ABSTRACT

Deep learning approaches in image processing predominantly resort to supervised learning. A majority of methods for image denoising are no exception to this rule and hence demand pairs of noisy and corresponding clean images. Only recently has there been the emergence of methods such as Noise2Void, where a deep neural network learns to denoise solely from noisy images. However, when clean images that do not directly correspond to any of the noisy images are actually available, there is room for improvement as these clean images contain useful information that fully unsupervised methods do not exploit. In this paper, we propose a method for image denoising in this setting. First, we use a flow-based generative model to learn a prior from clean images. We then use it to train a denoising network without the need for any clean targets. We demonstrate the efficacy of our method through extensive experiments and comparisons.

Index Terms— image denoising, flow-based models, unsupervised methods

1. INTRODUCTION

Noise corrupts virtually any image captured through a camera. The degradation due to noise is typically captured in the equation: $Y = X + N$ where $X$ is a clean image, $N$ is noise and $Y$ is the corresponding noisy version of $X$. Image denoising methods attempt to recover the clean image from its noisy version.

Traditional methods such as BM3D [1], NSCR [2], WNNM [3] rely on the self-similarity of image patches to denoise solely from noisy images. Methods such as [4, 5, 6] that use deep learning have been proposed for image denoising. Although they achieve state-of-the-art performance along with excellent test times, they are all discriminative models. As a result, they require pairs of noisy images and their corresponding clean images.

Recently, deep learning methods like Noise2Noise [7] and Noise2Void [8] have been proposed that use statistical properties of noisy image patches to eliminate noise. While these methods do not need any clean images, in situations where they are available, they cannot utilize the valuable information available in the clean images.

Another important class of methods are prior based. Priors are crucial for obtaining a reasonable answer out of all the possible solutions for an ill-posed problem such as image denoising. With handcrafted priors, these methods can be used when clean images are not available. However, these priors have been criticized as they are often chosen for their computational or analytical convenience rather than accuracy. Deep learning has allowed for constructing more accurate priors.

Deep image prior [10] claims that the architecture of a convolutional neural network alone can act as a prior for natural images. Though the results are good, it is surprising as there is no mathematical justification for why this prior works. Going further, Chen et al [11] have used a GAN [12] to explicitly construct a prior for realistic noise which they use for denoising.

In this paper, we propose an approach for denoising using another class of generative models, called flow-based generative models [13, 14]. These models learn an invertible transformation from a complex distribution like images to a simple one like the Gaussian distribution. They have been successfully used to generate realistic images. An example of this is the work by Kingma et al., in [15] where they use flow-based models to generate photorealistic face images using the CelebA HQ dataset [16]. Unlike GANs, Flow-based models can explicitly and accurately capture the likelihood function of clean images. As a consequence, they are excellent candidates for learning a realistic prior which is essential for superior denoising performance. Also, they do not suffer from the unstable training dynamics that GANs are notorious for.

Figure 1 shows a sample result from our method. We train a
Flow-based generative models [13, 14] learn the bijective transformation from clean images to the standard multivariate Gaussian random variable. Due to structure of the flow-based model as described in (2) and the tractable probability density of a Gaussian random variable, we can evaluate (6) for any given image and obtain the likelihood that the image is clean. Concretely, we train a flow-based model $h$ to minimize the

$$
\text{log } P(x) = \log P(z) - \sum_{i=1}^{n} \log \left| \frac{dh}{dx} \right|
$$

where $x, y$ are the inputs and outputs of the layer respectively; $p_1, p_2$ is a partition of the features along the channel dimension and $m$ is an arbitrary transformation. For this layer, it is easy to see that the Jacobian is

$$
\begin{bmatrix}
I_{p_1} & 0 \\
\frac{d \text{log } P(x_{p_1})}{d x_{p_1}} & I_{p_2}
\end{bmatrix}
$$

where $I_{p_1}, I_{p_2}$ are identity matrices that are of the same size as the partitions $p_1, p_2$. Conveniently, the determinant of the matrix in (9) is simply 1 and hence it is ideal for use in a flow-based model. Unlike in [13, 14, 15], we do not require invertible transformations as there is no need for sampling when we are only learning a prior. Nevertheless, in our work we use the layers and formulation of flow-based models proposed in [15].

3. PROPOSED METHOD

In this section we describe our two-stage approach (illustrated in Figure 2) to using the log-likelihood in (6) as a prior for image denoising.

In the first stage, we train a flow-based model to learn a prior distribution on clean images. Next, we use this prior along with weak supervision (see subsection 3.2) to train a denoising network.

3.1. Stage 1: Training the Flow model

First, we train a flow-based model based on clean images to learn a transformation from clean images to the standard multivariate Gaussian random variable. Due to structure of the flow-based model as described in (2) and the tractable probability density of a Gaussian random variable, we can evaluate (6) for any given image and obtain the likelihood that the image is clean.

Concretely, we train a flow-based model $h$ to minimize the
Following objective:

\[- \log P(X) = - \log P(Z) + \sum_{i=1}^{n} \log \left| \frac{\partial Z_i}{\partial Z_{i-1}} \right| \] \hfill (10)

\[= \frac{1}{2} \| Z \|_2^2 + \sum_{i=1}^{n} \log \left| \frac{\partial Z_i}{\partial Z_{i-1}} \right| + C \] \hfill (11)

where \(C\) is a constant that normalizes the Gaussian distribution. It has no bearing on the training and hence can be eliminated. Note that once the training in Stage 1 is complete, \(h\) is fixed during Stage 2.

