (as in Sects. 5.1 and 5.2 below). In turn, as clarified in Sect. 5.3, the asymptotics of this (family of) eigenvalues give the asymptotics of the Laplace transform \(E_{\mu_\phi}(e^{-ut}\tau_n)\), for suitable normalising sequences \(b_n\), proving the claimed limit theorems. Our result reads as follows.

**Proposition 5.1.** Assume (H1) and (H2). The following hold as \(n \to \infty\), w.r.t. any probability measure \(\nu\) such that \(\nu \ll \mu_\phi\).

(i) Assume (H4)(i). When \(\beta < 2\), set \(b_n\) such that \(\frac{n\ell(b_n)}{b_n^\beta} \to 1\). Then \(\frac{1}{b_n} (\tau_n - \frac{\tau^*}{\nu(Y)}) \to^d G_\beta\), where \(G_\beta\) is a stable law of index \(\beta\).

When \(\beta = 2\), set \(b_n\) such that \(\frac{n\ell(b_n)}{b_n^\beta} \to c > 0\). Then \(\frac{1}{b_n} (\tau_n - \frac{\tau^*}{\nu(Y)}) \to^d N(0, c)\).

(ii) Assume (H4)(ii) and \(\tau = \tau^* \neq h - h \circ F\) for any \(h \in B\). Then there exists \(\sigma \neq 0\) such that \(\frac{1}{\sqrt{n}} (\tau_n - \frac{\tau^*}{\nu(Y)}) \to^d N(0, \sigma^2)\).

Note here that the slowly varying function \(\ell\) from the general theory later on reduces to \(\ell(n) = C^*\), because the tail estimates (2.3) have this form.

**Remark 5.2.** The above result holds for all piecewise \(C^1(Y)\) observables \(v\) in the space \(B_0(Y)\) defined in “Appendix A.3”. For item (i), we need to assume that \(v\) is in the domain of a stable law with index \(\beta \in (1, 2]\) with \(v \notin L^2(\mu_\phi)\) and adjusted \(C^* = C^*(v)\), while for item (ii) we assume \(v \in L^2(\mu_\phi)\) and a non-coboundary condition precisely formulated in Proposition 6.1 (ii).

The rest of this section is devoted to the proof of the above result.

### 5.1. Family of eigenvalues for \(\hat{R}(u)\)

By Eq. (4.1), Remark 4.1 and (H2)v(ii), \(\hat{R}(u)\) is an analytic family of bounded linear operators on \(B_w\) for \(u > 0\) and this family can be continuously extended as \(u \to 0\). As in Remark 4.1, \(\lim_{u \to 0} \frac{d}{du} r_0(u), \frac{d^2}{du^2} r_0(u)\) exist and we let \(\gamma_1 := \frac{d}{du} r_0(0), \gamma_2 := \frac{d^2}{du^2} r_0(0)\).

**Lemma 5.3.** Assume (H2). Then

\[
\|\hat{R}(u) - \hat{R}(0)\|_{B \to B_w} \ll u + \mu_\phi(\tau > 1/u) =: q(u).
\]

**Proof.** Using (4.1), we write

\[
\hat{R}(u) = (r_0(u) - 1) \int_0^\infty M(t) e^{-ut} dt + r_0(0) \int_0^\infty M(t) (e^{-ut} - 1) dt + r_0(0) \int_0^\infty M(t) dt
\]

\[
= (r_0(u) - 1) \int_0^\infty M(t) e^{-ut} dt + \int_0^\infty M(t) (e^{-ut} - 1) dt + \hat{R}(0).
\]

Since \(|(r_0(u) - 1| \leq u |\gamma_1| \ll u\), we have that as \(u \to 0\),
Rearranging, given the continuity estimate in Lemma 5.3, we can apply [KL99, Remark 5] (an improved version of [KL99, Corollary 1] under less general assumptions). Assumption here corresponds to [KL99, Hypotheses 2, 3] and the estimate in Lemma 5.3 (H3) corresponds to [KL99, Hypothesis 5]. The extra assumptions of [KL99, Remark 5] are satisfied in the present setup, since by (H3) \( t^{-\hat{\phi}(\tau > 1/u)} \) is an eigenvalue for \( \hat{R}(u) \), \( \hat{R} \) is a family of rank one projectors and we write \( P(u) = \mu_\phi(u) \otimes v(u) \), normalising such that \( \mu_\phi(u)(v(u)) = 1 \), where \( \mu_\phi(0) \) is the invariant measure and \( v(0) = 1 \in \mathcal{B} \). Equivalently, we normalise such that \( \langle v(u), 1 \rangle = 1 \) and write

\[
\hat{R}(u) = \lambda(u) P(u) + Q(u), \quad \|Q(u)^n\|_B \leq C\sigma^n_0.
\]

for all \( n \in \mathbb{N} \), some fixed \( C > 0 \) and some \( \sigma_0 < 1 \). Here, \( P(u) \) is a family of rank one projectors and we write \( P(u) = \mu_\phi(u) \otimes v(u) \), normalising such that \( \mu_\phi(u)(v(u)) = 1 \), where \( \mu_\phi(0) \) is the invariant measure and \( v(0) = 1 \in \mathcal{B} \). Equivalently, we normalise such that \( \langle v(u), 1 \rangle = 1 \) and write

\[
\lambda(u) = \langle \hat{R}(u)v(u), 1 \rangle.
\]

The result below gives the continuity of the families \( P(u) \) and \( v(u) \) (in \( \mathcal{B}_w \)).

**Lemma 5.4.** Assume (H1), (H2) and (H3). Let \( q(u) \) be as defined in Lemma 5.3. Then there exist \( 0 < \delta_1 \leq \delta_0 \) and \( C > 0 \) such that

\[
\|P(u) - P(0)\|_{\mathcal{B}_w} \leq C q(u) |\log(q(u))|
\]

for all \( 0 \leq u < \delta_1 \). The same continuity estimate holds for \( v(u) \) (viewed as an element of \( \mathcal{B}_w \)).

**Proof.** Given the continuity estimate in Lemma 5.3, we can apply [KL99, Remark 5] (an improved version of [KL99, Corollary 1] under less general assumptions). Assumption (H3) here corresponds to [KL99, Hypotheses 2, 3] and the estimate in Lemma 5.3 corresponds to [KL99, Hypothesis 5]. The extra assumptions of [KL99, Remark 5] are satisfied in the present setup, since by (H3), \( \hat{R}(u) \) is a family of \( \|\cdot\|_B \) contractions. Going from \( P(u) \) to \( v(u) \) is a standard step (see, for instance, [LT16, Proof of Lemma 3.5]).
Since \( \lambda(0) = 1 \) is a simple eigenvalue (by (H1)), Lemma 5.4 ensures that \( \lambda(u) \) is a family of simple eigenvalues (see [KL99, Remark 4]). The next result gives precise information on the asymptotic and continuity properties of \( \lambda(u) \), \( u \to 0 \) (a version of the results in [AD01a]) in the present abstract framework.

**Lemma 5.5.** Assume (H1) and (H2). Let \( q(u) \) be as defined in Lemma 5.3. Set \( \Pi(u) = \mu_\bar{\phi}(1 - e^{-ut}) \). Then as \( u \to 0 \),

\[
1 - \lambda(u) = \Pi(u) \left( 1 + O(q(u) | \log(q(u))|) \right).
\]

**Proof.** By (5.3), \( \lambda(u)v(u) = \hat{R}(u)v(u), u \in [0, \delta_0] \) with \( \lambda(0) = 1 \) and \( v(0) = \mu_\bar{\phi} \). Then

\[
\lambda(u) = \langle \hat{R}(u)v(u), 1 \rangle = \mu_\bar{\phi}(e^{-ut}) + \langle \hat{R}(u) - \hat{R}(0)(v(u) - v(0)), 1 \rangle.
\]

because \( \langle v(u), 1 \rangle = 1 \). Since (H2) holds (so, (4.1) holds),

\[
\lambda(u) = \mu_\bar{\phi}(e^{-ut}) + V(u) := \mu_\bar{\phi}(e^{-ut}) + \int_0^\infty (e^{-ut} - 1) \langle \omega(t - \tau)[v(u) - v(0)], 1 \rangle d\tau + (r_0(u) - 1) \int_0^\infty e^{-ut} \langle \omega(t - \tau)[v(u) - v(0)], 1 \rangle d\tau.
\]

Thus, \( 1 - \lambda(u) = \Pi(u) - V(u) \). By (H2)(i),

\[
\langle \omega(t - \tau)[v(u) - v(0)], 1 \rangle \leq C \|v(u) - v(0)\|_{B_w} \| \mu_\bar{\phi}(\omega(t - \tau)) \|
\]

Recalling that \( \text{supp} \omega \subset [-1, 1] \), for all \( u \in [0, \delta_0) \) and some \( C_1 > 0 \),

\[
\left| \int_0^\infty e^{-ut} \langle \omega(t - \tau)[v(u) - v(0)], 1 \rangle d\tau \right| \leq C \|v(u) - v(0)\|_{B_w} \left| \int_0^\infty e^{-ut} \int_Y \omega(t - \tau) d\mu_\bar{\phi} d\tau \right| \\
\leq C \|v(u) - v(0)\|_{B_w} \left| \int_Y \int_{t - 1}^{t + 1} e^{-ut} \omega(t - \tau) d\tau d\mu_\bar{\phi} \right| \\
\leq C \|v(u) - v(0)\|_{B_w} \left| \int_Y e^{-ut} \int_{-1}^{1} \omega(t) e^{ut} dt d\mu_\bar{\phi} \right| \\
\leq C_1 \|v(u) - v(0)\|_{B_w} \int_Y e^{-ut} d\mu_\bar{\phi} = C_1 \|v(u) - v(0)\|_{B_w} (\Pi(u) + 1).
\]

In the previous to last inequality, we have used that \( \left| \int_{-1}^{1} \omega(t) e^{ut} dt \right| \ll 1 \) for \( u \in [0, \delta_0) \). By a similar argument,

\[
\left| \int_0^\infty (e^{-ut} - 1) \langle \omega(t - \tau)[v(u) - v(0)], 1 \rangle d\tau \right| \leq C_1 \|v(u) - v(0)\|_{B_w} \Pi(u).
\]

The previous two displayed equations imply that for \( u \in [0, \delta_0) \),

\[
|V(u)| \leq C_1 \|v(u) - v(0)\|_{B_w} |r_0(u) - 1| (\Pi(u) + 1) + C_1 \|v(u) - v(0)\|_{B_w} \Pi(u) \\
\leq C_1 \|v(u) - v(0)\|_{B_w} \Pi(u).
\]

By Lemma 5.4, \( \|v(u) - v(0)\|_{B_w} = O(q(u) | \log(q(u))|) \). Hence \( V(u) = O(\Pi(u)q(u) | \log(q(u))|) \).

\[ \square \]
A first consequence of the above result is

**Corollary 5.6.** Assume (H1) and (H2). The following hold as \( u \to 0 \).

(i) If (H4)(i) holds with \( \beta < 2 \), then \( 1 - \lambda(u) = \tau^* u + u^\beta \ell(1/u)(1 + o(1)) \).

(ii) If (H4)(i) holds with \( \beta = 2 \), then \( 1 - \lambda(u) = \tau^* u + u^2 L(1/u)(1 + o(1)) \), where \( L(t) = \frac{1}{2} \tilde{\ell}(t) \).

**Proof.** Under (H4)(i) with \( \beta < 2 \), \( \Pi(u) = \tau^* u + u^\beta \ell(1/u)(1 + o(1)) \); we refer to, for instance, [F66, Ch. XIII] and [AD01b]. This together with Lemma 5.5 (with \( q(u) \sim u \)) ensures that \( 1 - \lambda(u) = \tau^* u + u^\beta \ell(1/u) + O(u^2 \log(1/u)) + O(u^\beta + 1 \ell(1/u)) \). Item (i) follows.

Under (H4)(i) with \( \beta = 2 \), it follows from [AD01b, Theorem 3.1 and Corollary 3.7] that \( \Pi(u) = \tau^* u + u^2 L(1/u)(1 + o(1)) \), where \( L(t) \sim \ell(t) \log(1/t) \) with \( \ell(t) = \int_1^t \ell(x)/x \) as in (H4)(i) for \( \beta = 2 \). The estimate for \( \Pi(u) \) together with Lemma 5.5 (with \( q(u) \sim u \)) implies that \( 1 - \lambda(u) = \tau^* u + u^2 L(1/u) + O(u \log(1/u) \Pi(u)) \).

In the case of (H4)(i) with \( \beta = 2 \) and \( \ell(1/u) \to \infty \) as \( u \to 0 \), we have \( \log(1/u) = o(L(1/u)) \). As a consequence, \( u \log(1/u) \Pi(u) = O(u^2 \log(1/u)) = o(u^2 L(1/u)) \) and the conclusion follows. In the general case (which allows \( \ell \) to be asymptotically constant), for fixed small \( \delta > 0 \) and \( \epsilon > 0 \), we write

\[
u \log(1/u) \Pi(u) = u \log(1/u) \left( \Pi(u) - \int_{\tau \leq \delta/u} (e^{-u^{2+\epsilon} \tau^{2+\epsilon}/2} - 1) d\mu_\phi \right) + u \log(1/u) \int_{\tau \leq \delta/u} (e^{-u^{2+\epsilon} \tau^{2+\epsilon}/2} - 1) d\mu_\phi = u \log(1/u) (I_1(u) + I_2(u)).\]

First,

\[
u \log(1/u) |I_2(u)| \ll u \log(1/u) u^{2+\epsilon} \int_{\tau \leq \delta/u} \tau^{2+\epsilon} d\mu_\phi \leq (log(1/u)) u^{3+\epsilon} u^{-2\epsilon} \delta^2 \int_{\tau \leq \delta/u} \tau^{2-\epsilon} d\mu_\phi = o(u^2 L(1/u)).\]

Next, compute that

\[
I_1(u) = \int_{\tau \leq \delta/u} (e^{-u\tau} - e^{-u^{2+\epsilon}\tau^{2+\epsilon}/2}) d\mu_\phi + \int_{\tau > \delta/u} (e^{-u\tau} - 1) d\mu_\phi
\]

\[
= \int_{\tau \leq \delta/u} (e^{-u\tau} - e^{-u^{2+\epsilon}\tau^{2+\epsilon}/2}) d\mu_\phi + O(\mu_\phi(\tau > \delta/u))
\]

\[
= \int_{\tau \leq \delta/u} e^{-u\tau} (1 - e^{-u^{1+\epsilon}\tau^{1+\epsilon}}) d\mu_\phi + O(u^2 \ell(\delta/u)).
\]

Let \( G(x) = \mu_\phi(\tau < x) \) and compute that

\[
\int_{\tau \leq \delta/u} e^{-u\tau} (1 - e^{-u^{1+\epsilon}\tau^{1+\epsilon}}) d\mu_\phi \ll u^{1+\epsilon} \int_{\tau \leq \delta/u} \tau^{1+\epsilon} e^{-u\tau} d\mu_\phi
\]

\[
\ll u^{1+\epsilon} \int_0^\infty x^{1+\epsilon} e^{-ux} dG(x) = -u^{1+\epsilon} \int_0^\infty x^{1+\epsilon} e^{-ux} d(1 - G(x))
\]

\[
= u^{2+\epsilon} \int_0^\infty x^{-\epsilon} (1 - G(x)) e^{-ux} dx + u^{1+\epsilon} \int_0^\infty x^{-\epsilon} (1 - G(x)) e^{-ux} dx \ll u^{1+\epsilon}.
\]
Altogether, \( I_1(u) \ll u^{1+\varepsilon} \). Hence, \( u \log(1/u)|I_1(u)| = o(u^2 L(1/u)) \). This together with the estimate for \( u \log(1/u)|I_2(u) \) implies that \( u \log(1/u)\Pi(u) = o(u^2 L(1/u)) \) and item (ii) follows. \( \square \)

5.2. Estimates required for the CLT under (H4)(ii). For the CLT case we need the following

**Proposition 5.7.** Assume (H1), (H2) and (H4)(ii). Suppose that \( \tau \neq h \circ F - h \), for any \( h \in \mathcal{B} \). Then there exists \( \sigma \neq 0 \) such that \( 1 - \lambda(u) = \tau^* u + \frac{u^2}{2}(1 + o(1)) \).

