A CONSTRAINT ENERGY MINIMIZING GENERALIZED MULTISCALE FINITE ELEMENT METHOD FOR PARABOLIC EQUATIONS

MENGNAN LI†, ERIC CHUNG‡, AND LIJIAN JIANG§

Abstract. In this paper, we present a Constraint Energy Minimizing Generalized Multiscale Finite Element Method (CEM-GMsFEM) for parabolic equations with multiscale coefficients, arising from applications in porous media. We will present the construction of CEM-GMsFEM and rigorously analyze its convergence for the parabolic equations. The convergence rate is characterized by the coarse grid size and the eigenvalue decay of local spectral problems, but is independent of the scale length and contrast of the media. The analysis shows that the method has a first order convergence rate with respect to coarse grid size in the energy norm and second order convergence rate with respect to coarse grid size in $L^2$ norm under some appropriate assumptions. For the temporal discretization, finite difference techniques are used and the convergence analysis of full discrete scheme is given. Moreover, a posteriori error estimator is derived and analyzed. A few numerical results for porous media applications are presented to confirm the theoretical findings and demonstrate the performance of the approach.

Key words. multiscale parabolic equations, CEM-GMsFEM, high-contrast porous media, a posteriori error estimator

1. Introduction. The multiscale characteristic of formation properties pose significant challenges for subsurface flow modeling. Geological characterizations that capture these effects are typically developed at scales that are too fine for direct flow simulation, so reduced models are necessary to compute the solution of flow problems in practice. There are a number of methods that have been developed to solve multiscale problems. The upscaling method [7, 25] is one of the classical approaches, which is based on the homogenization theory (e.g., [3, 6, 8, 20]). The key to upscaling techniques is to form a coarse-scale equation using pre-computed effective coefficients [26]. The multiscale finite element method (MsFEM) [13] share similarities with upscaling methods, but the coarse-scale equations are obtained through variational formulation by multiscale basis functions, which contain fine scale information. Some other multiscale methods such as variational multiscale methods [14, 2] and multi-scale finite volume method [15] share the model reduction techniques but using different frameworks to solve multiscale problems.

Recently a multiscale method [5] for which the basis functions are constructed by the principle of constraint energy minimization is proposed. The approach shares some ideas of the generalized multiscale finite element method (GMsFEM) [9, 4, 17], which is a systematic way to find the multiscale basis functions. In particular, the GMsFEM constructs a suitable local snapshot space and then solve a spectral problem in each coarse block. The basis functions are the dominant eigenvectors corresponding

to small eigenvalues. The GMsFEM’s convergence depends on the eigenvalue decay of the local spectral problems \[9\]. To obtain a convergence depending on the coarse mesh, a new methodology, called constraint energy minimizing GMsFEM (CEM-GMsFEM), is proposed in \[5\]. The idea of CEM-GMsFEM can be divided in two steps. First, this method is to construct auxiliary basis functions via local spectral problems. Then, constraint energy minimization problems are solved to obtain the required basis functions, where the constraints are related to the auxiliary basis functions. Combining the eigenfunctions and the energy minimizing properties, the basis functions are shown to have exponential decay away from the target coarse block, and thus the basis functions can be computed locally. In addition, the convergence depends on the coarse mesh size when the oversampling domain is carefully chosen. Also, the size of oversampling domain depends weakly on the contrast of the media.

There are some multiscale methods to solve the parabolic equations with multiscale coefficients \[16, 20, 12, 23\]. These methods can get accurate solutions in some cases, but one may need to use multiple multiscale basis functions which can be computed locally in order to accurately capture complex multiscale features. The aim of this paper is to solve these problems by CEM-GMsFEM and carry out convergence analysis for parabolic equations with high-contrast coefficients. The multiscale basis functions allow a spatial decay and can be used in models with the similar multiscale coefficients and different source terms, boundary conditions and initial conditions. The convergence analysis of the semidiscrete formulation is made first. We use an elliptic spectral projection as the bridge between the multiscale finite element space and the continuous space. Then, we show that the method is first order convergence rate with respect to coarse grid size in the energy norm, and second order convergence rate with respect coarse grid size in the \(L^2\) norm, under some mild assumptions on the solutions of parabolic equations. In addition, we also consider the fully discrete scheme, and prove its stability and convergence. Furthermore, we derive an a posteriori error bound for the CEM-GMsFEM scheme, which can be served as a foundation for adaptive enrichment schemes \[1, 18, 21, 22, 24\]. We prove that the error between the multiscale finite element solution and the fine-scale solution is bounded by a local error indicator.

We consider two versions of CEM-GMsFEM. The first one is based on the constraint energy minimization and the second one is based on the relax version by solving unconstrained energy minimization. We present the numerical results using the heterogeneous permeability fields with channels and inclusions. By selecting the number of basis functions and oversampling layers properly, the numerical results can verify our theoretical estimates and convergence rate. In subsurface problems, the model with a fracture structure is of importance. The permeability in fractures is very different from that in the surrounding matrix. And the discrete fracture model (DFM) is one of the important fracture models and has been extensively studied \[10, 11, 19\]. In the numerical result section, we apply the CEM-GMsFEM to DFM in a single phase flow. The numerical results of a posteriori error bound is also given and show the robustness of the a posteriori error estimator.