### 3.2. Stage 2: Training the Denoiser

Given a noisy image \(Y\), the posterior distribution for the corresponding clean image \(X\) is

\[P(X \mid Y) = \frac{P(Y \mid X)P(X)}{P(Y)} \] \hfill (12)

To obtain the maximum a posteriori (MAP) estimate of the clean image, the denominator can be ignored and the numerator or equivalently its log value is maximized.

\[\arg \max_{X} \log P(X \mid Y) = \arg \max_{X} \log P(Y \mid X) + \log P(X) \] \hfill (13)

Assuming additive white Gaussian noise, \(\log P(Y \mid X)\) is simply the negative of the squared error between \(Y\) and \(X\). Using the flow model \(h\) trained in Stage 1, we can also compute the prior log-likelihood of \(X\). Based on (13), we can formulate a loss function (note the change of signs as by convention, we want to minimize this loss) for the denoiser \(d\) as follows:

\[(Y - X)^2 - \lambda \log P(X) \] \hfill (14)

where \(\lambda\) is a hyperparameter that controls the relative importance of the conditional and the prior probability distributions. To be mathematically precise, \(\lambda\) depends on the noise level in the image. From our experiments, we also find that the performance of the denoiser is very sensitive to the choice of \(\lambda\). This poses a challenge as we want to train a single denoiser for a range of noise levels.

To reduce the dependency of \(\lambda\) on the noise level, we modify the first term in (14) to instead measure the squared error between blurred versions of \(X\) and \(Y\). Intuitively speaking, we are training \(d\) to copy only the low frequency information from the input \(Y\) while adding details that make the output \(X\) to look more clean. The flow model \(h\) dictates what details are added to \(Y\).

The final form of the loss function we use for the denoiser \(d\) is

\[(B(Y) - B(X))^2 - \lambda \log P(X) \] \hfill (15)

Here \(B\) is a local mean filter, the size of which is chosen to be \(3 \times 3\), as that gave the best performance on the validation set.

### 4. EXPERIMENTS

#### 4.1. Training Details

We use the validation set of MS COCO [17] for our training. Of the 41K images it contains, we use a subset of 20K images as our clean image dataset. We add Gaussian noise to another subset of 20K images to form our noisy image dataset. As we want our method to be agnostic to noise level, for each image, the standard deviation of the added noise is chosen uniformly in the interval \([0, 50]\). We set aside the remaining 1K images for validation to tune the hyperparameters \(\lambda\) and the size of the local mean filter.

##### 4.1.1. Stage 1

We use the architecture described in [15] for the flow-based model. We feed patches of size 32 from images in the clean dataset as input to this model. Using the loss in (11), we train for 100 epochs using the Adam optimizer [18] with learning rate \(1 \times 10^{-3}\), \(\beta_1 = 0.9\), \(\beta_2 = 0.999\).

##### 4.1.2. Stage 2

We use the ResNet [19] for our denoiser. Because the flow-based model only accepts fixed size inputs and the ResNet does not change input size, we use input patches of size 32. In this stage, however, they are extracted from noisy images. Using (15), we train only the denoiser, for 100 epochs using the Adam optimizer with the same parameter settings as in stage 1. We experimented with various choices of \(\lambda\) and the size of the local mean filter. Based on our results, we choose \(\lambda = 1.5 \times 10^{-6}\) and local mean filter of size \(3 \times 3\) as they give the best PSNR values.

#### 4.2. Results

Following [1, 8], we evaluate our method on the BSD68 dataset [9] for different noise levels and compare it with BM3D [1], Noise2Void [8], Deep image prior [10]. All comparisons are made using either results reported in the respective papers or those obtained from running the code that the authors have generously shared. Table 1 shows the average PSNR values of different methods for images from BSD68. Although PSNR is not an accurate metric for perceptual quality, our method performs competitively with Noise2Void and is better than Deep image prior.

Figure 3 shows qualitative comparison of our results with other methods. Our method is able to remove noise effectively without blurring any textures, details or sharp edges (this is obvious in the sky in the first set of images). Deep image prior produces outputs that still have visible noise. Noise2Void, although better than Deep image prior, fails in some cases. An example of this is the blades of grass in the third set of images where the output from Noise2Void is noticeably desaturated.
Fig. 3: Qualitative results. Here, we show the ground truth, the noisy input (Gaussian noise, $\sigma = 25$) and the denoised outputs from BM3D [1], Noise2Void [8], Deep image prior [10] and finally, our method. None of these methods need supervision.

| Method   | BM3D | DnCNN | N2V  | DIP  | Ours |
|----------|------|-------|------|------|------|
| $\sigma = 15$ | 33.14 | 31.73 | 28.92 | 27.58 | 29.10 |
| $\sigma = 25$ | 30.22 | 29.23 | 27.68 | 26.6  | 28.61 |
| $\sigma = 35$ | 28.25 | 28.95 | 26.51 | 25.97 | 26.2  |

Table 1: Quantitative results. We show PSNR (dB) of various denoising methods, namely, BM3D [1], DnCNN [5], Noise2Void [8], Deep image prior [10] and our method. Of these, only DnCNN is fully supervised.

5. CONCLUSIONS

We have proposed the use of flow-based model as a mathematically justifiable and realistic prior for image denoising. We have conducted qualitative and quantitative experiments on the BSD68 [9] dataset that reveals the competitive performance of our method.

Motivated by our success, we conjecture that using a flow-based model prior should be effective for solving other image restoration tasks such as image deblurring and super-resolution in an unsupervised fashion.