We need to ensure that under the assumptions of Proposition 5.7, which do not require that \( \tau \in \mathcal{B} \), there exists the required \( \sigma \neq 0 \). The argument goes by and large as [G04, Proof of Theorem 3.7] (which works with a different Banach space) with the exception of estimating the second derivative of the eigenvalue \( \lambda \) defined below. The argument in [G04, Proof of Theorem 3.7] for estimating such a derivative does not directly apply to our setup due to: (i) the two Banach spaces \( \mathcal{B}, \mathcal{B}_w \) at our disposal are not embedded in \( L^p, p > 1 \); (ii) the presence of \( \log q(u) \) in Lemma 5.4. Our estimates below rely heavily on (H2) and (H4)(ii).

As usual, we can can reduce the proof to the case of mean zero observables. Let \( \tilde{\tau} = \tau - \tau^* \). We recall that under (H4)(ii), \( R(\tau h) \in \mathcal{B} \), for every in \( h \in \mathcal{B} \) and the same holds for \( \tilde{\tau} \). By H1(v), \( (I - R) \) is invertible on the space of functions inside \( \mathcal{B} \) of zero integral. Thus, as in [G04, Proof of Theorem 3.7], we can set

\[
\chi := (I - R)^{-1} R\tilde{\tau} \in \mathcal{B}.
\]  

Define \( \tilde{R}(u) = R(e^{-u\tilde{\tau}}) \). Clearly, \( \tilde{R}(u) \) has the same continuity properties as \( \hat{R}(u) \). Let \( \tilde{\lambda}(u) \) be the associated family of eigenvalues. Recall that \( \lambda(u) \) is the family of eigenvalues associated with \( \hat{R}(u) \). Hence, \( \lambda(u) = e^{u\tau^*}\tilde{\lambda}(u) \). As in the previous sections, let \( v(u) \) be the family of associated eigenvectors normalised such that \( \langle v(u), 1 \rangle = 1 \). The next three results are technical tools required in the proof of Proposition 5.7; the third, which has a longer proof, is postponed to Sect. 5.2.1.

**Lemma 5.8.** Suppose that (H1)–(H3) and (H4)(ii) hold, and recall \( \tilde{\tau} = \tau - \tau^* \). Then

\[
\frac{d^2}{du^2} \tilde{\lambda}(u) = - \int_Y \tilde{\tau}^2 d\mu_\phi - 2 \left( \frac{d}{du} \tilde{R}(u) \frac{d}{du} v(u), 1 \right) + T(u),
\]

where \( T(u) \to 0, \) as \( u \to 0 \).

**Proof.** Set \( \tilde{\Pi}(u) = \mu_\phi(1 - e^{-u\tilde{\tau}}) \). By the calculation used in the proof of Lemma 5.5, \( 1 - \tilde{\lambda}(u) = \tilde{\Pi}(u) - \langle (\tilde{R}(u) - \bar{R}(0))(\bar{v}(u) - v(0)), 1 \rangle \). Differentiating twice,

\[
\frac{d^2}{du^2} \tilde{\lambda}(u) - \frac{d^2}{du^2} \tilde{\Pi}(u) = \left( \frac{d^2}{du^2} \tilde{R}(u)(v(u) - v(0), 1) + 2 \left( \frac{d}{du} \tilde{R}(u) \frac{d}{du} v(u), 1 \right) \right) + \left( (\tilde{R}(u) - \bar{R}(0)) \frac{d^2}{du^2} v(u), 1 \right).
\]

Under (H2)(i) and (H4)(ii), arguments similar to the ones used in Lemma 5.5 imply that as \( u \to 0 \),
\[
\left\| \left( \frac{d^2}{du^2} \tilde{R}(u) - \frac{d}{du} \right) v(u), 1 \right\| \leq \frac{d^2}{du^2} v(u) \right\|_{L^2} \int_0^\infty \left[ e^{-ut} - 1 \right] \mu_{\tilde{\phi}}(\omega(t - \tilde{r})) \, dt \\
+ |r_0(u) - 1| \left\| \frac{d^2}{du^2} v(u) \right\|_{L^2} \int_0^\infty e^{-ut} \mu_{\tilde{\phi}}(\omega(t - \tilde{r})) \, dt \ll u \log(1/u) = o(1).}
\]

(H4)(ii) and (5.4) imply that \(|\left( \frac{d^2}{du^2} \tilde{R}(u) (v(u) - v(0), 1) \right| \ll u \log(1/u) = o(1). Finally, \(\frac{d^2}{du^2} \tilde{R}(u) = -\int \tilde{r}^2 \mu_{\tilde{\phi}}(1 + o(1))\). The conclusion follows by putting the above estimates together. \(\square\)

**Lemma 5.9.** Assume the setup of Proposition 5.7. Then

\[
\left\{ \frac{d}{du} \tilde{R}(u), \frac{d}{du} v(u), 1 \right\} = -\int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}} + D(u),
\]

where \(D(u) = o(1)\) as \(u \to 0\), and \(\chi\) is defined as in (5.4).

**Proof of Proposition 5.7.** By Lemmas 5.8 and 5.9,

\[
\frac{d^2}{du^2} \tilde{\lambda}(u) = -\int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}} - 2\int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}} + \tilde{T}(u), (5.5)
\]

where \(\tilde{T}(u) \to 0\), as \(u \to 0\). Hence, \(-\frac{d^2}{du^2} \tilde{\lambda}(u)|_{u=0} = \int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}} + 2\int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}}\) and we can set \(\tilde{\sigma}^2 = \int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}} + 2\int \tilde{r} \tilde{\chi} \, d\mu_{\tilde{\phi}}\). From here on the proof goes word for word as [G04, Proof of Theorem 3.7], which shows that given the previous formula for \(\sigma\), the only possibility for \(\sigma = 0\) is when \(\tilde{r} = h - h \circ F\), for some density \(h \in B\). This is ruled out by assumption.

To conclude recall that \(\lambda(u) = e^{u\tilde{r}^*} \tilde{\lambda}(u)\). By (5.5), \(1 - \tilde{\lambda}(u) = \frac{\tilde{\sigma}^2}{2} u^2 (1 + o(1))\), as required. \(\square\)

5.2.1. **Proof of Lemma 5.9**

**Proof of Lemma 5.9.** Let \(W(u) := \frac{d}{du} \tilde{R}(u)\). Since \(\tilde{R}(u) = R(e^{-u\tilde{r}})\), we have that for any \(h \in B\),

\[
W(0)h := \left. \frac{d}{du} \tilde{R}(u) \right|_{u=0} h = -R(\tilde{r}h). (5.6)
\]

By (H4)(ii), \(W(0)h \in B\). Recall that \(P(u)\) is the eigenprojection for \(\tilde{R}(u)\), so for \(\tilde{R}(u)\) as well. For \(\delta\) small enough (independent of \(u\)), we can write

\[
P(u) = \int_{|\xi| - 1 = \delta} (\xi I - \tilde{R}(u))^{-1} \, d\xi.
\]

Recall that \(v(u) = \frac{P(u)}{m_{\tilde{\phi}}(u)1} = \frac{P(u)1}{m_{\tilde{\phi}}(u)1}\); in particular, \(\mu_{\tilde{\phi}}(u)1 = (P(u)1, 1)\). Compute

\[
\frac{d}{du} v(u) = \frac{P(u)}{\mu_{\tilde{\phi}}(u)1} - \frac{P(u)1}{(\mu_{\tilde{\phi}}(u)1)^2} \frac{d}{du} \mu_{\tilde{\phi}}(u)1. (5.7)
\]

Also, compute that by (5.6)
\[
\frac{d}{du} P(u) = \int_{|\xi - 1| = \delta} (\xi I - \tilde{R}(u))^{-1} W(u)(\xi I - \tilde{R}(u))^{-1} d\xi \\
= \int_{|\xi - 1| = \delta} (\xi I - R)^{-1} W(0)(\xi I - R)^{-1} d\xi + Z_0(u) \\
= -\int_{|\xi - 1| = \delta} (\xi I - R)^{-1} R\tilde{r}(\xi I - R)^{-1} d\xi + Z_0(u),
\]

where the first term is well defined in \(B\) by \((H4)(ii)\) and

\[
\|Z_0(u)\|_B \ll \left\| \int_{|\xi - 1| = \delta} (\xi I - R)^{-1} \left(W(u) - W(0)\right)(\xi I - R)^{-1} d\xi \right\|_B \\
+ \left\| \int_{|\xi - 1| = \delta} \left((\xi I - R(u))^{-1} - (\xi I - R)^{-1}\right) W(u)(\xi I - R)^{-1} d\xi \right\|_B \\
+ \left\| \int_{|\xi - 1| = \delta} (\xi I - R)^{-1} W(u) \left((\xi I - R(u))^{-1} - (\xi I - R)^{-1}\right) d\xi \right\|_B.
\]

Again using \((H4)(ii)\), \(\frac{d^2}{du^2} \tilde{R}(u)\) is bounded in \(\|\cdot\|_B\); so, \(\|W(u) - W(0)\|_B \ll u\). Hence, each one of three terms of the previous displayed equation contains an \(O(u)\) factor. By the argument recalled in the proof of Lemma 5.4, for any \(\xi\) such that \(|\xi - 1| = \delta\), the integrand of each one of these three terms is \(o(1)\). Altogether, \(\|Z_0(u)\|_B = o(1)\). Also, by (5.8) and Lemma 5.10 below,

\[
\frac{d}{du} P(u) = -\chi - \xi_0 \int_Y \chi \, d\mu_{\tilde{\phi}} + Z_0(u),
\]

for some \(\xi_0 \in \mathbb{C}\) and \(\chi = (I - R)^{-1} R\tilde{r}\) as in (5.4). Plugging (5.9) into (5.7),

\[
\frac{d}{du} v(u) = \frac{1}{\mu_{\tilde{\phi}}(0)1} \left(-\chi - \xi_0 \int_Y \chi \, d\mu_{\tilde{\phi}}\right) \\
= \frac{P(0)1}{(\mu_{\tilde{\phi}}(0)1)^2} \left(-\chi - \xi_0 \int_Y \chi \, d\mu_{\tilde{\phi}}, 1\right) + Z_1(u) + Z_0(u) \\
= -\chi + \tilde{\xi} \int_Y \chi \, d\mu_{\tilde{\phi}} + Z_1(u) + Z_0(u),
\]

where \(\tilde{\xi}\) is linear combination of \(\xi_0\) and

\[
\|Z_1(u)\|_{B_w} \ll \frac{|\mu_{\tilde{\phi}}(u)1 - \mu_{\tilde{\phi}}(0)1|}{m_{\tilde{\phi}}(u)1} + \frac{\|P(u)1 - P(0)1\|_{B_w}}{(m_{\tilde{\phi}}(u)1)^2} + \frac{1}{\mu_{\tilde{\phi}}(u)1} - \frac{1}{\mu_{\tilde{\phi}}(0)1} \\
+ \left|\frac{1}{(\mu_{\tilde{\phi}}(u)1)^2} - \frac{1}{(\mu_{\tilde{\phi}}(0)1)^2}\right|.
\]

By Lemma 5.4, \(\|P(u)1 - P(0)1\|_{B_w} \ll u \log(1/u)\) and as a consequence, \(|\mu_{\tilde{\phi}}(u)1 - \mu_{\tilde{\phi}}(0)1| \ll u \log(1/u)\). Thus, \(\|Z_1(u)\|_{B_w} = o(1)\). Recalling that \(\|Z_0(u)\|_{B_w} = o(1)\), we have

\[
\frac{d}{du} v(u) = -\chi + \tilde{\xi} \int_Y \chi \, d\mu_{\tilde{\phi}} + Z(u),
\]
where \( \|Z(u)\|_{B^w} = o(1) \). Using this expression for \( \frac{d}{du} v(u) \), we obtain

\[
\left\langle \frac{d}{du} \tilde{R}(u) \frac{d}{du} v(u), 1 \right\rangle = - \left( R \tilde{\tau} \frac{d}{du} v(u), 1 \right) + \left( (W(u) - W(0)) \frac{d}{du} v(u), 1 \right)
\]

\[
= - \int_Y R \tilde{\tau} \chi d\mu_\phi + \tilde{\xi} \int_Y \chi d\mu_\phi + \left( RZ(u), 1 \right) + \left( (W(u) - W(0)) \frac{d}{du} v(u), 1 \right)
\]

where we have used \( \int \tilde{\tau} d\mu_\phi = 0 \). Finally, using (H2), we compute that

\[
|\langle RZ(u), 1 \rangle| \ll \|Z(u)\|_{B^w} \int_0^\infty \int_Y \omega(t - \tilde{\tau}) d\mu_\phi dt \ll \|Z(u)\|_{B^w} = o(1).
\]

Similarly, \(|\langle (W(u) - W(0) w(u), 1) \rangle| = o(1) \), since we already know that \( \|W(u) - W(0)\|_{B^w} = o(1) \). Thus,

\[
\left\langle \frac{d}{du} \tilde{R}(u) \frac{d}{du} v(u), 1 \right\rangle = - \int_Y \tilde{\tau} \chi d\mu_\phi + o(1),
\]

ending the proof. \( \square \)

**Lemma 5.10.** Assume the setup and notation of Lemma 5.9. Then there exists \( \xi_0 \in \mathbb{C} \) with such that

\[
\int_{|\xi - 1| = \delta} (\xi I - R)^{-1} R \overline{\tau} (\xi I - R)^{-1} d\xi = \chi + \xi_0 \int_Y \chi d\mu_\phi.
\]

**Proof.** We note that for each \( \xi \) such that \( |\xi - 1| = \delta \), \( R \overline{\tau} (\xi I - R)^{-1} 1 \) is well defined in \( B \) by (H4)(ii) and that \( \int_{|\xi - 1| = \delta} R \overline{\tau} (\xi I - R)^{-1} 1 d\xi = 0 \). Hence, \( \int_{|\xi - 1| = \delta} (I - R)^{-1} R \overline{\tau} (\xi I - R)^{-1} 1 d\xi \in B \).

By the first resolvent identity and the Mean Value Theorem,

\[
\int_{|\xi - 1| = \delta} (\xi I - R)^{-1} R \overline{\tau} (\xi I - R)^{-1} 1 d\xi
\]

\[
= \int_{|\xi - 1| = \delta} (I - R)^{-1} R \overline{\tau} (\xi I - R)^{-1} 1 d\xi
\]

\[
+ \int_{|\xi - 1| = \delta} ((\xi I - R)^{-1} - (I - R)^{-1}) R \overline{\tau} (\xi I - R)^{-1} 1 d\xi
\]

\[
= \chi P(0) 1 + \int_{|\xi - 1| = \delta} (1 - \xi)(\xi I - R)^{-1} \chi (\xi I - R)^{-1} 1 d\xi
\]

\[
= \chi + \xi_1 \int_{|\xi - 1| = \delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} 1 d\xi,
\]

where \( \xi_1 \) is a complex constant with \( 0 < |\xi_1| \leq \delta \).