This paper is organized as follows. In Section 2, we will give some preliminaries. In Section 3, basis functions of CEM-GMsFEM are presented. In Section 4, we make the convergence analysis of the semi-discrete formulation. In Section 5, the analysis of the fully discrete scheme is presented. In Section 6, a few numerical results are presented to confirm the convergence analysis. Finally, some conclusions are given.
2. Preliminaries. Let $\Omega$ be a bounded computational domain in $\mathbb{R}^d$ ($d = 2, 3$) and $T > 0$ be a fixed time. We consider the following model parabolic equation

$$
\begin{align*}
\begin{cases}
\quad u_t - \nabla \cdot (\kappa(x) \nabla u) = f(x, t) & \text{in } \Omega \times (0, T], \\
\quad u = 0 & \text{on } \partial \Omega \times (0, T], \\
\quad u(\cdot, 0) = u_0(x) & \text{in } \Omega.
\end{cases}
\end{align*}
$$

We assume that multiscale coefficient $\kappa(x)$ is uniformly positive and bound in $\Omega$, i.e., there exists $0 < \kappa_0 < \kappa_1 < \infty$ such that $\kappa_0 \leq \kappa(x) \leq \kappa_1$, but the ratio $\kappa_1/\kappa_0$ can be large. This parabolic model is often used in the subsurface flow modeling. We give the notions of fine grid and coarse grid for the domain $\Omega$. Let $H$ be the coarse-mesh size and $\mathcal{T}_h$ a finite element conforming coarse partition of the domain $\Omega$. Each coarse grid block in $\mathcal{T}_h$ is a connected union of fine grid blocks in the fine partition $\mathcal{T}_h$, where $h$ denotes the fine grid size. Let $N_c$ be the number of coarse vertices and $N$ the number of elements of $\mathcal{T}_h$. Let $\{x_i\}_{i=1}^{N_c}$ be the set of vertices in $\mathcal{T}_h$ and $\omega_i = \bigcup\{K_j \in \mathcal{T}_h | x_i \in K_j\}$ the neighborhood of the node $x_i$. Figure 2.1 illustrates the fine grid, coarse grid $K_i$, the neighborhood $\omega_i$ and oversampling domain $K_{i,1}$ obtained using one coarse element layer extension. In this paper, we use the usual notations (e.g., $H^1(\Omega)$) for standard Sobolev spaces. We also use the conventional notations such as $L^2(0, T; H^1(\Omega))$ for space-time dependent Sobolev spaces. For simplicity of notations, we will suppress the time variable $t$ and the space variable $x$ in functions when no ambiguity occurs.

Let $V := H^1(\Omega)$ and $V_0 := H^1_0(\Omega)$. The weak formulation of (2.1) is to find $u(\cdot, t) \in V_0$ such that

$$
\begin{align*}
\begin{cases}
\quad (u_t, v) + a(u, v) = (f, v) & \forall v \in V_0, \ t > 0, \\
\quad (u(\cdot, 0), v) = (u_0, v) & \forall v \in V_0,
\end{cases}
\end{align*}
$$

where

$$
a(u, v) = \int_{\Omega} \kappa \nabla u \cdot \nabla v, \quad (f, v) = \int_{\Omega} f v.
$$

The aim of this paper is to construct a multiscale method for (2.1). To this end, we will construct a finite dimensional multiscale space $V_{ms} \subset V_0$, whose dimension is
small. Then we will find the multiscale solution \( u(\cdot, t) \in V_{ms} \) by solving

\[
\begin{aligned}
((u_{ms})_t, v) + a(u_{ms}, v) &= (f, v) \quad \forall v \in V_{ms}, \ t > 0 \\
(u_{ms}(\cdot, 0), v) &= (u_0, v) \quad \forall v \in V_{ms}.
\end{aligned}
\]

(2.3)

We denote \( u_{0,ms} \in V_{ms} \) as the \( L^2 \) projection of \( u_0 \) onto \( V_{ms} \).

3. Construction of CEM-GMsFEM basis functions. In this section, we briefly describe the construction of CEM-GMsFEM basis functions. This process can be divided into two stages. The first stage is the construction of the auxiliary space by solving a local spectral problem in each coarse element \( K \). The second stage is to construct the multiscale basis functions by solving some local constraint energy minimization problems in oversampling domains.