Write \( (\xi I - R)^{-1} - I = -((\xi I - R)^{-1}((\xi - 1)I - R)) \). The Mean Value Theorem gives
\[ \int_{|\xi-1|=\delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} d\xi = \int_{|\xi-1|=\delta} (\xi I - R)^{-1} a \left( I + (\xi I - R)^{-1} - I \right) d\xi \]
\[ = \int_{|\xi-1|=\delta} (\xi I - R)^{-1} d\xi - \int_{|\xi-1|=\delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} ((\xi - 1) I - R) d\xi \]
\[ = P(0)\chi - \int_{|\xi-1|=\delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} (\xi - 2) d\xi \]
\[ = \int_Y \chi d\mu_{\tilde{\phi}} - (\xi_2 - 2) \int_{|\xi-1|=\delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} 1 d\xi, \]

\text{for some } \xi_2 \in \mathbb{C} \text{ with } |\xi_2 - 1| \leq \delta. \text{ Thus,}

\[ (\xi_2 - 1) \int_{|\xi-1|=\delta} (\xi I - R)^{-1} \chi (\xi I - R)^{-1} 1 d\xi = \int_Y \chi d\mu_{\tilde{\phi}}. \]

Since \( \int_Y \chi d\mu_{\tilde{\phi}} > 0 \), we have \( \xi_2 \neq 1 \). The conclusion follows with \( \xi_0 = \xi_1 (\xi_2 - 1)^{-1} \).

\[ \square \]

5.3. Proof of Proposition 5.1. We start with part (i), i.e., the stable and non standard Gaussian laws. Let \( \tau_n \) and \( b_n \) be as in Proposition 5.1. Using (5.2) and Corollary 5.6 (based on [AD01b]) we obtain that the Laplace transform \( \mathbb{E}_{\mu_{\tilde{\phi}}} (e^{-ub_n^{-1}T}) \) converges (as \( n \to \infty \)) to the Laplace transform of either the stable law or of the \( \mathcal{N}(0, 1) \) law. The conclusion w.r.t. \( \mu_{\tilde{\phi}} \) follows from the theory of Laplace transforms (as in [F66, Ch. XIII]). The conclusion w.r.t. \( \nu \) follows from [E04, Theorem 4].

For part (ii), i.e., the CLT, let \( \tau_n \) and \( b_n \) be as in Proposition 5.1 under (H4)(ii). Proposition 5.7 shows that the Laplace transform \( \mathbb{E}_{\mu_{\tilde{\phi}}} (e^{-ub_n^{-1}T}) \) converges (as \( n \to \infty \)) to the Laplace transform of \( \mathcal{N}(0, \sigma^2) \). The conclusion w.r.t. \( \mu_{\tilde{\phi}} \) follows from the theory of Laplace transforms (as in [F66, Ch. XIII]). The conclusion w.r.t. \( \nu \) follows from [E04, Theorem 4].

6. Limit Laws for the Flow \( f_t \)

The result below generalises Proposition 5.1 to the flow \( f_t \). Given an \( \alpha \)-Hölder observable \( g : \mathcal{M} \to \mathbb{R} \), define \( \tilde{g} : Y \to \mathbb{R} \) as in (3.2) and let \( g_T = \int_0^T g \circ f_t \, dt \).

**Proposition 6.1.** Assume (H1). Let \( g : \mathcal{M} \to \mathbb{R} \) and let \( g^* = \int_Y \tilde{g} \, d\mu_{\tilde{\phi}} \). Suppose that the twisted operator \( \tilde{R}_g(u) = R(e^{-u\tilde{g}}) \) satisfies (H2) (with \( \tau \) replaced by \( \tilde{g} \)). Then the following hold as \( T \to \infty \), w.r.t. \( \mu_{\tilde{\phi}} \) (or any probability measure \( \nu \ll \mu_{\tilde{\phi}} \)).

(i) Assume (H4)(i) and \( \mu_{\tilde{\phi}}(\tilde{g} > T) \sim \mu_{\tilde{\phi}}(\tau > T) \).

When \( \beta < 2 \), set \( b(T) \) such that \( T \ell(b(T))^{\beta} \to 1 \). Then \( \frac{1}{b(T)} (g_T - g^* \cdot T) \to^d G_\beta \), where \( G_\beta \) is a stable law of index \( \beta \).

When \( \beta = 2 \), set \( b(T) \) such that \( \frac{T \ell(b(T))}{b(T)^2} \to c > 0 \), then \( \frac{1}{b(T)} (g_T - g^* \cdot T) \to^d \mathcal{N}(0, c) \).

(ii) Suppose that (H4)(ii) holds. If \( \tilde{g} \notin \mathcal{B} \), we assume that \( R\tilde{g} \in \mathcal{B} \). We further assume that \( \tilde{g} \neq h - h \circ F \) with \( h \in \mathcal{B} \). Then there exists \( \sigma > 0 \) such that \( \frac{1}{\sqrt{T}} (g_T - g^* \cdot T) \to^d \mathcal{N}(0, \sigma^2) \).
Remark 6.2. The assumption \( \mu_{\phi}(g > T) \sim \mu_{\phi}(\tau > T) \) is satisfied for all \( g \) bounded above with \( \int_0^{h(x)} g \circ f_t(p) \, dt = c > 0 \) (where \( p \in \Sigma \) is the fixed point of the Poincaré section) and such that \( \int_0^{h(x)} g \circ f_t(q) \, dt \) is \( C^\alpha \) in \( q \) near \( p \). The proof of this is similar to [G04, Proof of Theorem 1.3] where the source of non-hyperbolicity was a neutral fixed point \( x_0 \) instead of a neutral periodic orbit \( \Gamma = \{ p \} \times \mathbb{T}^1 \). Therefore, we just need to replace \( g(x_0) \) in [G04, Proof of Theorem 1.3] by \( \int_0^{h(p)} g \circ f_t(p) \, dt \).

In Theorem 8.2 below, we consider potentials of the form \( \bar{g} = C' - C\tau^\kappa(1 + o(1)) \), \( \kappa \in (0, \beta) \) and obtain specific form of (i) and/or (ii) for different values of \( \kappa \).

Proof. We use that \( f_t : M \to M \) can be represented as a suspension flow \( F_t : \mathcal{Y}^\tau \to \mathcal{Y}^\tau \). Under the present assumptions, \( \bar{g} \) satisfies all the assumptions of Proposition 5.1 (with \( \tau \) replaced by \( \bar{\tau} \)).

Let \( \bar{g}_n = \sum_{j=0}^{n-1} \bar{g} \circ F^j \) and recall \( \tau_n = \sum_{j=0}^{n-1} \tau \circ F^j \). Proposition 5.1 (i) applies to \( \bar{\tau}_n \), the argument goes word for word as in the proof of Proposition 5.1 (i) for \( \bar{\tau}_n \). Under the present assumptions on \( \bar{g} \), item (ii) of Proposition 5.1 applies to \( \bar{g}_n \) with the argument used in the proof of Proposition 5.7 applying word for word with \( \bar{g} \) instead of \( \tau \).

Item (i) follows from this together with Lemma 6.3 below (correspondence between stable laws/non standard Gaussian for the base map \( F \) and suspension flow). Item (ii) follows in the same way using [MTo04, Theorem 1.3] instead of Lemma 6.3. \( \square \)

The next result is a version of [S06, Theorem 7] (generalising [MTo04, Theorem 1.3]) for suspension flows which holds in a very general setup; in particular, it is totally independent of method used to prove limit theorems for the base map.

Lemma 6.3. Assume \( \int_Y \bar{\tau} \, d\mu_{\phi} < \infty \) and let \( g \in L^q(\mu_{\phi}) \), for \( q > 1 \). Suppose that there exists a sequence \( b_n = n^{-\rho} \ell(n) \) for \( \rho \in (1, 2) \) and \( \ell \) a slowly varying function such that \( b_n^{-1} \left( \tau_n - n \int_Y \bar{\tau} \, d\mu_{\phi} \right) \) is tight on \( (Y, \mu_{\phi}) \). Then the following are equivalent:

(a) \( b_n^{-1} \bar{g}_n \) converges in distribution on \( (Y, \mu_{\phi}) \).
(b) \( b(T)^{-1} g_T \) converges in distribution on \( (Y^\tau, \mu_{\phi}) \), where \( b(T) = T^{-\rho} \ell(T) \).

Proof. The fact the (b) implies (a) is obvious. The implication from (a) to (b) is contained in the proofs of [MTo04, Theorem 1.3] for the standard CLT case and in [S06, Theorem 7] for the stable and nonstandard CLT. We sketch the argument for completeness.

Following [MTo04], let \( n[x, T] \) denote the largest integer such that \( \tau_n(x) = T \); that is,

\[ \tau_{n[x,T]}(x) \leq T \leq \tau_{n[x,T]+1}(x). \]

By the ergodic theorem, \( \lim_{T \to \infty} \frac{1}{T} \int_0^T \bar{g}_n(x, T) \, d\mu_{\phi} = \tau \), a.e. Hence, \( n[x, T] = \lfloor \frac{T}{\bar{\tau}} \rfloor (1 + o(1)) \), a.e. as \( T \to \infty \).

Recall that \( g : Y^\tau \to \mathbb{R} \) and define \( \bar{g}_T(y, u) = g_T(y) \). Recall \( \bar{g}(y) = \int_0^\tau(y) g(y, u) \, du \).

By assumption, \( b_n^{-1} \bar{g}_n \) converges in distribution on \( (Y, \mu_{\phi}) \). Hence, (as in [MTo04, Lemma 3.1]), \( b_n^{-1} \bar{g}_n \) converges in distribution on \( (Y^\tau, \mu_{\phi}^\tau) \); this is a consequence of [E04, Theorem 4].

In what follows we adopt the convention \( b_T = b(T) \). Write

\[ \frac{g_T}{b_T} = \frac{b(\bar{\tau} \bar{T})}{b_T} \left( \frac{\bar{g}(\bar{\tau} \bar{T})}{b(\bar{\tau} \bar{T})} \right) + \frac{1}{b(\bar{\tau} \bar{T})} \left( \frac{\bar{g}_n(x, T) - \bar{\mu}(\bar{\tau} \bar{T})}{\bar{b}(\bar{\tau} \bar{T})} + \left( \frac{\bar{g}_n(x, T)}{\bar{b}(\bar{\tau} \bar{T})} - \tau_{n[x,T]} \right) \circ F^{\tau_{n[x,T]}} \right). \]
Since $\ell$ is slowly varying, $\frac{b^{1+T_1}}{b^T} \to \bar{\tau}^\rho$. Since $g \in L^1(\mu_\phi^\gamma)$, [S06, Step 2 of the proof of Theorem 7] (a generalization of [MTo04, Lemma 3.4]) applies and thus, 
\[
\frac{1}{b^T} \left( \bar{g}_{n[x,T]} - g_{[T]} \right) \to_0 \text{d} \text{ on } (Y, \mu_\phi).
\]

Next, since $b^T \to \bar{\tau}$ is tight on $(Y, \mu_\phi)$, we have that $\tau \in L^{1/\rho}(\mu_\phi)$. By assumption, $g \in L^{q}(\mu_\phi^\gamma)$, for $q > 1$. Hence, the assumptions of [MTo04, Lemma 2.1] are satisfied with $a = p = 1/\rho$ and any $b := q > 1$ (with $a, b, p$ as there). By [MTo04, Lemma 2.1 (b)], $\frac{g^T}{b^T} \to \bar{g}_{n[x,T]} \to_0 \text{d} \text{ on } (Y^\tau, \mu_\phi^\gamma)$.

To conclude, note that $\bar{g}_{n[x,T]}(y, u) = g_{n[x,T]}(y)$. By [S06, Step 3 of the proof of Theorem 7], $\bar{g}_{n[x,T]} \to_0 \text{d} \text{ on } (Y, \mu_\phi)$, as required. 

\[ \square \]

7. Asymptotics of $\mathcal{P}(\phi + s\psi)$ for the Flow $f_t$

In this section and the next we shall assume that $F: Y \to Y$ is Markov, which allows us to express our results in terms of pressure. We will also assume that $P(\phi) = 0$ for all the potential functions $\phi$ involved. [S06, Theorem 8] gives a link between the shape of the pressure of a given discrete time finite measure dynamical system and an induced version (this was extended in [BTT18] to some infinite measure settings). Here we give a version of this result in the abstract setup of Sect. 4 along with suitable assumptions on a second potential $\psi$. Note that our assumptions are not directly comparable with those in [S06, Theorem 8].

Throughout this section, we let $\phi: \mathcal{M} \to \mathbb{R}$ and $\mu_\phi$ be as Sect. 4. In particular, we recall that $\tau^* = \int_Y \tau \text{d}\mu_\phi < \infty$ and assume that the conformal measure $m_\phi$ satisfies (H1). This ensures that $\mu_\phi$ is an equilibrium measure for $(F, \hat{\phi})$ and $\mu_\phi$ is an equilibrium measure for $(f_t, \phi)$. We consider the potential $\psi: \mathcal{M} \to \mathbb{R}$ and its induced version $\hat{\psi}$ on $Y$, we define the ‘doubly perturbed’ operator

$$
\hat{R}(u, s)v := R(e^{-u\tau}e^{s\hat{\psi}}v).
$$

Under (H5), we require the following extended version of (H3).

(H6) There exist $\sigma_1 > 1$, constants $C_0, C_1, \delta > 0$ such that for all $h \in \mathcal{B}$, for all $n \in \mathbb{N}$ and $u \geq 0, s \in [0, \delta)$,

$$
\Vert \hat{R}(u, s)^n h \Vert_{\mathcal{B}_w} \leq C_1 \Vert h \Vert_{\mathcal{B}_w}, \quad \Vert \hat{R}(u, s)^n h \Vert_{\mathcal{B}} \leq C_0 \sigma_1^{-n} \Vert h \Vert_{\mathcal{B}} + C_1 \Vert h \Vert_{\mathcal{B}_w}.
$$

To ensure that we can understand the pressure $\mathcal{P}(\hat{\phi} + s\hat{\psi})$ in terms of the eigenvalues of $\hat{R}(u, s)$, under (H1) (in particular, for $\alpha$ as in (H1)(i)) and (H5) we require that

(H7) There exist $\gamma \in (0, 1]$ (with $\gamma < 1$ when $\kappa > 1$) and $C_2, C_3, \delta > 0$ such that for all $u \geq 0, s \in (0, \delta)$, $h \in \mathcal{B}$ and every element $a$ of the (Markov) partition $\mathcal{A}$ we have:

$$
\Vert (e^{-u\tau + s\hat{\psi}} - 1) 1_a h \Vert_{\mathcal{B}_w} \leq \left( C_2 s\gamma \sup_a \psi_0^\gamma + C_3 u\gamma \sup_a \tau^\gamma \right) \Vert h \Vert_{\mathcal{B}_w}. \tag{7.1}
$$
In (7.1), multiplication by \( 1_a \) means that we restrict \( \tau, \tilde{\psi} \) to \( a \). The main result of this section reads as follows.

**Theorem 7.1.** Assume (H2) and suppose that \( \psi : \mathcal{M} \to \mathbb{R} \) satisfies (H5) with \( C' > C \int \tau^x d\mu_{\tilde{\phi}} \). Assume (H6) and (H7). Then

\[
\mathcal{P}(\phi + s\psi) = \frac{1}{\tau^x} \mathcal{P}(\phi + s\tilde{\psi})(1 + o(1)) \text{ as } s \to 0^+.
\]

7.1. Technical tools, family of eigenvalues of \( \hat{R}(u, s) \). Note that \( \hat{R}(u, 0) v = \hat{R}(u) v \) and recall from Sect. 5.1 that under (H1)–(H3), the family of eigenvalues \( \lambda(u) \) is well-defined on \([0, \delta_0]\) with \( \lambda(0) = 1 \). Recall that (H6) and (H7) hold for some \( \delta > 0 \). Throughout the rest of this work we let \( \delta_1 = \min\{\delta, \delta_0\} \).