3.1. Auxiliary basis function. In this subsection, we present how to construct the auxiliary space. Let \( V(K_i) = H^1(K_i) \) for a generic coarse block \( K_i \). We solve the following spectral problem in each coarse element \( K_i \): find eigen-pairs \( \{ \lambda^{(i)}_j, \phi^{(i)}_j \} \) such that

\[
a_i(\phi^{(i)}_j, v) = \lambda^{(i)}_j s_i(\phi^{(i)}_j, v) \quad \forall v \in V(K_i),
\]

where

\[
a_i(u, v) = \int_{K_i} \kappa \nabla u \cdot \nabla v, \quad s_i(u, v) = \int_{K_i} \tilde{\kappa} uv.
\]

Here \( \tilde{\kappa} = \kappa \sum_{j=1}^{N_c} |\nabla \chi_j|^2 \) and \( \{ \chi_j \} \) is a set of partition of unity functions for the coarse partition \( T^H \). We assume that the eigenfunctions satisfy the normalized condition \( s_i(\phi^{(i)}_j, \phi^{(i)}_j) = 1 \). Let the eigenvalues \( \lambda^{(i)}_j \) be arranged in ascending order, i.e., \( \lambda^{(i)}_1 \leq \lambda^{(i)}_2 \leq \cdots \). We define the local auxiliary multiscale space \( V^{(i)}_{aux} \) by using the first \( L_i \) eigenfunctions

\[
V^{(i)}_{aux} = \text{span}\{ \phi^{(i)}_j | 1 \leq j \leq L_i \}.
\]

Then the global auxiliary space \( V_{aux} \) is defined by using these local auxiliary spaces, i.e.,

\[
V_{aux} = \bigoplus_{i=1}^{N} V^{(i)}_{aux}.
\]

To construct the CEM-GMsFEM basis functions, we need the following definition.

**Definition 3.1.** \((\phi^{(i)}_j\text{-orthogonality})\) Given a function \( \phi^{(i)}_j \in V_{aux} \), if a function \( \psi \in V \) satisfies

\[
s(\psi, \phi^{(i)}_j) = 1, \quad s(\psi, \phi^{(i')}_j) = 0 \quad \text{if} \ j' \neq j \text{ or} \ i' \neq i,
\]

then we say that \( \psi \) is \( \phi^{(i)}_j \)-orthogonal. Where \( s(u, v) = \sum_{i=1}^{N} s_{i}(u,v) \).

We define an operator \( \pi : V \to V_{aux} \) by

\[
\pi(v) = \sum_{i=1}^{N} \sum_{j=1}^{L_i} s_{i}(v, \phi^{(i)}_j) \phi^{(i)}_j, \quad \forall v \in V.
\]

The null space of the operator \( \pi \) is defined by \( \tilde{V} = \{ v \in V | \pi(v) = 0 \} \).
3.2. Multiscale basis functions in CEM-GMsFEM. Now we present the construction of the multiscale basis functions. Given a coarse block $K_i$, we denote the oversampling region $K_{i,m} \subset \Omega$ obtained by enlarging $K_i$ with $m$ coarse grid layers (see Figure 2.1). Let $V_0(K_{i,m}) := H^1_0(K_{i,m})$. Then, we define the multiscale basis function $\psi_{j,ms}^{(i)} \in V_0(K_{i,m})$ by

$$\psi_{j,ms}^{(i)} = \arg\min \{a(\psi, \psi)|\psi \in V_0(K_{i,m}), \psi \text{ is } \phi_j^{(i)}\text{-orthogonal}\}. \quad (3.1)$$

Then the CEM-GMsFEM space is defined by

$$V_{ms} = \text{span}\{\psi_{j,ms}^{(i)}|1 \leq j \leq L_i, 1 \leq i \leq N\}. \quad (3.2)$$

By using Lagrange Multiplier, the problem (3.1) can be rewritten as the following problem: find $\psi_{j,ms}^{(i)} \in V_0(K_{i,m})$, $\lambda \in V_{aux}^{(i)}(K_{i,m})$ such that

$$\begin{cases}
a(\psi_{j,ms}^{(i)}, \omega) + s(\omega, \lambda) = 0 & \forall \omega \in V_0(K_{i,m}), \\
s(\psi_{j,ms}^{(i)} - \phi_j^{(i)}, \nu) = 0 & \forall \nu \in V_{aux}^{(i)}(K_{i,m}),
\end{cases}$$

where $V_{aux}(K_{i,m})$ is the union of all local auxiliary spaces for $K_j \subset K_{i,m}$.

By [5], we can relax the $\phi_j^{(i)}$-orthogonality in (3.1) and get a relaxed CEM-GMsFEM. This can be achieved by solving the unconstrained minimization problem: find $\psi_{j,rms}^{(i)} \in V_0(K_{i,m})$ such that

$$\psi_{j,rms}^{(i)} = \arg\min \{a(\psi, \psi) + s(\pi\psi - \phi_j^{(i)}, \pi\psi - \phi_j^{(i)})|\psi \in V_0(K_{i,m})\}. \quad (3.2)$$

Then the resulting multiscale finite element space is defined by

$$V_{rms} = \{\psi_{j,rms}^{(i)}|1 \leq j \leq L_i, 1 \leq i \leq N\}.$$ 

We note that (3.2) is equivalent to

$$a(\psi_{j,rms}^{(i)}, \omega) + s(\pi\psi_{j,rms}^{(i)} - \phi_j^{(i)}, \pi\omega) = 0, \forall \omega \in V_0(K_{i,m}).$$

4. The Semidiscrete formulation. In this section, we approximate the solution $u(x,t)$ of the parabolic problem (2.2) by a function $u_{ms}$ which belongs to the space $V_{ms}$ for each $t > 0$. The solution $u_{ms}$ solves equation (2.3). We define the following norms for our analysis:

$$\|u\|_{a}^2 := \int_{\Omega} \kappa |\nabla u|^2, \quad \|u\|_{s}^2 := \int_{\Omega} \bar{\kappa} |u|^2.$$ 

4.1. Error estimates. In this subsection, we will give the error estimates of the proposed method. To this end, we need some preliminary lemmas.