**Lemma 7.2.** Assume (H1), (H2), (H5) and (H7). Then for all \( s \in (0, \delta_1) \), there exists \( c > 0 \) such that

\[
\|\hat{R}(u, s) - \hat{R}(u, 0)\|_{\mathcal{B} \to \mathcal{B}_w} \leq c s^\gamma.
\]

**Proof.** Using (4.1), write

\[
\hat{R}(u, s) - \hat{R}(u, 0) = r_0(u) \int_0^\infty R(\omega(t - \tau)(e^{s\tilde{\psi}} - 1)) e^{-ut} dt.
\]

By (H7), \( (e^{s\tilde{\psi}} - 1)1_a \in \mathcal{B} \) for any element \( a \) in the (Markov) partition \( \mathcal{A} \). Without loss of generality we assume that \( \text{supp} \omega(t - \tau) \) is a subset of a finite union \( \bigcup_{a \in \mathcal{A}_t} a \) of elements in \( \mathcal{A} \). Thus, \( \tau \) and \( t \) are of the same order of magnitude for \( a \in \mathcal{A}_t \) and

\[
\| (e^{s\tilde{\psi}} - 1)1_{\text{supp} \omega(t-\tau)} \|_{\mathcal{B}_w} \ll \max_{a \in \mathcal{A}_t} \| (e^{s\tilde{\psi}} - 1)1_a \|_{\mathcal{B}_w}.
\]

Note that

\[
\| R(\omega(t-\tau)(e^{s\tilde{\psi}} - 1)) v \|_{\mathcal{B}_w} \leq C \| R(\omega(t-\tau)) \|_{\mathcal{B} \to \mathcal{B}_w} \max_{a \in \mathcal{A}_t} \| (e^{s\tilde{\psi}} - 1)1_a \|_{\mathcal{B}_w}.
\]

By (H5) and (H7) (with \( u = 0 \)),

\[
\| (e^{s\tilde{\psi}} - 1)1_{\text{supp} \omega(t-\tau)} \|_{\mathcal{B}_w} \ll \| (e^{s\tilde{\psi}} - 1)1_a \|_{\mathcal{B}_w} \ll s^\gamma \sup_{a \in \mathcal{A}_t} \psi_0^\gamma \ll s^\gamma t^{\kappa \gamma}.
\]

Recall that \( \gamma < 1 \) if \( \kappa > 1 \). Putting the above together and recalling \( R(\omega(t - \tau)) = M(t) \), we obtain that for any \( \epsilon \in (0, 1 - \gamma) \),

\[
\|\hat{R}(u, s) - \hat{R}(u, 0)\|_{\mathcal{B} \to \mathcal{B}_w} \ll s^\gamma \int_0^\infty t^{\kappa \gamma} \| M(t) \|_{\mathcal{B} \to \mathcal{B}_w} dt \ll s^\gamma \int_0^\infty t^{\kappa - \epsilon} \| M(t) \|_{\mathcal{B} \to \mathcal{B}_w} dt.
\]

Proceeding as in the proof of Lemma 5.3, in particular using (5.1), we have

\[
\int_0^\infty t^{\kappa - \epsilon} \| M(t) \|_{\mathcal{B} \to \mathcal{B}_w} dt \ll \int_0^\infty t^{\kappa - \epsilon} (S(t+1) - S(t)) dt \text{ for } S(t) = \int_t^\infty \| M(x) \|_{\mathcal{B} \to \mathcal{B}_w} dx.
\]

This gives

\[
\int_0^\infty t^{\kappa - \epsilon} \| M(t) \|_{\mathcal{B} \to \mathcal{B}_w} dt \ll \int_0^\infty t^{\kappa - \epsilon} S(t) dt - \int_0^\infty t^{\kappa - \epsilon} S(t+1) dt = \int_0^\infty t^{\kappa - \epsilon} S(t) dt - \int_1^\infty t^{\kappa - \epsilon} \frac{1}{t} t^{\kappa - \epsilon} S(t) dt.
\]
Pressure Function and Limit Theorems

By assumption, \( \tau \in L^\kappa(\mu_\phi) \), so \( t^\kappa \mu_\phi(\tau > t) \leq \int_{\tau \geq t} t^\kappa d\mu_\phi \leq \int_Y t^\kappa d\mu_\phi < \infty. \) By (H2)(ii), \( S(t) \ll \mu_\phi(\tau > t). \) Thus,

\[
\int_0^\infty t^{k-\epsilon} \|M(t)\|_{\mathcal{B} \rightarrow \mathcal{B}_w} dt \ll \int_1^\infty t^{k-1-\epsilon} \mu_\phi(\tau > t) dt \leq \int_Y t^\kappa d\mu_\phi \int_1^\infty t^{-(1+\epsilon)} dt < \infty,
\]

which ends the proof. \( \square \)

Lemmas 5.3 and 7.2 ensure that \( (u, s) \rightarrow \hat{R}(u, s) \) is analytic in \( u \) and continuous in \( s \), for all \( s \in [0, \delta_0] \), when viewed as an operator from \( \mathcal{B} \) to \( \mathcal{B}_w \) with

\[
\|\hat{R}(u, s) - \hat{R}(0, 0)\|_{\mathcal{B} \rightarrow \mathcal{B}_w} \ll s^\gamma + q(u),
\]

where \( q(u) \) is as defined in Lemma 5.3.

Recall that \( \lambda(u) \) is well-defined for all \( u \in [0, \delta_1] \) with \( \delta_1 = \min\{\delta, \delta_0\} \). By (H6), there exists a family of eigenvalues \( \lambda(u, s) \) well-defined for \( u, s \in [0, \delta_1] \) with \( \lambda(0, 0) = 1 \). Throughout, let \( v(u, s) \) be a family of eigenfunctions associated with \( \lambda(u, s) \). The next result gives the continuity properties of \( v(u, s) \).

**Lemma 7.3.** Assume (H1), (H2), (H5) and (H6). Then there exists \( \delta_2 \leq \delta_1 \) such that for all \( u, s \in [0, \delta_2] \), there exists \( c > 0 \) such that

\[
\|v(u, s) - v(u, 0)\|_{\mathcal{B}_w} \leq cs^\gamma \log(1/s).
\]

**Proof.** This follows from Lemma 7.2 and (H6) (which holds for \( u \geq 0 \) and \( s \in [0, \delta_1] \)) together with the argument recalled in the proof of Lemma 5.4. \( \square \)

We recall \( \Pi(u) = \mu_\phi(1 - e^{-u\tau}) \) and set \( \Pi_0(s) := \mu_\phi(e^{s\bar{\psi}} - 1) \). The result below gives the asymptotic behaviour and continuity properties of \( \lambda(u, s) \).

**Lemma 7.4.** Assume (H1), (H2), (H5) (for some range of \( \kappa \)) and (H7). Then as \( u, s \rightarrow 0 \),

\[
1 - \lambda(u, s) = \Pi(u) + \Pi_0(s) + D(u, s),
\]

where \( |\frac{d}{du} D(u, s)| \ll (\log(1/u))^{k\gamma + 2}(s^\gamma + q(u)) + \mu_\phi(\tau > \log(1/u)) \) with \( q(u) \) as defined in Lemma 5.3.

**Proof.** Proceeding as in the proof of Lemma 5.5, write \( \lambda(u, s)v(u, s) = \hat{R}(u, s)v(u, s) \) for all \( u, s \in [0, \delta_1] \) with \( \lambda(0, 0) = 1 \) and \( v(0, 0) = \mu_\phi \). Normalising such that \( \langle v(u, s), 1 \rangle = 1 \),

\[
1 - \lambda(u, s) = \Pi(u) + \Pi_0(s) - W(u, s) - V(u, s)
\]

for

\[
W = \int_Y (e^{-u\tau} - 1)(e^{s\bar{\psi}} - 1) d\mu_\phi \quad \text{and} \quad V(u, s) = \langle (\hat{R}(u, s) - \hat{R}(0, 0))(v(u, s) - v(0, 0)), 1 \rangle.
\]

We first deal with \( V(u, s) \). Let \( Q(u, s) := \langle (\hat{R}(u, 0) - \hat{R}(0, 0))(v(u, s) - v(0, 0)), 1 \rangle \). Using (7.2),

\[
V(u, s) = r_0(u) \int_0^\infty e^{-ut} (e^{s\bar{\psi}} - 1)\omega(t - \tau)[v(u) - v(0)] dt + Q(u, s).
\]
By the argument used in the proof of Lemma 5.5,
\[ |Q(u, s)| \ll \|v(u, s) - v(0, 0)\|_{B_w} \Pi(u). \]

By (H2)(i),
\[ ((e^{\hat{\psi} \tau} - 1)\omega(t - \tau)[v(u) - v(0)], 1) \ll \| (e^{\hat{\psi} \tau} - 1)(v(u, s) - v(0, 0))_{B_w} \mu_{\hat{\phi}}(\omega(t - \tau)). \]
which together with (H7) (with \( u = 0 \)) gives
\[ \langle (e^{\hat{\psi} \tau} - 1)\omega(t - \tau)[v(u) - v(0)], 1 \rangle \ll s^\gamma \tau^\epsilon \| v(u, s) - v(0, 0)\|_{B_w} \mu_{\hat{\phi}}(\omega(t - \tau)). \]

Proceeding as in the proof of Lemma 5.5 and using that \( \int_Y \tau^\gamma d\mu_{\hat{\phi}} < \infty \),
\[ \left| \int_0^\infty e^{-ut} ((e^{\hat{\psi} \tau} - 1)\omega(t - \tau)[v(u, s) - v(0, 0)], 1) dt \right| \ll s^\gamma \| v(u, s) - v(0, 0)\|_{B_w} \int_Y \tau^\gamma e^{-ut} d\mu_{\hat{\phi}} \ll s^\gamma \| v(u, s) - v(0, 0)\|_{B_w}. \]

By a similar argument,
\[ \left| \int_0^\infty (e^{-ut} - 1) ((e^{\hat{\psi} \tau} - 1)\omega(t - \tau)[v(u, s) - v(0, 0)], 1) dt \right| \ll s^\gamma \| v(u, s) - v(0, 0)\|_{B_w}. \]

By Lemmas 5.4 and 7.3, \( \| v(u, s) - v(0, 0)\|_{B_w} \ll s^\gamma \log(1/s) + q(u)|\log q(u)| \). This together with the previous two displayed equations gives \( |V(u, s)| \ll s^\gamma (s^\gamma \log(1/s) + q(u)|\log q(u)|) \).

We continue with \( |d/du V(u, s)| \). Compute that
\[
\frac{d}{du} V(u, s) = \left\langle \frac{d}{du} \hat{R}(u, s)(v(u, s) - v(0, 0)), 1 \right\rangle + \left\langle (\hat{R}(u, s) - \hat{R}(0, 0)) \frac{d}{du} v(u, s), 1 \right\rangle.
\]

By (H5), (H7) and the argument used above in estimating \( V(u, s) \), we get
\[
\left| \left\langle \frac{d}{du} \hat{R}(u, s)(v(u, s) - v(0, 0)), 1 \right\rangle \right| \ll \left| \left\langle \frac{d}{du} \hat{R}(u, 0)(v(u, s) - v(0, 0)), 1 \right\rangle \right| \ll \| v(u, s) - v(0, 0)\|_{B_w} \int_0^\infty \tau \omega(t - \tau) e^{-ut} dt \ll \| v(u, s) - v(0, 0)\|_{B_w} \ll \log(1/u)(s + q(u)).
\]

By (H5), (H7) and Lemma 5.4, \( \| \frac{d}{du} v(u, s)\|_{B_w} \ll \| \frac{d}{du} v(u, 0)\|_{B_w} \ll \log(1/u) \). Thus,
\[
\left| \left\langle (\hat{R}(u, s) - \hat{R}(0, 0)) \frac{d}{du} v(u, s), 1 \right\rangle \right| \ll (s^\gamma + q(u)) \log(1/u)
\]
and \( |d/du V(u, s)| \ll (s^\gamma + q(u)) \log(1/u) \). We briefly estimate \( W(u, s) \). Compute that
\[
\left| \frac{d}{du} W(u, s) \right| \ll \int_{|\tau| < \log(1/u)} \tau e^{-\tau} |1 - e^{\hat{\psi} \tau}| d\mu_{\hat{\phi}} + \int_{|\tau| \geq \log(1/u)} \tau d\mu_{\hat{\phi}} \ll s^\gamma \int_{|\tau| < \log(1/u)} \tau^{\epsilon\gamma+1} d\mu_{\hat{\phi}} + \mu_{\hat{\phi}} (\tau \geq \log(1/u)) \ll s^\gamma (\log(1/u))^{\epsilon\gamma+2} + \mu_{\hat{\phi}} (\tau \geq \log(1/u)).
\]
The conclusion follows with \( D(u, s) = -(W(u, s) + V(u, s)) \).
For a further technical result exploiting (H7) we introduce the following notation. For \( u, s \geq 0 \), set \( g = s \tilde{\psi} - ut \), so \( \tilde{R}(u, s) = R(e^{s \tilde{\psi}}) \). For \( N > 1 \) and \( x \in [a] \), define the ‘lower’ and ‘upper’ flattened versions of \( g \) as

\[
g_N^-(x) = \begin{cases} g(x) & \text{if } \tau(y) \leq N \text{ for all } y \in a, \\ \inf_{y \in [a]} g(y) & \text{otherwise}, \end{cases}
\]

and

\[
g_N^+(x) = \begin{cases} g(x) & \text{if } \tau(y) \leq N \text{ for all } y \in a, \\ \sup_{y \in [a]} g(y) & \text{otherwise}. \end{cases}
\]

Since \( \psi \) is bounded above by (H5), monotonicity of the pressure function gives

\[
P(\tilde{\phi} + g_N^-) \leq P(\tilde{\phi} + g) \leq P(\tilde{\phi} + g_N^+) \leq P(\tilde{\phi}) + s \sup \tilde{\psi} < \infty \tag{7.4}
\]

for all \( u, s \geq 0 \). For fixed \( u, s \in [0, \delta_0] \), set \( \tilde{R}_N^\pm(u, s) = R(e^{s \tilde{\psi}}) \). By (H6), the associated eigenvalues \( \lambda_N^\pm(u, s) \) exist for all \( N \) and \( u, s \in [0, \delta_0] \).

**Lemma 7.5.** Assume (H2), (H5), (H6) and (H7). Then for fixed \( u, s \in [0, \delta_0] \),

\[
\lim_{N \to \infty} |\lambda(u, s) - \lambda_N^\pm(u, s)| \to 0.
\]

The reason to introduce \( g_N^\pm \) is that, unlike \( g \), the potentials \( g_N^\pm \) have summable variation, and therefore, \( P(\tilde{\phi} + g_N^+ - \tilde{\phi} - \tilde{\phi}^-) = \log \lambda_N^\pm(u, s) \) by [S99, Lemma 6]. Here [S99, Theorem 3] is used to equate Gurevich pressure in [S99, Lemma 6] and variational pressure in this paper, and then [S99, Theorem 4] together with the existence of the eigenfunctions \( v_N^\pm(u, s) \) and eigenmeasures \( m_N^\pm(u, s) \) of \( \tilde{R}_N^\pm(u, s) \) and its dual, to conclude that \( \tilde{\phi} + g_N^\pm \) are positively recurrent. From this, together with (7.4) and Lemma 7.5, we conclude

\[
P(\tilde{\phi} + s \tilde{\psi} - \tilde{u}) = \log \lambda(u, s). \tag{7.5}
\]

We note that this connection between the eigenvalues of a perturbed transfer operator and the pressure can be seen in similar contexts in [S06].

**Proof of Lemma 7.5.** Assume \( u \neq 0 \) and/or \( s \neq 0 \). Proceeding similarly to the argument of Lemma 7.2, we write

\[
\tilde{R}(u, s) - \tilde{R}_N^\pm(u, s) = \int_0^\infty R(\omega(t - \tau)(e^{s \tilde{\psi}} - e^{s \tilde{\psi}N})) \, dt. \tag{7.6}
\]

Without loss of generality we assume that \( \text{supp } \omega(t - \tau) \) is a subset of a finite union \( \bigcup_{b \in B_t} b \) of elements \( b \in \mathcal{A} \). Note that for any \( v \in C^\infty(Y) \),

\[
\| R(\omega(t - \tau)(e^{s \tilde{\psi}} - e^{s \tilde{\psi}N})) v \|_{B \to B_w} \leq C \| R(\omega(t - \tau)) \|_{B \to B_w} \max_{b \in B_t} \| (e^{s \tilde{\psi}} - e^{s \tilde{\psi}N}) 1_b v \|_{B_w}.
\]

We only have to consider those \( b \in B_t \) with \( b \cap \{ \tau > N \} \neq \emptyset \), otherwise \( (e^{s \tilde{\psi}} - e^{s \tilde{\psi}N}) 1_b = 0 \). This together with (H7) gives

\[
\max_{b \in B_t} \| (e^{s \tilde{\psi}} - e^{s \tilde{\psi}N}) 1_b v \|_{B_w} \ll \max_{b \in B_t} \sup_{b} \| g - \pm g_N \|_{L^\infty} \ll \tau^{\gamma_k} 1_{\{\tau > N\}}.
\]
Recall $\gamma < 1$ for $\kappa > 1$. By (H2) and the previous displayed equation, for any $\epsilon \in (0, 1 - \gamma)$,

$$\| \hat{R}(u, s) - \hat{R}_N^{\pm}(u, s)\|_{B \to B_w} \lesssim \int_N^\infty t^{\gamma \kappa} \| M(t) \|_{B \to B_w} dt = \int_N^\infty t^{-(1-\gamma-\epsilon)\kappa} t^{\kappa - \epsilon} \| M(t) \|_{B \to B_w} dt \leq N^{-(1-\gamma-\epsilon)\kappa} \int_N^\infty t^{\kappa - \epsilon} \| M(t) \|_{B \to B_w} dt. \tag{7.7}$$

By equation (7.3), $\int_0^\infty t^{\kappa - \epsilon} \| M(t) \|_{B \to B_w} dt < \infty$. Using (7.7) and (7.3),

$$\| \hat{R}(u, s) - \hat{R}_N^{\pm}(u, s)\|_{B \to B_w} \ll N^{-(1-\gamma-\epsilon)\kappa}.$$

This together with the argument recalled in the proof of Lemma 5.4 gives

$$\| v(u, s) - v_N^{\pm}(u, s)\|_{B \to B_w} \ll N^{-(1-\gamma-\epsilon)\kappa} \log N,$$

where for fixed $u, s \in [0, \delta_0)$, $v(u, s)$ and $v_N^{\pm}(u, s)$ are the eigenfunctions associated with $\lambda(u, s)$ and $\lambda_N^{\pm}(u, s)$, respectively. Thus,

$$\| \hat{R}(u, s) - \hat{R}_N^{\pm}(u, s)\|_{B \to B_w} \to 0, \quad \| v(u, s) - v_N^{\pm}(u, s)\|_{B_w} \to 0 \text{ as } N \to \infty.$$

The conclusion follows from these estimates together with the argument used in Lemma 5.5 and the first part of the proof of Lemma 7.4. \hfill \Box

7.2. Proof of Theorem 7.1.

Lemma 7.6. Assume that $\tilde{\psi} \leq C'$ (as in (H5)) and that $\mathcal{P}(\phi + s\psi) > 0$ for $s > 0$. Then $\mathcal{P}(\phi + s\psi - \mathcal{P}(\phi + s\psi)) = 0$.

Proof. Set $u_0 = \mathcal{P}(\phi + s\psi)$ which is positive for $s > 0$ by assumption. We first show that the pressures we are dealing with are finite. As in [S99, Lemma 2], finiteness of the transfer operator acting on constant functions is sufficient to give finiteness of the pressure, i.e., since we are dealing with positive $u_0$, we just need to show $\sup_{x \in Y} |(\hat{R}(u, s)1)(x)| < \infty$ for $u \geq 0$. We estimate

$$(\hat{R}(u, s)1)(x) = \sum_{F(x) = y} e^{(\phi + s\psi - u)(y)} \lesssim \sum_{F(y) = x} e^{\tilde{\psi}(y)} = (R_01)(x) < \infty,$$

because $\tilde{\psi} \leq C'$ by (H5).

To show that $\mathcal{P}(\phi + s\psi - u_0) \leq 0$, suppose by contradiction that $\mathcal{P}(\phi + s\psi - u_0) > 0$. We use the ideas of [S99, e.g. Theorem 2] to truncate the whole system, i.e., restrict to the system to the first $n$ elements of the partition $\mathcal{A}$ and the corresponding flow. We write the pressure of this system as $\mathcal{P}_n(\cdot)$, so [S99, Theorem 2] says that $\mathcal{P}_n(\phi + s\psi - u_0) > 0$ for all large $n$. By the definition of pressure, there exists a measure $\tilde{\mu}$ so that

$$h(\tilde{\mu}) + \int (\phi + s\psi - u_0) d\tilde{\mu} > 0.$$
Note that $\int \tau \, d\tilde{\mu} < \infty$ since $\tau$ is bounded on this subsystem. Abramov’s formula (3.3) implies that the projected measure $\mu$ [which relates to $\tilde{\mu}$ via (3.4)] has

$$h(\mu) + \int \phi + s\psi - u_0 \, d\mu > 0,$$

contradicting the choice $u_0 = P(\phi + s\psi)$.

To show that $P(\phi + s\psi - u_0) \geq 0$, we will use the continuity of the pressure function $u \mapsto P(\phi + s\psi - u)$ wherever this is finite (recall from above that we have finiteness for any $u \in [0, u_0)$). By the definition of pressure, for any $\epsilon \in (0, u_0)$, there exists $\mu'$ with

$$h(\mu') + \int \phi + s\psi - (u_0 - \epsilon) \, d\mu' > 0,$$

By (3.4), any invariant probability measure for the flow corresponds to an invariant probability measure $\bar{\mu}'$ for the map $F$. By Abramov’s formula,

$$h(\bar{\mu}') + \int \phi + s\psi - (u_0 - \epsilon) \, d\bar{\mu}' = \left( h(\mu') + \int \phi + s\psi - (u_0 - \epsilon) \, d\mu' \right) \int \tau \, d\bar{\mu}' > 0$$

regardless of whether $\int \tau \, d\bar{\mu}'$ is finite or not. By continuity in $u$, $P(\phi + s\psi - u_0) \geq 0$ as required. 

The following result is a consequence of (7.5) and of Lemma 7.4.

**Lemma 7.7.** Assume the setting of Lemma 7.4. Suppose that there exists $a > 0$ such that $s = O(u^a)$, as $u \to 0$. Then as $u \to 0^+$,

$$\frac{d}{du} P(\phi + s\psi - u) = -\tau^*(1 + o(1)).$$

**Proof.** By (7.5) and Lemma 7.4,

$$\frac{d}{du} P(\phi + s\psi - u) = \frac{d}{du} \log \lambda(u, s) = \frac{d}{du} (\Pi(u) + D(u, s)),$$

where $\frac{d}{du} D(u, s) = O\left((\log(1/u))^{\nu_0 + 2}(s' + q(u)) + \mu(\tau > \log(1/u))\right)$. Also, compute that

$$\frac{d}{du} \Pi(u) = \int_Y \tau e^{-u\tau} \, d\mu_\phi = \int_Y \tau \, d\mu_\phi + \int_Y \tau (e^{-u\tau} - 1) \, d\mu_\phi.$$

Since $\tau |e^{-u\tau} - 1|$ is bounded by the integrable function $\tau$ and it converges pointwise to 0, it follows from the Dominated Convergence Theorem that $\int_Y \tau (e^{-u\tau} - 1) \, d\mu_\phi \to 0$, as $u \to 0^+$. Hence, $\frac{d}{du} \Pi(u) = \tau^*(1 + o(1))$.

Since $\tau \in L^1(\mu_\phi)$ by assumption, $\mu_\phi(\tau > \log(1/u)) \to 0$, as $u \to 0$. To conclude, note that since for some $a > 0$, $s = O(u^a)$, as $u \to 0$, we have $D(u, s) = o(1)$. 

We can now complete
Proof of Theorem 7.1. Set \( r(u, s) = \frac{d}{da} \mathcal{P}(\phi + s\psi - u) \). By Lemma 7.7, as \( u \to 0 \) and \( s = O(u^a) \) for some \( a > 0 \),

\[
r(u, s) = -\tau^s(1 + o(1)).
\]

For any small \( u_0 > 0 \), integration gives

\[
\mathcal{P}(\phi + s\psi - u_0) - \mathcal{P}(\phi + s\psi) = \int_0^{u_0} r(u, s) \, du = -\tau^s u_0(1 + o(1)). \tag{7.8}
\]

The convexity of \( s \mapsto \mathcal{P}(\phi + s\psi) \) implies that \( \frac{d}{ds} \mathcal{P}(\phi + s\psi) = \int \psi \, d\mu_\phi = \frac{1}{\tau} \int \psi \, d\mu_\phi \). Thus \( \mathcal{P}(\phi + s\psi) \geq \frac{C}{\tau} \int \psi \, d\mu_\phi \) since \( \int \psi \, d\mu_\phi > 0 \); this is guaranteed by our assumption that \( C' > C \int \tau^s \, d\mu_\phi \). Hence, \( u_0 = u_0(s) = \mathcal{P}(\phi + s\psi) \gg s \) and such \( u_0 \) satisfies the assumptions of Lemma 7.7 with \( a = 1 \). Thus, (7.8) holds for this \( u_0 \).

By Lemma 7.6 applied to \( u_0 = u_0(s) = \mathcal{P}(\phi + s\psi) \), we obtain \( \mathcal{P}(\phi + s\psi - u_0) = 0 \). Thus, the left hand side of (7.8) is \( -\mathcal{P}(\phi + s\psi) \). By assumption, \( u_0(s) > 0 \), for \( s > 0 \). The continuity property of the pressure function gives \( u_0(s) \to 0 \) as \( s \to 0 \). Hence, (7.8) applies to \( u_0(s) = \mathcal{P}(\phi + s\psi) \). Thus, \( \mathcal{P}(\phi + s\psi) = \frac{1}{\tau} \mathcal{P}(\phi + s\psi)(1 + o(1)) \), which ends the proof. \( \square \)

8. Pressure Function and Limit Theorems

For \( \psi : \mathcal{M} \to \mathbb{R} \), define \( \bar{\psi} : Y \to \mathbb{R} \) as in (3.2) and let \( \psi_T = \int_0^T \psi \circ f_i \, dt \). Throughout this section we assume that \( \bar{\psi} \) satisfies (H5); in particular, we require that \( \bar{\psi} = C' - \psi_0 \), with \( \psi_0 \sim C\tau^\rho(1 + o(1)) \), \( \int \tau^\rho \, d\mu_\phi < \infty \) for some \( C, C' > 0 \). For \( s \) real, \( s \geq 0 \), define

\[
\hat{R}_\psi(s)v := R(e^{s\bar{\psi}}) = e^{sC'} R(e^{-s\psi_0})v =: e^{sC'} \hat{R}_1(s).
\]

As in Sect. 4.3 (when making assumptions on \( \hat{R}(u) \)), we write

\[
\hat{R}_1(s) = r_0(s) \int_0^\infty R(\omega(t - \psi_0)) e^{-st} \, dt = r_0(s) \int_0^\infty M_0(t) e^{-st} \, dt, \tag{8.1}
\]

where \( M_0(t) := R(\omega(t - \psi_0)) \) and \( \omega : \mathbb{R} \to [0, 1] \) is an integrable function with \( \text{supp } \omega \subset [-1, 1] \) and \( r_0(0) = 1 \). Similarly to (H2), we require that

(H8) There exists a function \( \omega \) satisfying (8.1) and \( C_\omega > 0 \) such that

(i) for any \( t \in \mathbb{R}_+ \) and for all \( h \in \mathcal{B} \), we have \( \omega(t - \psi_0)h \in \mathcal{B}_\omega \) and for all \( v \in C^a(Y) \),

\[
\langle \omega(t - \psi_0)v h, 1 \rangle \leq C_\omega \|v\|_{C^a(Y)} \|h\|_{\mathcal{B}_\omega} \mu_\phi(\omega(t - \psi_0)).
\]

(ii) there exists \( C > 0 \) such that for all \( T > 0 \),

\[
\int_T^\infty \|M_0(t)\|_{\mathcal{B} \to \mathcal{B}_\omega} \, dt \leq C \mu_\phi(\psi_0 > T).
\]

Remark 8.1. In practice, checking (H8) requires no extra difficulty compared to checking (H2). But in the generality of the present abstract framework, there is no obvious way of deriving (H8) from (H2).

Summarising the arguments used in the proof of Proposition 5.1 and Theorem 7.1 together with Proposition 6.1, in this section we obtain
Theorem 8.2. Assume (H1) and (H8) and \( C' > C \int \tau \, d\mu \) as in Theorem 7.1. Let \( \psi : \mathcal{M} \to \mathbb{R} \) and assume that \( \tilde{\psi} \) satisfies (H5), (H6) and (H7) (with \( u = 0 \)). Set \( \psi^* = \int_Y \psi \, d\mu_{\tilde{\phi}} \). The following hold as \( T \to \infty \).

(a) Suppose that (H4)(i) holds and that \( \mu(\psi_0 > t) \sim \mu(\tau^k > t) \) with \( k \) in (some subset of) \((0, \beta)\).

(i) When \( \beta < 2 \) and \( k \in (\beta/2, \beta) \), set \( b(T) \) such that \( T \ell(b(T))/b(T)^{\frac{\beta}{k}} \to 1 \). Then
\[
\frac{1}{b(T)}(\psi_T - \psi^* \cdot T) \to^d G_{\beta/k}, \quad \text{where} \quad G_{\beta/k} \text{ is a stable law of index } \beta/k.
\]
This is further equivalent to \( P(\tilde{\phi} + s \psi) = \psi^* s + s^{\beta/k}_\ell(1/s)(1 + o(1)) \), as \( s \to 0 \).

(ii) If \( \beta \leq 2 \) and \( k = \beta/2 \), set \( b(T) \) such that \( T \ell(b(T))/b(T)^{\frac{\beta}{k}} \to c > 0 \). Then
\[
\frac{1}{b(T)}(\psi_T - \psi^* \cdot T) \to^d N(0, c) \text{ and this is further equivalent to } P(\tilde{\phi} + s \psi) = \psi^* s + s^2 \ell(L(1/s)(1 + o(1))) \text{ as } s \to 0.
\]

(b) Suppose that (H4)(ii) holds and further assume that \( \mu(\psi_0 > t) \ll \mu(\tau^k > t) \) with \( k \in (0, \beta/2) \), and \( R \tilde{\psi} \in B \). Then there exists \( \sigma \neq 0 \) such that
\[
\int_Y \psi_0 \, d\mu_{\tilde{\phi}} > 0 \quad \text{and } \psi_0 \to^d N(0, \sigma^2) \text{ and this is further equivalent to } P(\tilde{\phi} + s \psi) = \psi^* s + \sigma^2 s^2(1 + o(1)) \text{ as } s \to 0.
\]
Moreover, if (H6) and (H7) hold for all \( u, s \in [0, \delta] \), then in both cases (a) and (b) we have \( P(\tilde{\phi} + s \psi) = \frac{1}{\tau} P(\tilde{\phi} + s \psi)(1 + o(1)) \), for \( \tau^* = \int_Y \tau \, d\mu_{\tilde{\phi}} \).

Proof. We start by noting that the proofs of the results used in the proofs of Theorems 7.1 and Propositions 5.1 and 6.1 essentially go through when replacing \( \tau \) by \( \tau^k \). We briefly summarize the required arguments.