Let $\hat{u} \in V_{ms}$ be the elliptic projection of the function $u \in V$, i.e., $\hat{u}$ satisfies

$$a(u - \hat{u}, v) = 0 \forall v \in V_{ms}. \quad (3.3)$$

The following lemma gives an estimate between the solution of elliptic equation and its elliptic projection.
Lemma 4.1. Let $u$ be the solution of the elliptic equation
\[
\begin{cases}
-\text{div}(\kappa \nabla u) = f & \text{in } \Omega \\
u = 0 & \text{on } \partial \Omega,
\end{cases}
\tag{4.1}
\]
and $\hat{u} \in V_{ms}$ be the elliptic projection of the $u$ in the subspace of $V_{ms}$. If $\{\chi_j\}$ are the bilinear partition of unity functions and $m = O(\log(\frac{\kappa_{max}}{\kappa_{min}}))$, where $m$ is the number of oversampling layers in the construction of basis in (3.1). Then
\[
\|u - \hat{u}\|_a \leq CH \Lambda^{-\frac{1}{2}}\|\kappa^{-\frac{1}{2}}f\|,
\tag{4.2}
\]
where $\Lambda = \min_{1 \leq i \leq N} \lambda^{(j)}_{L_{i+1}}$.

The following lemma gives a regularity estimate for the solution of the parabolic equation (2.1).

Lemma 4.2. Let $u$ be the solution of the parabolic equation (2.1). Then
\[
\|u_t\|_{L^2(0,T;L^2(\Omega))} \leq C \left( \|u_0\|_a^2 + \|f\|_{L^2(0,T;L^2(\Omega))}^2 \right).
\tag{4.3}
\]

Proof. By (2.1), we have
\[
(u_t, u_t) + a(u, u_t) = (f, u_t),
\]
which implies
\[
\|u_t\|^2 + \frac{1}{2} \frac{d}{dt} \|u\|^2 = (f, u_t).
\]
Integrating with respect to time, we have
\[
\int_0^T \|u_t\|^2 + \frac{1}{2} \|u\|^2 = \int_0^T (f, u_t) + \frac{1}{2} \|u_0\|^2.
\]
This completes the proof.

To estimate the error bound, the elliptic projection $\hat{u} \in V_{ms}$ of the solution $u$ plays an important role. The following lemma gives the error estimate of $\hat{u}(t)$ for the parabolic equation.

Lemma 4.3. Let $u$ be the solution of (2.2). For each $t > 0$, we define the elliptic projection $\hat{u}(t) \in V_{ms}$ by
\[
a(u(t) - \hat{u}(t), v) = 0, \quad \forall v \in V_{ms}.
\tag{4.4}
\]
Then, for any $t > 0$,
\[
\|(u - \hat{u})(t)\|_a \leq CH \Lambda^{-\frac{1}{2}}\|\kappa^{-\frac{1}{2}}(f - u_t)(t)\|,
\tag{4.5}
\]
\[
\|(u - \hat{u})(t)\| \leq CH^2 \Lambda^{-1}\kappa_0^{-\frac{1}{2}}\|\kappa^{-\frac{1}{2}}(f - u_t)(t)\|,
\tag{4.6}
\]
where $C$ is a constant independent of $\kappa$ and the mesh size $H$.

Proof. Note that the solution $u \in V_0$ of (2.2) satisfies
\[
a(u,v) = (f - u_t, v), \quad \forall v \in V_0, \forall t > 0.
\]
Thus, $\hat{u}(t) \in V_{ms}$ satisfies

$$a(\hat{u}, v) = a(u, v) = (f - u_t, v), \quad \forall v \in V_{ms}, \forall t > 0.$$  

By Lemma 4.1, we obtain

$$\|u - \hat{u}\|_a \leq C H A^{-1} \kappa^{-\frac{1}{2}} (f - u_t), \quad \forall t > 0.$$  