For \( s > 0 \), let \( \lambda(s) \), \( \lambda_1(s) \) be the families of eigenvalues associated with \( \hat{R}_\psi(s) \) and \( \hat{R}_1(s) \), respectively. Note that \( \lambda(s) = e^{sC'} \lambda_1(s) \). Hence,
\[
\lambda(s) - 1 = sC' + \lambda_1(s) - 1 + s^2 C' + O(s^3). \tag{8.2}
\]
Further, by (7.5), \( P(\tilde{\phi} + s \psi) = \log \lambda(s) \). Similar to the proofs of Proposition 5.1 and Proposition 6.1, to conclude that (a) and/or (b) hold, we just need to estimate \( 1 - \lambda(s) \).

For the proof of (a) and (b), we note that under (H5)–(H8) (where (H8) and (H7) with \( u = 0 \) are the analogues of (H2) and (H3) with \( \tau \) replaced by \( \psi_0 \)), Lemma 5.5 gives \( 1 - \lambda_1(s) = \Pi_1(s)(1 + O(q_1(s)| \log(q_1(s))|)) \), where \( q_1(s) = s + \mu(\psi_0 > 1/s) = s + s^{\beta/k} \ll s^{\beta/k} \) and \( \Pi_1(s) = \mu_\phi(e^{s\psi_0} - 1) \). Hence,
\[
1 - \lambda_1(s) = \Pi_1(s)(1 + O(s^{\beta/k} \log(1/s))).
\]

In case (a) (i), the argument recalled in the proof of Corollary 5.6 (ii) gives \( \Pi_1(s) = s \int_Y \psi_0 \, d\mu_{\tilde{\phi}} + s^{\beta/k}_\ell(1/s)(1 + o(1)) \). This together with (8.2) gives
\[
\lambda(s) - 1 = \left( C' - \int_Y \psi_0 \, d\mu_{\tilde{\phi}} \right) s + s^{\beta/k}_\ell(1/s)(1 + o(1)) = \psi^* s + s^{\beta/k}_\ell(1/s)(1 + o(1)).
\]

As a consequence, \( P(\tilde{\phi} + s \psi) = \psi^* s + s^{\beta/k}_\ell(1/s)(1 + o(1)) \). Similarly, by the argument used in the proof of Proposition 5.1 (i), this expansion of the eigenvalue/pressure is equivalent to \( \frac{1}{b(T)}(\tilde{\psi}_n - \psi^* \cdot n) \to^d G_{\beta/k}, \) where \( \tilde{\psi}_n = \sum_{j=0}^{n-1} \tilde{\psi} \circ F^j \). Further, by the argument used in Proposition 6.1 (i) with \( \beta < 2 \) this is further equivalent to \( \frac{1}{b(T)}(\psi_T - \psi^* \cdot T) \to^d G_{\beta/k}, \) which completes the proof of (a) (i).
The proof of (a(ii)) goes similar with the versions of the proofs of Proposition 5.1 (i), Proposition 6.1 (i) with \( \beta < 2 \) replaced by the argument used in the proofs of Proposition 5.1 (i), Proposition 6.1 (i) with \( \beta = 2 \).

The proof of (b) goes again similarly with the proofs of Proposition 5.1 (i), Proposition 6.1 (i) replaced by the argument used in the proofs of Proposition 5.1 (ii), Proposition 6.1 (ii).

Finally, if (H6) for all \( u, s \in [0, \delta_0) \) and (H7) also hold, then Theorem 7.1 applies and ensures that \( \mathcal{P}(\phi + s\psi) = \frac{1}{\tau^s}\mathcal{P}(\bar{\phi} + s\bar{\psi})(1 + o(1)) \), ending the proof. \( \square \)

A. Checking (H1)–(H8) for the Almost Anosov Flow

We start with a technical result that will be essential in verifying (H2) and (H6).

**Lemma A.1.** Assume that \( w(x, y) \) is a homogeneous function of degree \( \rho \) as in Proposition 2.2. Then

\[
\sup_k \left\{ \sup_{\tau = k} \tau - \inf_{\tau = k} \tau \right\} < \infty.
\]

**Proof.** Recall that \( \hat{\tau}(x, y) = \min\{t > 0 : \Phi^\text{hor}_t(x, y) \in \hat{W}^s\} \) and that \( |\tau - \hat{\tau}| = O(1) \). From Lemma 2.3 we know that \( r = \hat{\tau} + \Theta(\hat{\tau}) + O(1) \). We will first show that if \( \hat{\tau} \) varies between, say, \( n \) and \( n + 1 \), then the corresponding \( r \) varies by an amount of \( O(1) \) as well.

Indeed, take \( (x, y) \) and \( (x', y') \) arbitrary such that \( n \leq \hat{\tau}(x, y), \hat{\tau}(x', y') \leq n + 1 \). Define \( T = \hat{\tau}(x, y) \) and abbreviate \( q(t) = (x(t), y(t)) = \Phi^\text{hor}_{t_0}(x, y) \) for \( 0 \leq t \leq T \). There is \( t_0 \in \mathbb{R} \) with \( |t_0| \leq 1 \) such that the \( y \)-component \( \Phi^\text{hor}_{t_0}(\hat{\tau}, \hat{y}) \) is \( y \). Also write \( q'(t) = (x'(t), y'(t)) = \Phi^\text{hor}_{t-\tilde{t}}(x', y') \), and the Euclidean distance \( \epsilon(t) = |q'(t) - q(t)| \).

Clearly \( |w(q'(t)) - w(q(t))| \ll |\nabla w(q(t))|\epsilon(t) \), so \( \epsilon(0) \ll T^{-(1+\beta)} \) by (2.3). However, since \( \hat{q}'(0) - q(0) \) is roughly in the unstable direction, \( \epsilon(t) \) will increase to size \( O(1) \) as \( t \) increases to \( \hat{\tau}(q') \). This is too large, but we can set \( T_1 := \min\{t > 0 : x(t) = y(t)\} \), and then estimate \( \epsilon(T_1) \) as follows. Take \( T_1' := \min\{t > 0 : x'(t) = y'(t)\} \), then \( |T_1' - T_1| = O(1) \) and we can write \( q(T_1) = (\delta, \delta), q'(T_1') = (\delta', \delta') \) with \( \epsilon' := \delta' - \delta \). Furthermore, since \( L \) from (2.8) is constant on integral curves, we have

\[
L(x, y) = x^u y^v \left( \frac{a_0}{v} x^2 + \frac{b_2}{u} y^2 \right) = \delta^{u+v+2} \left( \frac{a_0}{v} + \frac{b_2}{u} \right),
\]

(A.1)
and

\[ L(q'(0)) = L(x + \epsilon, y) = (x + \epsilon)^u y^v \left( \frac{a_0}{v} (x + \epsilon)^2 + \frac{b_2}{v} y^2 \right) = (\delta + \epsilon')^{u+v+2} \left( \frac{a_0}{v} + \frac{b_2}{u} \right). \]

Taking the difference of both expressions, we obtain

\[ \frac{\epsilon}{x} u L(x, y) \left( 1 + \frac{2a_0}{ua_0x^2 + vb_2y^2} + O \left( \frac{\epsilon}{x} \right) \right) = \frac{\epsilon'}{\delta} (u + v + 2) L(x, y) \left( 1 + O \left( \frac{\epsilon'}{\delta} \right) \right). \]

Divide by \((u + v + 2)L(x, y)/\delta\) and ignore the quadratic error terms. Then we have

\[ \epsilon' \sim \frac{\epsilon}{u + v + 2} \left( 1 + \frac{2a_0}{vb_2y^2} \right) \delta \epsilon x. \]

But \(\delta\) can be estimated in terms of \(x\) using (A.1), and since \(\frac{u}{u+v+2} = \frac{1}{2\beta}\) and \(\frac{a_0u}{b_2v} = \frac{c_0}{c_2}\), we obtain

\[ \epsilon' \sim \frac{\epsilon}{2\beta} x \frac{1}{\beta - 1} y \frac{1}{\beta - 2} \left( \left( 1 + \frac{c_0}{c_2} \right) \left( 1 + \frac{c_0}{c_2} \right) \right)^{-\frac{1}{\beta-2}} \text{ as } n \to \infty. \]

Rewriting \(x\) and \(\epsilon\) in terms of \(T\) using (2.3), we obtain \(\epsilon' \ll T^{-\frac{\rho}{2}}\). Next, because the vector-valued function \(\nabla w\) is homogeneous with exponent \(\rho - 1\), Proposition 2.2 gives for \(\rho < 2\):

\[ \int_0^{T_1} |w(q'(t)) - w(q(t))| \, dt \ll \sup_{t \in [0, T_1]} |w(q(t))| \, dt + O(1) \]
\[ \ll \epsilon' T^{1-\frac{\rho-1}{2}} + O(1) = T^{-\frac{\rho}{2}} + O(1). \]

The integral \(\int_{T_1}^T \|w(q'(t)) - w(q(t))\| \, dt\) is dealt with in the same way, but now integrating backwards from \(\Phi_{\text{hor}}^\tau(x, y)\) and \(\Phi_{\text{hor}}^{\tau'}(x', y')\). Therefore \(\int_0^\tau w(q'(t)) - w(q(t)) \, dt\) varies at most \(O(1)\) on the region \(\{(x, y) : n \leq \hat{r} \leq n + 1\}\).

Since also \(\int_0^\tau w(q(t)) \, dt = o(T)\), we can find \(N \in \mathbb{N}\) independent of \(n\) such that \(\tau = \int_0^\tau 1 + w(q(t)) \, dt + O(1)\) varies by at least 1 (but at most by \(O(N)\)) over \([n \leq \hat{r} \leq n + N]\), and therefore \(r\) varies by at least 1 on this region. It follows that for each \(k\), \(\{r = k\} \subset \{n \leq \hat{r} \leq n + N\}\) for some \(n = n(k)\) and \(\sup_{r=k} \tau - \inf_{r=k} \tau\) is bounded, uniformly in \(k\).

The proof for \(\rho \geq 2\) goes likewise. \(\square\)

A.1. Verifying (H1): recalling previously used Banach spaces. Charts and distances: Throughout, \(\mathcal{W}^s\) denotes the set of admissible leaves, which consists of maximal stable leaves in elements of the partition \(\mathcal{Y} = \{Y_j\}_j = \{P_i\} \cup \{(r = k)\}_{k \geq 2}\). It is convenient to arrange the enumeration of \(\mathcal{Y}\) such that \(Y_j = \{r = j\}\) for \(j \geq 2\), and use indices \(j \leq 1\) for the remaining (parts of) \(P_i\). To define distances between leaves, as in [BT17, Section 3.1], we use charts \(\chi_j : [0, L_u(Y_j)] \times [0, 1] \to Y_j\), where \(L_u(Y_j)\) is the length of the (largest) unstable leaf in \(Y_j\). For any leaf \(W \subset Y_j\), we have the parametrisation

\[ \chi_j^{-1}(W) = \{(g_{Y_j}, w(\rho), \rho \in [0, 1]\}. \]  
(A.2)
so \( g_{Y_j} \) is a parametrisation of \( W \) in the chart. Suppressing \( Y_j \) and using \( g \) and \( \tilde{g} \) for close-by stable leaves \( W \subset Y_k \) and \( \tilde{W} \in \mathcal{W}^s \subset Y_k \) we define their by

\[
d(W, \tilde{W}) = \begin{cases} 
\sup_{x \in [0,1]} |g(x) - \tilde{g}(x)| & \text{if } k = \ell; \\
\sup_{x \in [0,1]} |g(x) - L_u(Y_k) - \tilde{g}(x)| + \sum_{j=k+1}^{l-1} L_u(Y_j) & \text{if } 2 \leq k < \ell; \\
\infty & \text{otherwise},
\end{cases}
\]

where \( g \) and \( \tilde{g} \) are parametrisations of \( W \) and \( \tilde{W} \) in the appropriate chart. Here an empty sum \( \sum_{j=k+1}^{l-1} \) is 0 by convention.

From here on, in the notation \( \int_W \cdot d\mu^s \), the measure \( \mu^s \) refers to the SRB measure \( \mu_{\tilde{g}} \) conditioned on the stable leaf \( W \); similarly for \( m^s \) and Lebesgue measure. Hence the norms defined below are w.r.t. the invariant measure, not the conformal measure as in [BT17]. It is possible to do this due to Lemma A.2, specifically (A.7).

**Definition of the norms**

Given \( h \in C^1(Y, \mathbb{C}) \), define the weak norm by

\[
\|h\|_{B_w} := \sup_{W \in \mathcal{W}^s} \sup_{|\varphi|_{C^1(W)} \leq 1} \int_W h\varphi \ d\mu^s. \tag{A.3}
\]

Given \( q \in [0,1) \) we define the strong stable norm by

\[
\|h\|_s := \sup_{W \in \mathcal{W}^s} \sup_{|\varphi|_{C^1(W)} \leq 1} \int_W h\varphi \ d\mu^s. \tag{A.4}
\]

Finally, we define the strong unstable norm by

\[
\|h\|_u := \sup_{W, \tilde{W} \in \mathcal{W}^s \cap Y_k} \sup_{|\varphi|_{C^1(W),|\tilde{\varphi}|_{C^1(\tilde{W})}} \leq 1} \frac{1}{d(W, \tilde{W})} \left| \int_W h\varphi \ d\mu^s - \int_{\tilde{W}} h\tilde{\varphi} \ d\mu^s \right|, \tag{A.5}
\]

where \( d(\varphi, \tilde{\varphi}) = |\varphi \circ \chi_\ell(g(\eta), \eta) - \tilde{\varphi} \circ \chi_\ell(\tilde{g}(\eta), \eta)|_{C^1([0,1])} \).

The strong norm is defined by \( \|h\|_B = \|h\|_s + \|h\|_u \).

**Definition of the Banach spaces**

We define \( B \) to be the completion of \( C^1 \) in the strong norm and \( B_w \) to be the completion in the weak norm. As clarified in [BT17, Lemma 3.2, Lemma 3.3, Proposition 3.2], (H1) holds with \( \alpha = \alpha_1 = 1 \).

The spaces \( B \) and \( B_w \) defined above are simplified versions of functional spaces defined in [DL08], adapted to the setting of \( (F, Y) \). The main difference in the present setting is the simpler definition of admissible leaves and the absence of a control on short leaves. This is possible due to the Markov structure of the diffeomorphism.

As this is the same Banach space as in [BT17], most parts of (H1) can be taken from there. For \( H1(v) \), which is concerned with the transfer operator w.r.t. \( \mu_{\tilde{g}} \), we first need a lemma.

**Lemma A.2.** Let \( \gamma = \gamma(q) \) be the angle between the stable and unstable leaf at \( q \) and \( h^u_0 = \frac{d\mu^u}{dm^u} \) be the density of \( \mu_{\tilde{g}} \) conditioned on unstable leaves. Then

\[
\int_{W_s} R v \cdot \varphi \ d\mu^s = \sum_j \int_{W_j} v \cdot \varphi \circ F \cdot K^u_{W_j} d\mu^s, \tag{A.6}
\]
where the sum is over all preimage leaves \( W_j = F^{-1}(W^s) \cap \{ r = j \} \) and

\[
K^u_{W_j} = \frac{J^s_{\mu \phi} F}{J_{\mu \phi} F} = \frac{1}{J^u_{m \phi} F h_0 \sin \gamma} \frac{(h_0 \sin \gamma) \circ F}{h_0 \sin \gamma}
\]  

(A.7)

is piecewise \( C^1 \) on unstable leaves.