Next, we derive the error estimate in the $L^2$ norm. We will apply the Aubin-Nitsche lift technique. For each $t > 0$, we define $w \in V_0$ by

$$a(w, v) = a(u - \hat{u}, v), \quad \forall v \in V_0,$$

and define $\hat{w}$ as the elliptic projection of $w$ in the space $V_{ms}$, that is,

$$a(\hat{w}, v) = a(u - \hat{u}, v), \quad \forall v \in V_{ms}.$$  

By Lemma 4.1, we obtain

$$\|u - \hat{u}\|^2 = a(w, u - \hat{u}) = a(w - \hat{w}, u - \hat{u}) \leq \|w - \hat{w}\|_a \|u - \hat{u}\|_a \leq C (H A^{-1} \kappa^{-\frac{1}{2}}) \|u - \hat{u}\| (H A^{-1} \kappa^{-\frac{1}{2}} (f - u_t))$$

where the second equality is obtained by (4.4). Hence, we have

$$\|u - \hat{u}\| \leq C H A^{-1} \kappa^{-\frac{1}{2}} \kappa^{-\frac{1}{2}} (f - u_t), \quad \forall t > 0.$$  

This completes the proof. □

In the following theorems, we will prove the error estimates in the $L^2$ norm and energy norm. We will first state and prove the estimate in energy norm.

**Theorem 4.4.** Let $u$ and $u_{ms}$ be the solution of (2.2) and (2.3), respectively. Then

$$\|(u - u_{ms})(\cdot, T)\|^2 + \int_0^T \|u - u_{ms}\|^2_a \leq C H^2 A^{-1} \kappa_0^{-\frac{1}{2}} \|u - u_{ms}\|_{L^2(0,T;L^2(\Omega))}^2 \left(\|u_0\|_a^2 + \|u_{0,ms}\|_a^2 + \|f\|_{L^2(0,T;L^2(\Omega))}^2\right)^{\frac{1}{2}}$$

$$+ C H^2 A^{-1} \kappa^{-\frac{1}{2}} (f - u_t)_{L^2(0,T;L^2(\Omega))}$$

(4.7)

where $C$ is a constant independent of $\kappa$ and the mesh size $H$.

**Proof.** By (2.2) and (2.3), we have

$$(u - u_{ms})_t, v + a(u - u_{ms}, v) = 0$$

for all $v \in V_{ms}$. We define $\hat{u} \in V_{ms}$ as the elliptic projection of $u$, which satisfies (4.5) and (4.6). Taking $v = \hat{u} - u_{ms}$, we have the following equation

$$(u - u_{ms})_t, (\hat{u} - u_{ms}) + a(u - u_{ms}, (\hat{u} - u_{ms}) = 0.$$
This can be written as 
\[(u - u_{ms})_t, u - u_{ms}) + a(u - u_{ms}, u - u_{ms}) = ((u - u_{ms})_t, u - \hat{\alpha}) + a(u - u_{ms}, u - \hat{\alpha}).\]

This implies 
\[
\frac{1}{2} \frac{d}{dt} \| u - u_{ms} \|^2 + \| u - u_{ms} \|^2_a = ((u - u_{ms})_t, u - \hat{\alpha}) + a(u - u_{ms}, u - \hat{\alpha}).
\]

By Cauchy-Schwarz inequality and Young’s inequality, we have 
\[
\frac{1}{2} \frac{d}{dt} \| u - u_{ms} \|^2 + \| u - u_{ms} \|^2_a \leq \| u_t - (u_{ms})_t \| \| u - \hat{\alpha} \| + \| u - u_{ms} \| \| u - \hat{\alpha} \|
\]
\[
\leq (\| u_t \| + \| (u_{ms})_t \|) \| u - \hat{\alpha} \| + \frac{1}{2} \| u - u_{ms} \|_a^2 + \frac{1}{2} \| u - \hat{\alpha} \|_a^2.
\]

So, we have 
\[
\frac{d}{dt} \| u - u_{ms} \|^2 + \| u - u_{ms} \|^2_a \leq 2(\| u_t \| + \| (u_{ms})_t \|) \| u - \hat{\alpha} \| + \| u - \hat{\alpha} \|_a^2.
\]

Integrating with respect to time, we have 
\[
\| (u - u_{ms})(\cdot, T) \|^2 - \| (u - u_{ms})(\cdot, 0) \|^2 + \int_0^T \| u - u_{ms} \|^2_a \leq 2(\| u_t \| + \| (u_{ms})_t \|) \| u - \hat{\alpha} \| + \int_0^T \| u - \hat{\alpha} \|^2_a.
\]

By (4.3), we can bound \( u_t \) by the initial data and source function \( f \), that is 
\[
\int_0^T \| u_t \|^2 \leq C \left( \| u_0 \|_a^2 + \int_0^T \| f \|^2 \right).
\]

Similarly, by (4.3), we have 
\[
\int_0^T \| (u_{ms})_t \|^2 \leq C \left( \| u_{0,ms} \|_a^2 + \int_0^T \| f \|^2 \right).
\]

Thus, (4.3), (4.5) and the above two inequalities give 
\[
\| (u - u_{ms})(\cdot, T) \|^2 + \int_0^T \| u - u_{ms} \|^2_a
\]
\[
\leq CH^2 \Lambda^{-1} \kappa_0^{-\frac{1}{2}} \| \kappa^{-\frac{1}{2}} (f - u_t) \|_{L^2(0,T;L^2(\Omega))} \left( \| u_0 \|_a^2 + \| u_{0,ms} \|_a^2 + \int_0^T \| f \|^2 \right)^{\frac{1}{2}}
\]
\[
+ CH^2 \Lambda^{-1} \| \kappa^{-\frac{1}{2}} (f - u_t) \|^2_{L^2(0,T;L^2(\Omega))}.
\]

This completes the proof. □

The following theorem gives the \( L^2 \) error estimate.