**Proof.** We have the pointwise formulas for \( R_0 : L^1(m_\phi) \to L^1(m_\phi) \) and \( R : L^1(\mu_\phi) \to L^1(\mu_\phi) \):

\[
R_0 v = 1_Y \frac{v}{|DF|} \circ F^{-1}, \quad Rv = 1_Y \frac{h_0 \circ F^{-1} v}{h_0} \circ F^{-1},
\]

where \(|DF| = J_{m \phi} = |\text{det}(DF)|\). This also shows that \( J_{\mu \phi} F = J_{m \phi} \frac{h_0}{h_0 \circ F^{-1}} \) and analogous formulas hold for \( J_{m} F \) and \( J_{u} F \). Integration over a stable leaf \( W \in \Lambda^s \) with preimage leaves \( W_j \) gives

\[
\int_W R_{\mu \phi} v \varphi d\mu^s = \int_W \frac{h_0 \circ F^{-1}}{h_0} \frac{v}{|DF|} \circ F^{-1} \varphi h_0^s dm^s
\]

\[
= \sum_j \int_{W_j} \frac{J^s_{m \phi} F}{J^s_{\mu \phi} F} \frac{h_0}{h_0 \circ F} v \varphi \circ F \frac{h_0^s}{h_0^s} dm^s
\]

\[
= \sum_j \int_{W_j} \frac{J^u_{m \phi} F}{J^u_{\mu \phi} F} v \varphi \circ F d\mu^s = \sum_j \int_{W_j} v \varphi \circ F K^u_{W_j} d\mu^s.
\]

Since \( d\mu^u = h_0^u dm^u \) for a \( C^1 \) density \( h_0^u \), and \( dm_\phi = dm^s dm^u \sin \gamma \), whence \( J_{m \phi} F = J_{m} F \cdot J_{mu} F \cdot \frac{\sin \gamma \circ F}{\sin \gamma} \), the other formula \( K^u_W = \frac{1}{J^u_{m \phi} F} \frac{(h_0^u \sin \gamma) \circ F}{h_0^u \sin \gamma} \) follows as well. Then

[BT17, Equation (18)], leading to the parametrisation of the unstable foliation of the induced map over \( \hat{f} = \Phi^h_1 \), shows that this foliation is \( C^1 \). The analogous statement holds for the stable foliation. To obtain the unstable/stable foliations of \( F \), we need to blow a bounded and piecewise \( C^1 \) amount of time (see Lemma A.1). Therefore \( q \mapsto \gamma(q) \) is piecewise \( C^1 \). Hence the latter expression of \( K^u_W \) shows that it is piecewise \( C^1 \) on unstable leaves. \( \Box \)

Now \((H1)\(v\)) follows as in [BT17, Lemma 3.3], with \( J_{\mu \phi} \) and \( K^u_{W_j} \) instead of \(|DF|^{-1} \) and \(|DF|^{-1} J_{W_j} F \); this can be done because \( K^u_W \) is piecewise \( C^1 \) on unstable leaves by Lemma A.2.

### A.2. Verifying \((H2)\) and \((H8)\)

Let \( \omega : \mathbb{R} \to [0, 1] \) be a function with \( \text{supp} \omega \subset [-1, 1] \) and \( \int \omega(x) \, dx = 1 \). To fix a choice that suffices for the present purpose we take \( \omega = 1_{[0,1]} \); then \( \gamma_1 = \frac{1}{3} \) and \( \gamma_2 = \frac{1}{6} \) (see Remark 4.1) and in particular, \( \omega(t-\tau) = 1_{[t \leq \tau \leq t+1]} \). The first result below verifies assumption \((H2)\(i\)).

**Proposition A.3.** There is \( C_\omega \) such that

\[
\int_Y \omega(t-\tau) v d\mu_\phi \leq C_\omega \|v\|_{B_w} \int_Y \omega(t-\tau) d\mu_\phi
\]

for all \( t \geq 0 \) and \( v \in B_w \).
Proof. By Lemma A.1, there is $N$ (independent of $t$) and $k(t)$ such that

$$E := \{ q \in f^{-1}(P_0) \setminus P_0 : k(t) \leq r(q) \leq k(t) + N \}$$

contains $\text{supp}(\omega(t - \tau))$. We split $v = v^+ - v^-$ into its positive and negative parts and treat them separately. Also we assume without loss of generality that $0 \leq \omega \leq 1$ (otherwise we split $\omega(t - \tau)$ into its positive and negative parts as well). Then $\int \omega(t - \tau) v^+ d\mu_\tilde{\phi} \leq \int_E v^+ d\mu_\tilde{\phi}$.

Let $W^s$ denote the stable foliation of $F$ and decompose the measure $\mu_\tilde{\phi}$ as $\int v^+ d\mu_\tilde{\phi} = \int_{W^s} v^+ d\mu_w d\nu$. Note that $E$ is the union of leaves in $\tilde{W}^s$, so $I_E$ is constant on each $W^s \in \tilde{W}^s$. Take $\varphi : E \to \mathbb{R}^+$ arbitrary such that $\varphi |_{W^s} \in C^1(W^s)$ with $\| \varphi \|_{C^1(W^s)} \leq 1$ for each $W^s \in \tilde{W}^s \cap E$. Similar to [BT17, Proposition 3.1], we get

$$\int_E v^+ \varphi d\mu_\tilde{\phi} = \int_{\tilde{W}^s \cap E} \int_{W^s} v^+ \varphi d\mu_w d\nu \leq \int_{\tilde{W}^s \cap E} \| v^+ \|_{B_w} \| \varphi \|_{C^1(W^s)} d\nu$$

$$\leq \| v^+ \|_{B_w} \mu_\tilde{\phi}(E) \ll \| v^+ \|_{B_w} \int_{k(t)}^{k(t)+N} \int_Y \omega(s - \tau) d\mu_\tilde{\phi} ds$$

$$\ll \| v^+ \|_{B_w} N \int_Y \omega(t - \tau) d\mu_\tilde{\phi}.$$  

The same holds for $v^-$, and this ends the proof. \qed

The next result verifies assumption (H2)(ii).

**Proposition A.4.** Let $M(t) = R(\omega(t - \tau))$. Then $\int_T^\infty \| M(t) \|_{B \to B_w} dt \ll T^{-\beta}$.

*Proof.* We need to estimate the $B_w$-norm of $M(t) = R(\omega(t - \tau) v)$. This means that we need to take some leaf $W^s \in \tilde{W}^s$, the collection of stable leaves in $Y$ stretching across an element of the Markov partition of $F$, and compute (as in Lemma A.2) that

$$\int_{W^s} M(t) v \cdot \varphi d\mu^s = \sum_j \int_{W^s_j} \omega(t - \tau) v \cdot \varphi \circ F \cdot K_{W^s_j}^u d\mu^s.$$  

As in the proof of Proposition A.3, we can split $v = v^+ - v^-$ and use that $\{ t - 1 \leq \tau \leq t + 1 \} \subset E := \{ k(t) \leq r \leq k(t) + N \}$. Thus, following [BT17, Proposition 3.2 (weak norm)] and [BT17, Equation (42)], the integral for $v^+$ is bounded by

$$\sum_{j=k(t)}^{k(t)+N} \int_{W^s_j} v^+ J_{W^s_j} F |DF|^{-1} \cdot \varphi \circ F d\mu^s \leq \| v^+ \|_{B_w} \| \varphi \|_{C^1(W^s)} \sum_{j=k(t)}^{k(t)+N} \int_{W^s_j} K_{W^s_j}^u d\mu^s$$

$$\ll \| v^+ \|_{B_w} \sum_{j=k(t)}^{k(t)+N} \mu_\tilde{\phi}(\{ r = j \})$$

$$\ll \| v^+ \|_{B_w} N \mu_\tilde{\phi}(\{ r = k(t) \}).$$

For $v^+$ and $v^-$ together, this gives $\int_T^\infty \| M(t) \|_{B \to B_w} dt \ll \int_T^\infty \mu_\tilde{\phi}(\{ r = k(t) \}) dt \ll \mu_\tilde{\phi}(\{ \tau \geq T \})$ and the proposition follows. \qed

Assumption (H8) is the same as (H2), with $\tau$ replaced by $\psi_0$ and $e^{-u\tau}$ by $e^{-s\psi_0}$. Its verification is entirely analogous to the above.
A.3. Verifying that \( R\xi \in \mathcal{B} \) for a large class of \( \xi \) (including \( \tilde{\psi} \) in Theorem 2.5 (b)) and completing the verification of (H4). Assumption (H4)(i) and the tail estimate part of (H4)(ii) (so that \( \tau \in L^2(\mu_\phi) \)) is verified in Proposition 2.4. To check the remaining part of (H4) and assumption on \( \tilde{\psi} \) in Theorem 2.5 (b) we give a more general result in Lemma A.5 below. This result ensures that given \( \tilde{\psi} \) as in Theorem 2.5 (b) we have \( R\tilde{\psi} \in \mathcal{B} \). This is needed to verify the abstract assumptions of Theorem 8.2(b) for \( \tilde{\psi} \) as in Theorem 2.5(b).

**Lemma A.5.** For \( 0 < \kappa < \beta \) and \( \xi : Y \to \mathbb{R} \) piecewise \( C^1 \), define
\[
\|\xi\|_0 := \sup_{j \geq 1} \frac{1}{j^k} \left( \|\xi 1_{Y_j}\|_{\mathcal{B}_w} + \frac{1}{j^{1+\beta}} \|\xi 1_{Y_j}\|_u \right)
\]
and the Banach space \( \mathcal{B}_0 = \{ \xi : Y \to \mathbb{R} : \xi \text{ is piecewise } C^1 \text{ and } \|\xi\|_0 < \infty \} \). Then \( R(\mathcal{B}_0) \subset \mathcal{B} \).

**Proof.** Recall that, by Proposition 2.2 and Lemma 2.3, \( r = O(\tau) \) and vice versa. Abbreviate \( Y_j = \{ r = j \} \); for large \( j \) these are strips close to the stable manifold \( W^s \) of the neutral fixed point, and bounded by stable and unstable curves and both \( F^{-1} \) and \( |DF|^{-1} \) are \( C^1 \) on each \( F(Y_j) \).

For the stable norm \( \| \|_s \), choose an arbitrary stable leaf \( W \) and \( q \)-Hölder function \( \varphi \in C^q(W) \) with \( |\varphi|_{C^q(W)} \leq 1 \). Let \( W_j = F^{-1}(W) \cap Y_j \). By Lemma A.2, and the fact that \( K^u \ll j^{-(1+\beta)} \) and \( |\varphi \circ F|_{C^1} \ll |\varphi|_{C^1} \) on each \( W_j \), we have
\[
\int_W R\xi \varphi d\mu^s = \sum_j \int_{W_j} \xi \varphi \circ F K^u d\mu^s \ll \sum_j j^{-(1+\beta)} \int_{W_j} \xi \varphi \circ F d\mu^s \\
\ll \sum_j j^{-(1+\beta)} \|\xi 1_{Y_j}\|_{\mathcal{B}_w} \ll \sum_j j^{-1+\kappa-\beta} < \infty. \quad (A.8)
\]
The stable part \( \| \|_s \) of \( \| \|_B \) is treated in the same way.

Now for the unstable part \( \| \|_u \), let \( \varphi \) such that \( |\varphi|_{C^1(W)} \leq 1 \). Using [BT17, Equation (43)], which expresses \( \int_{W_j} h\phi dm \) in terms of the parametrisation of \( W_j \), for any nearby leaves \( W, \tilde{W} \in Y \), we define a diffeomorphism \( v : \tilde{W} \to W \) as in [BT17, Proof of Proposition 3.2 (unstable norm part)]. Let \( v_j = F^{-1} \circ v \circ F : \tilde{W}_j \to W_j \) be the corresponding bijection between the preimage leaves \( W_j, \tilde{W}_j \subset Y_j \). Then we compute,
\[
\left| \int_{W} R\xi \varphi d\mu^s - \int_{W} R\xi \varphi d\mu^s \right| \leq \sum_j \left| \int_{W_j} \xi \varphi \circ F K^u_{W_j} d\mu^s - \int_{W_j} \xi \varphi \circ F K^u_{W_j} d\mu^s \right| \\
\leq \sum_j \int_{W_j} \xi |\varphi \circ v \circ F - \varphi \circ F| K^u_{W_j} d\mu^s \\
+ \sum_j \int_{W_j} \xi |\varphi \circ F| \left| K^u_{W_j} \circ v_j - K^u_{W_j} \right| d\mu^s \\
+ \sum_j \int_{W_j} \xi |v_j - \xi| |\varphi \circ F| K^u_{W_j} d\mu^s \\
= S_1 + S_2 + S_3.
\]
Next
\[ S_1 \leq |\varphi|_{C^1} d(W, \hat{W}) \sum_j |\xi|_{W_j} \infty |K^u_{W_j}| \infty \ll \|\varphi\|_{C^1} d(W, \hat{W}), \]

because as in the first part of this proof, the sum in the above expression is bounded.

For the sum \( S_2 \), using (A.7) we split
\[
|K^u_{W_j} - K^u_{W_j} \circ v_j| = \frac{1}{J_{m_0}} \left| (h^u \sin \varphi) \circ F \circ v_j - (h^u \sin \varphi) \circ F \right| h_0^u \sin \varphi
\]
\[
+ \frac{1}{J_{m_0}} \left| J_{m_0} - 1 \right| \left| (h^u \sin \varphi) \circ F \circ v_j \right| h_0^u \sin \varphi
\]
\[
+ \frac{1}{J_{m_0}} \left| (h^u \sin \varphi) \circ F \circ v_j \right| \left| (h^u \sin \varphi) \circ v_j \right| - 1.
\]

By distortion estimate [BT17, Equation (40)], this is bounded by \( Cd(W, \hat{W}) \frac{1}{J_{m_0}} \) for some uniform distortion constant \( C > 0 \). Therefore
\[
S_2 \leq C d(W, \hat{W}) \sum_j \| \xi \|_Y_0 \|B_u \|_{\infty} \frac{1}{J_{m_0}} \ll d(W, \hat{W}) \sum_j j^\kappa j^{-(1+\beta)} < \infty
\]
as before.

Now for \( S_3 \), the weighted \( \| \|_u \) part of the norm \( \| \|_0 \) gives \( |\xi \circ v_j - \xi| \ll j^{\kappa+1+\beta} \) \( d(W_j, \hat{W}_j) \ll j^{\kappa+1+\beta} d(W, \hat{W}) L_u(Y_j) \). As in the first half of the proof, \( |K^u_{W_j}| \infty \ll j^{-(1+\beta)} \). We have \( L_u(Y_j) \ll \tau^{1+\beta} \) due to the small tail estimates (2.3), so
\[
S_3 \ll |\varphi|_{\infty} d(W, \hat{W}) \sum j^\kappa L_u(Y_j) \ll |\varphi|_{\infty} d(W, \hat{W}).
\]

Therefore \( \|R \xi\|_{B} < \infty \) and the proof is complete. \( \square \)

**Corollary A.6.** \( R(\tau^\kappa h) \in B \) for each \( 0 < \kappa < \beta \) and \( h \in B \) (in particular, (H4)(ii) holds).

Since \( C' - \hat{\psi} \sim C \tau^\kappa \), this corollary can also be used to show that \( R(\hat{\psi} h) \in B \).