**THEOREM 4.5.** If \( f_1 \in L^1(0,T;L^2(\Omega)) \) and \( u_{tt} \in L^1(0,T;L^2(\Omega)) \), then 
\[
\| (u - u_{ms})(T) \| \leq CH^2 \Lambda^{-1} \kappa_0^{-\frac{1}{2}} \left( \max_{0 \leq t \leq T} \| \kappa^{-\frac{1}{2}} (f - u_t) \| + \| \kappa^{-\frac{1}{2}} (f_1 - u_{tt}) \|_{L^1(0,T;L^2(\Omega))} \right)
\]
\[
+ \| u_0 - u_{0,ms} \|, \tag{4.8}
\]
where $C$ is a constant independent of $\kappa$ and the mesh size $H$.

Proof. We rewrite

$$u - u_{ms} = (u - \hat{u}) + (\hat{u} - u_{ms}) := \theta + \rho, \quad \forall t > 0,$$

where $\hat{u}$ is the elliptic projection in the space $V_{ms}$ of the exact solution $u$ and satisfies (4.5) and (4.6). By (4.6), we have

$$\|\theta\| \leq CH^{2} \Lambda^{-1} \kappa_{0}^{-1/2} \|\kappa^{-1/2}(f - u_{t})\|, \quad \forall t > 0. \quad (4.9)$$

By equation (2.3) and (4.4), for all $v \in V_{ms}$ and any $t > 0$, we have

$$((\hat{u} - u_{ms})_{t}, v) + a(\hat{u} - u_{ms}, v) = (\hat{u}_{t}, v) + a(u, v) - (f, v) = ((\hat{u} - u)_{t}, v). \quad (4.10)$$

Taking $v = \rho = \hat{u} - u_{ms} \in V_{ms}$, it follows that

$$((\rho_{t}, \rho) + a(\rho, \rho) = ((\hat{u} - u)_{t}, \rho).$$

Since $a(\rho, \rho) \geq 0$, Cauchy-Schwarz inequality implies

$$\frac{1}{2} \frac{d}{dt} \|\rho\|^2 = \|\rho\| \frac{d}{dt}\|\rho\| \leq \|((\hat{u} - u)_{t})\| \|\rho\|.$$

So,

$$\frac{d}{dt}\|\rho\| \leq \|((\hat{u} - u)_{t})\|.$$

Integrating in time from 0 to $T$, we have

$$\|\rho(\cdot, T)\| \leq \|\rho(\cdot, 0)\| + \int_{0}^{T} \|((\hat{u} - u)_{t})\|.$$

By (4.6), we have

$$\|((\hat{u} - u)_{t})\| \leq CH^{2} \Lambda^{-1} \kappa_{0}^{-1/2} \|\kappa^{-1/2}(f_{t} - u_{tt})\|, \quad \forall t > 0. \quad (4.11)$$

The above inequality implies that

$$\|(\hat{u} - u_{ms})_{T}\| \leq \|(\hat{u} - u_{ms})_{T, 0}\| + \int_{0}^{T} \|((\hat{u} - u)_{t})\|$$

$$\leq \|u_{0} - u_{0, ms}\| + \|\hat{u}_{0} - u_{0}\| + CH^{2} \Lambda^{-1} \kappa_{0}^{-1/2} \int_{0}^{T} \|\kappa^{-1/2}(f_{t} - u_{tt})\|. \quad (4.12)$$

Finally, we have

$$\|(u - u_{ms})(\cdot, T)\| \leq \|(u - \hat{u})(\cdot, T)\| + \|(\hat{u} - u_{ms})(\cdot, T)\|$$

$$\leq CH^{2} \Lambda^{-1} \kappa_{0}^{-1/2} \left( \max_{0 \leq t \leq T} \|\kappa^{-1/2}(f - u_{t})\| + \int_{0}^{T} \|\kappa^{-1/2}(f_{t} - u_{tt})\| ds \right)$$

$$+ \|u_{0} - u_{0, ms}\|. \quad (4.13)$$
where we have used (4.10) and (4.12). This completes the proof.

Now, we ready to consider the error estimates in the $L^2$ norm and energy norm using the relaxed CEM-GMsFEM. The following lemma is necessary to derive the error estimates.