**Proof.** Since \( \tau \) is the return time of a \( C^1 \) flow to a \( C^1 \) Poincaré section, it is piecewise \( C^1 \), and we know \( \tau|_{Y_j} \ll j \). Taking \( h \in B \) and \( \varphi \in C^1(W) \) for an arbitrary stable leaf \( W \subset Y_j \), we have \( \int_w R(\tau^h) \varphi d\mu^s \leq j^\kappa \int_w h \varphi d\mu^s = j^\kappa \|h\|_B, \) so \( \frac{1}{j^\kappa} \|\tau^h\|_B \ll \|h\|_B < \infty. \)

Using (2.3), we have \( \epsilon \leq \xi(y, T + 1) - \xi(y, T) \ll T^{-(1+\beta)} \) for \( T = \tau(x, y) + O(1) \) and \( \xi(y, T) \) plays the role of \( x \). By (2.4), \( x = \xi(y) \tau(x, y)^{-\beta} (1 + o(1)) \) as \( x \to 0 \), so \( \epsilon \ll \frac{1}{x^{\beta}} \). Using (2.4) again, we can estimate that as \( \tau = \tau(x) \to \infty \) (so as \( x \to 0 \) and \( \epsilon = o(x) \)),
Let $W, \tilde{W}$ nearby stable leaves in $Y_j$ with $\varepsilon = d(W, \tilde{W})$ and $v : \tilde{W} \to W$ a diffeomorphism. Then, for $\varphi \in C^1(W), \tilde{\varphi} \in C^1(\tilde{W})$ with $d(\varphi, \tilde{\varphi}) \leq d(W, \tilde{W})$,

$$\int_{\tilde{W}} \tau^k h \tilde{\varphi} \, d\mu^s \leq \int_{W} \tau^k h \varphi \, d\mu^s$$

$$\ll \int_{\tilde{W}} |\tau^k - \tau^k \circ v_j| h \varphi \, d\mu^s + j^k \left( \int_{\tilde{W}} h \tilde{\varphi} \, d\mu^s - \int_{W} h \varphi \, d\mu^s \right)$$

$$\ll j^{k+\beta} \|h\|_{B_w} + j^k \|h\|_u.$$

Therefore $\frac{1}{j^{k+\beta}} \|\tau^k h\|_u \ll \|h\|_{B_w} < \infty$, showing that $\tau^k h \in B_0$. Combined with Lemma A.5, the result follows. \qed

As in the statement of Proposition 5.1 (ii) and Proposition 5.7 we need

**Corollary A.7.** $\bar{\tau} := \tau - \tau^*$ cannot be written as $h \circ F - h$ for any $h \in B$.

**Proof.** By Corollary A.6, $R \bar{\tau} \in B$. Because $\tau(z) \to \infty \quad \text{as} \quad z \to W^s(p), z \in F^{-1}(P_0) \setminus P_0$, we have $\sup_{w \in Y^s} \int_{W} \bar{\tau} \, d\mu^s = \infty$. Therefore $\bar{\tau} \notin B_w$ and hence $\bar{\tau}$ is not a coboundary. \qed

**A.4. Verifying (H7).** Extending the inequality $|1 - e^{-x}| \leq x^\gamma$ for all $\gamma \in (0, 1]$ and $x \geq 0$, we can find $C_\gamma$ depending only on $s \sup_a \bar{\psi}$ such that

$$|e^{-ur+s\bar{\psi}} - 1|_{1,a} \leq C_\gamma (ur + s\psi_0)^\gamma \leq C_\gamma \left( u^\gamma \sup_a \tau^\gamma + s^\gamma \sup_a \psi_0^\gamma \right) .$$

Therefore, for each $h \in B$, and $\varphi \in C^1(W), W \in Y^s$,

$$\int_{W} \left( e^{-ur+s\bar{\psi}} - 1 \right)_{1,a} h \varphi \, d\mu^s \leq C_\gamma \left( u^\gamma \sup_a \tau^\gamma + s^\gamma \sup_a \psi_0^\gamma \right) \int_{W} h \varphi \, d\mu^s ,$$

so (H7) follows for $C_2 = C_3 = C_\gamma$.

**A.5. Verifying (H6) (and thus, (H3)).** In this section we verify (H6) for $\kappa > 1/\beta$.

**Proposition A.8.** Assume that $\bar{\psi}$ satisfies (H5) and let $\hat{R}(u, s)v = R(e^{-ur}e^{s\bar{\psi}} v)$. Then there exists $\sigma_1 \in (0, 1)$ and $\delta, C_0, C_1 > 0$ such that for all $h \in B$, $n \in \mathbb{N}$, $0 \leq s < \delta$, and $u \geq 0$,

$$\|\hat{R}(u, s)^n h\|_{B_w} \leq C_1 e^{-\sigma n} \|h\|_{B_w} , \quad \|\hat{R}(u, s)^n h\|_{B} \leq C_1 e^{-\sigma n} (C_0 \sigma_1^{-n} \|h\|_{B} + C_1 \|h\|_{B_w}) .$$

Before turning to the proof, we need another lemma (which we will apply with $g \equiv 1$, but the general $g$ is needed for the induction in the proof).
Lemma A.9. Assume that $\tilde{\psi}$ satisfies (H5) (in particular, $\tilde{\psi} < C' - C^{-1} \tau^K < \infty$ for some $C', C > 0$ and $\kappa > 1/\beta$). There exists $N \in \mathbb{N}$ depending only of $F : Y \to Y$ such that for all positive integrable functions $g$ that are bounded and bounded away from zero, the following holds. There exist $\delta > 0$ such that for all $s \in [0, \delta]$, all admissible stable leaves $W \subset Y$ and all $n \in \mathbb{N}$,

$$\sum_{W' \text{ component of } F^{-n}(W)} \int_{W'} e^{s \tilde{\psi}} g \circ F^n K^{u}_W, F^n d\mu^s \leq e^{s N} \sup_{\tilde{\psi}} \int_{W} g d\mu^s,$$

where $K^{u}_W, F^n$ equals the analogue of $K^{u}_W$ from (A.7) for the iterate $F^n$ on the preimage leaf $W'$.

Proof. Let $P_1$ be the partition element containing the images $F \{(r = k)\}$ of the strips $\{r = k\}_{k \geq 2}$, see Fig. 3. Let $N \in \mathbb{N}$ be such that $F^{-N-1}(P_1)$ intersects each $P_i, i \geq 1$. Let $W$ be an arbitrary stable leaf in $P_i$ for some $i \geq 1$, and let $\mathcal{W}$ be the collection of preimage leaves under $F^{-N}$. By a change of coordinates,

$$\sum_{W' \in \mathcal{W}} \int_{W'} g \circ F^N K^{u}_W, F^N d\mu^s = \int_{W} g d\mu^s$$

for any integrable function $g$.

Given $a \geq 1$ to be chosen later, set $\mathcal{W}^+ = \{W' \in \mathcal{W} : \inf_{W'} \tau^K \geq 2NaC \sup \tilde{\psi}\}$ and $\mathcal{W}^- = \mathcal{W}\setminus \mathcal{W}^+$. Then there is $\epsilon > 0$ (depending only on the geometry of the Markov map $F$ and $\sup_{m \in \mathcal{M}} g$) such that $\sum_{W' \in \mathcal{W}^+} \int_{W'} g \circ F^N K^{u}_W, F^N d\mu^s \geq \epsilon \int_{W} g d\mu^s$. Since $\int_{W} d\mu^s$ is proportional to the measure of the element in $\bigvee_{i=0}^{N-1} F^{-i}(P)$ that $W'$ belongs to,

Proposition 2.4 gives $\epsilon \gg \mu_{\phi}((\tau > (2NaC \sup \tilde{\psi})^2)) \gg Ba\frac{1}{\beta}$ for some $B > 0$ and $\beta' := \kappa \beta > 1$. We have $\tilde{\psi}_N \leq (N - 1) \sup \tilde{\psi} - C^{-1} \tau^K \leq (N - 1 - 2Na) \sup \tilde{\psi} \leq -Na \sup \tilde{\psi}$ on $\mathcal{W}^+$, and $\tilde{\psi}_N \leq N \sup \tilde{\psi}$ on $\mathcal{W}^-$. Therefore

$$\sum_{W' \in \mathcal{W}^+} \int_{W'} e^{s \tilde{\psi}} g \circ F^N K^{u}_W, F^N d\mu^s \leq \sum_{W' \in \mathcal{W}^+} \int_{W'} e^{-s Na \sup \tilde{\psi}} g \circ F^N K^{u}_W, F^N d\mu^s$$

$$+ \sum_{W' \in \mathcal{W}^-} \int_{W'} e^{s \sup \tilde{\psi}} g \circ F^N K^{u}_W, F^N d\mu^s$$

$$\leq e^{-s Na \sup \tilde{\psi}} \int_{W} g d\mu^s + (1 - \epsilon) e^{s N} \sup \tilde{\psi} \int_{W} g d\mu^s$$

$$= (e^{s} + (1 - \epsilon) x) \int_{W} g d\mu^s =: b(x) \int_{W} g d\mu^s$$

for $x = e^{s N} \sup \tilde{\psi}$. Clearly $b(1) = 1$ and $b'(x) = -a e^{x-1} + (1 - \epsilon) < 0$ whenever $0 < x < (ae)^{1/1+a}$. Since $\epsilon \geq Ba\frac{1}{\beta}$, we find $b'(x) < 0$ for all $x \leq a_0 := B^{-1 \frac{1}{1+a}} a \frac{\beta'-1}{\beta'-1+a}$. Choose $a > \max\{1, B\frac{\beta'-1}{\beta'-1}\}$, so that $a_0 > 1$. This means that $b(x) \leq 1$ for all $1 \leq x \leq a_0$, i.e., for all $0 \leq s \leq \frac{\log a_0}{N \sup \tilde{\psi}}$.

Now for general $n = pN + q$ with $0 \leq q < N$, we use induction on $p$. Let $\mathcal{W}_p(W)$ be the collection of preimage leaves of $W$ under $F^{-pN}$. Assume by induction that

$$\sum_{W' \in \mathcal{W}_{p-1}(W')} \int_{W'} e^{s \tilde{\psi}(p-1)N} g \circ F^{(p-1)N} K^{u}_W, F^{(p-1)N} d\mu^s \leq \int_{W} g d\mu^s$$

for all $0 \leq s \leq \frac{\log a_0}{N \sup \tilde{\psi}}$.
for all stable leaves $W_1$ and $g$ as above. Then

$$
\sum_{W' \in W_p(W)} \int_{W'} e^{s\tilde{\psi}_p} p_N g \circ F^{pN} K_{W'}^{u} F^{pN} d\mu^g
$$

$$
\leq \sum_{W_1 \in W_1(W)} \sum_{W' \in W_{p-1}(W_1)} \int_{W'} e^{s\tilde{\psi}(p-1)N} K_{W'}^{u} F^{(p-1)N} \left( e^{s\tilde{\psi}_N} g \circ F^{N} K_{W}^{u} F^{N} \right) \circ F^{(p-1)N} d\mu^g
$$

$$
\leq \sum_{W_1 \in W_1(W)} \int_{W_1} e^{s\tilde{\psi}_N} g \circ F^{N} K_{W_1}^{u} F^{N} d\mu^g \leq \int_{W} g d\mu^g.
$$

This way we proved the lemma for all multiples of $N$. For $0 < q < N$, we get an extra factor $e^{sq \sup \tilde{\psi}}$. This proves the lemma. 

\[ \square \]

**Proof of Proposition A.8.** This proof goes as in [BT17, Proposition 3.2], but with some changes. The factor $z^n$ is to be replaced with $e^{-u\tau_n}$ where $\tau_n = \sum_{i=0}^{n-1} \tau \circ F^i$ and the factor $e^{s\tilde{\psi}_n}$ for $\psi_n = \sum_{i=0}^{n-1} \psi \circ F^i$ is dealt with using Lemma A.9. Let $W$ and $\tilde{W}$ be two stable leaves in the same partition element of $\{P_i\}_{i \geq 1}$. Since $\tau$ and $\psi$ are not constant on partition elements, we get a third and fourth term in the strong unstable norm part of [BT17, Proposition 3.2] expressing the difference of $\tau_n$ on nearby preimage leaves $\tilde{W}_j$ and $W_j = v_j(\tilde{W}_j)$ of $W$ and $\tilde{W}$:

$$
S_3 = \sum_j \left| \int_{\tilde{W}_j} h_0 \circ F^j e^{s\tilde{\psi}_n} (e^{-u\tau_n} - e^{-u(\tau_n \circ v_j)}) K_{W_j}^{u} F^j d\mu^g \right| \tag{A.10}
$$

and

$$
S_4 = \sum_j \left| \int_{\tilde{W}_j} h_0 \circ F^j e^{-u(\tau_n \circ v_j)} (e^{s\tilde{\psi}_n} - e^{s\tilde{\psi}_n \circ v_j}) K_{W_j}^{u} F^j d\mu^g \right|, \tag{A.11}
$$

for some $\tilde{\psi}$ with $|\tilde{\psi}|_{C^1(\tilde{W})} \leq 1$.

For $S_3$, without loss of generality, we can assume that $\tau_n \circ v_j \geq \tau_n$, so $|e^{-u\tau_n} - e^{-u(\tau_n \circ v_j)}| \leq u e^{-u\tau_n} |\tau_n \circ v_j - \tau_n|$. By (A.9), we have $|\tau(x + \epsilon, y) - \tau(x, y)| = \beta^{-1} \xi_0(y) \tau(x, y) \beta^{1+\beta} \epsilon (1 + o(1) + O(\frac{\epsilon}{\epsilon})).$ Applied to $\epsilon_i := d(F^i(W_j), F^i(\tilde{W}_j)) \ll \tau_i^{-\beta} \circ F^i \epsilon_i$, this gives

$$
\sum_{i=0}^{n-1} |\tau \circ F^i \circ v_j - \tau \circ F^i| \ll \sum_{i=0}^{n-1} \tau_i^{1+\beta} \circ F^i d(F^i(W_j), F^i(\tilde{W}_j))
$$

$$
\ll \sum_{i=0}^{n-1} \epsilon_{i+1} \ll \epsilon_n = d(W, \tilde{W}), \tag{A.12}
$$

and therefore $|e^{-u\tau_n} - e^{-u(\tau_n \circ v_j)}| \ll u e^{-u\tau_n} d(W, \tilde{W}).$ Combining the above with (A.10), we obtain
$$S_3 \leq u \ d(W, \tilde{W}) \sum_j \left| \int_{\tilde{W}_j} h\bar{\psi} \circ F^n e^{-u\tau_n + s} \sup \bar{\psi}_n K_{W_j}^u F^n d\mu^s \right|$$
$$\ll \|h\|_{B_w} u e^{-un} d(W, \tilde{W}) \sum_j \left| \int_{\tilde{W}_j} e^{s\bar{\psi}_n} K_{W_j}^u F^n d\mu^s \right|$$
$$\leq \|h\|_{B_w} u e^{-un} d(W, \tilde{W}) e^{sN} \sup \bar{\psi},$$

where we used that $\tau_n \geq n$, and the last step follows from Lemma A.9 with the $N$ (independent of $n, u, s$) taken from that lemma too.

For $S_4$, using (H5) and (A.9), we obtain:

$$|e^{s\bar{\psi}(x+\epsilon)} - e^{s\bar{\psi}(x)}| \ll e^{s\sup \bar{\psi}} e^{-s\tau^k/C} s^k \left( \frac{\tau(x + \epsilon, y)}{\beta} \right)$$
$$= e^{s\sup \bar{\psi}} s e^{-s\tau^k/C} \left( \frac{K}{\beta} \right) \xi_0(y) \tau^{k+1} \epsilon (1 + o(1) + O(\epsilon))$$
$$\ll e^{s\sup \bar{\psi}} s e^{-s\tau^k/C} \left( \frac{K}{\beta} \right) \xi_0(y) \tau^{k+1} \epsilon (1 + o(1) + O(\epsilon))$$

where we compute the supremum over $\tau$ to conclude that $K \leq e^{-K(CK)^{\frac{k-1}{k}} \frac{1}{s^k}}$. Apply the above with $\epsilon = \epsilon_i := d(F^i(W_j), F^i(\tilde{W}_j))$ as in (A.12). Then we can estimate $S_4$ in the same way as $S_3$:

$$S_4 \leq s^{\frac{1}{k}} d(W, \tilde{W}) \sum_j \left| \int_{\tilde{W}_j} h\bar{\psi} \circ F^n e^{-u\tau_n + s} \sup \bar{\psi}_n K_{W_j}^u F^n d\mu^s \right|$$
$$\ll \|h\|_{B_w} e^{-un} e^{sN} \sup \bar{\psi} \frac{1}{s^{\frac{1}{k}}} d(W, \tilde{W}).$$