**Lemma 4.6.** [2] Let $u$ be the solution of the elliptic equation (4.7) and $\omega \in V_{rms}$ be the residual projection of $u$. If $\{\chi_j\}$ are the bilinear partition of unity functions and $m = O(\log(\frac{1}{H}))$, where $m$ is the number of oversampling layers in the construction of basis in (3.2), then we have

$$
\|u - \omega\|_a \leq C H^{2}\Lambda^{-\frac{1}{2}} \|\kappa^{-\frac{1}{2}} f\|.
$$

(4.14)

By using Lemma 4.6 and the similar arguments in the proof of Theorem 4.4 and Theorem 4.7, we can derive the estimates for the relaxed CEM-GMsFEM for the parabolic equation.

**Theorem 4.7.** Let $u_{rms} \in V_{rms}$ be the approximate solution of the solution $u$ defined in (2.3) in the space $V_{rms}$. Then

$$
\|(u - u_{rms})(\cdot,T)\|^2 + \int_0^T \|u - u_{rms}\|^2_a
$$

$$
\leq C H^{2}\Lambda^{-\frac{1}{2}} \|\kappa^{-\frac{1}{2}} (f - u_t)\|_{L^2(0,T;L^2(\Omega))} \left(\|u_0\|^2_a + \|u_{0, rms}\|^2_a + \|f\|^2_{L^2(0,T;L^2(\Omega))}\right)^{\frac{1}{2}} + C H^{2}\Lambda^{-\frac{1}{2}} \|\kappa^{-\frac{1}{2}} (f - u_t)\|_{L^2(0,T;L^2(\Omega))},
$$

where $C$ is a constant independent of $\kappa$ and the mesh size $H$.

**Theorem 4.8.** Let $u_{rms} \in V_{rms}$ be the approximate solution of the solution $u$ defined in (2.3). Then

$$
\|u - u_{rms}\| \leq C H^{2}\Lambda^{-\frac{1}{2}} \left(\max_{0 \leq t \leq T} \|\kappa^{-\frac{1}{2}} (f - u_t)\| + \|\kappa^{-\frac{1}{2}} (f - u_t)\|_{L^1(0,T;L^2(\Omega))}\right)
$$

$$
+ \|u_0 - u_{0, rms}\|.
$$

where $C$ is a constant independent of $\kappa$ and $H$.

**4.2. A posteriori error bound.** In addition to a priori error estimates, a posteriori error estimation is also very important. It can give a computable error bound to access the quality of the numerical solution. It also serves as a foundation for an adaptive basis enrichment strategy. Now we derive a posteriori error bound of CEM-GMsFEM for the parabolic equation.

**Theorem 4.9.** Let $u$ be the solution of the parabolic equation (2.3) and $u_{ms}$ the approximate solution of $u$ in the space $V_{ms}$. Then

$$
\|(u - u_{ms})|_a\|^2 + \int_0^T \|u - u_{ms}\|^2_a \leq 2 M(1 + \Lambda^{-1}) \sum_n^N \sum_{i=1}^{N_n} \|R^n_i\|^2_{Q^*} + \|(u - u_{ms})(0)\|^2,
$$

(4.15)

where the local residual $R^n_i$ is defined as

$$
R^n_i(v) = \sum_{t_n}^{t_{n+1}} \left\{(f,v) - ((u_{ms})_t,v) - a(u_{ms},v)\right\}, \quad v \in L^2(t_n, t_{n+1}; V_0(\omega_i)),
$$

and the residual norm is defined by

$$
\|R^n_i\|_{Q^*} := \sup_{v \in L^2(t_n, t_{n+1}; V_0(\omega_i))} \frac{R^n_i(v)}{\|v\|_{L^2(t_n, t_{n+1}; V_0(\omega_i))}}.
$$
The constant \( M \) is the maximum number of overlapping coarse neighborhoods.

**Proof.** First of all, we have

\[
\frac{1}{2} \frac{d}{dt} \| u - u_{ms} \|^2 + \| u - u_{ms} \|^2_a = ((u - u_{ms})_t, u - u_{ms}) + a(u - u_{ms}, u - u_{ms}) \\
= (f, u - u_{ms}) - ((u_{ms})_t, u - u_{ms}) - a(u_{ms}, u - u_{ms}) \\
= (f, z) - ((u_{ms})_t, z) - a(u_{ms}, z),
\]

where \( z = u - u_{ms} \). Let \( \hat{z} \) be the spectral projection of \( z \). Using (2.3), we have

\[
\frac{1}{2} \frac{d}{dt} \| u - u_{ms} \|^2 + \| u - u_{ms} \|^2_a = (f, z - \hat{z}) - ((u_{ms})_t, z - \hat{z}) - a(u_{ms}, z - \hat{z}).
\]

(4.16)

Integrating with respect to time from \( t_n \) to \( t_{n+1} \), we have

\[
\frac{1}{2} \| (u - u_{ms})(\cdot, t_{n+1}) \|^2 + \int_{t_n}^{t_{n+1}} \| u - u_{ms} \|^2_a \\
= R^n(z - \hat{z}) + \frac{1}{2} \| (u - u_{ms})(\cdot, t_n) \|^2,
\]

where we define the global residual \( R^n \) by

\[
R^n(v) = \int_{t_n}^{t_{n+1}} \{ (f, v) - ((u_{ms})_t, v) - a(u_{ms}, v) \},
\]

which is a linear functional on \( Q^n := L^2((t_n, t_{n+1}); V_0) \). We can rewrite

\[
R^n(v) = R^n(\sum_{i=1}^{N_e} \chi_i v) = \sum_{i=1}^{N_e} \int_{t_n}^{t_{n+1}} \{ (f, \chi_i v) - ((u_{ms})_t, \chi_i v) - a(u_{ms}, \chi_i v) \}.
\]

Using the definition of \( R^n \), we have

\[
R^n(v) = \sum_{i=1}^{N_e} R^n_i(\chi_i v).
\]

Notice that

\[
R^n_i(\chi_i(z - \hat{z})) \leq \| R^n_i \|_{Q^i} \| \chi_i(z - \hat{z}) \|_{Q^i},
\]

where \( \| \cdot \|_{Q^i} \) denotes the norm in \( Q^i \). In addition, we have

\[
\| \chi_i(z - \hat{z}) \|^2_{Q^i} = \int_{t_n}^{t_{n+1}} \| \chi_i(z - \hat{z}) \|^2_{a_i} \leq 2 \int_{t_n}^{t_{n+1}} \| z - \hat{z} \|^2_{a_i} + \| z - \hat{z} \|^2_{s_i} \leq 2(1+\Lambda^{-1}) \int_{t_n}^{t_{n+1}} \| \hat{z} \|^2_{a_i},
\]

where \( \| \cdot \|_{a_i} \) and \( \| \cdot \|_{s_i} \) denote the a-norm and s-norm restricted in \( \omega_i \). Therefore,

\[
\frac{1}{2} \| (u - u_{ms})(\cdot, t_{n+1}) \|^2 + \int_{t_n}^{t_{n+1}} \| u - u_{ms} \|^2_a \\
\leq (2(1 + \Lambda^{-1}))^{\frac{1}{2}} \sum_{i=1}^{N_e} \| R^n_i \|_{Q^i} \| u - u_{ms} \|_{Q_i} + \frac{1}{2} \| (u - u_{ms})(\cdot, t_n) \|^2,
\]

where \( \| u - u_{ms} \|^2_{Q_i} = \int_{t_n}^{t_{n+1}} \| u - u_{ms} \|^2_{a_i} \). Using Cauchy Schwarz inequality, we have

\[
\frac{1}{2} \| (u - u_{ms})(\cdot, t_{n+1}) \|^2 + \frac{1}{2} \int_{t_n}^{t_{n+1}} \| u - u_{ms} \|^2_a \\
\leq M(1 + \Lambda^{-1}) \sum_{i=1}^{N_e} \| R^n_i \|^2_{Q^i} + \frac{1}{2} \| (u - u_{ms})(\cdot, t_n) \|^2.
\]

The proof is completed by summing the above over all \( n \). \( \square \)
5. **Full discrete schemes.** In addition to spatial variable discretization, we also need to discretize the temporal variable to solve the parabolic equation. In the section, we present two widely used schemes: backward Euler and forward Euler. For the presentation, we use the following notations, for any \( n = 0, 1, 2, \cdots \),

\[
t^n := n \Delta t, \quad u^n := u(t^n, x).
\]

5.1. **Backward Euler.** We first consider the backward Euler method. Let \( \Delta t \) be the time step and \( V_{ms} \) be the multiscale finite element space. And let \( U^n_{ms} := u_{ms}(t_n) \).

Then the fully discrete formulation using backward Euler method is

\[
\begin{aligned}
\left\{ \begin{array}{l}
(U^n_{ms} - U^{n-1}_{ms})/\Delta t, v) + a(U^n_{ms}, v) = (f(t_n), v) \quad \forall v \in V_{ms} \\
U^0_{ms} = u_{0, ms}.
\end{array} \right.
\]

(5.1)

We can show that the backward Euler method is unconditionally stable. In the equations (5.1), we choose \( v = U^n_{ms} \).

Because \( a(U^n_{ms}, U^n_{ms}) \geq 0, \)

\[
\|U^n_{ms}\|^2 - (U^{n-1}_{ms}, U^n_{ms}) \leq \Delta t \|f^n\| \cdot \|U^n_{ms}\|,
\]

(5.2)

where \( f^n = f(t_n) \). By Cauchy-Schwarz inequality,

\[
(U^n_{ms}, U^n_{ms}) \leq \|U^n_{ms}\| \cdot \|U^n_{ms}\|,
\]

the inequality (5.2) implies

\[
\|U^n_{ms}\| \leq \|U^{n-1}_{ms}\| + \Delta t \|f^n\|.
\]

By repeating the above inequality, we have

\[
\|U^n_{ms}\| \leq \|U^0_{ms}\| + \Delta t \sum_{j=1}^{n} \|f^j\|.
\]

(5.3)

This shows that the backward Euler method is unconditionally stable.

The following theorem gives the convergence result for the fully discrete scheme using backward Euler.

**Theorem 5.1.** Let \( U^n_{ms} \) and \( u \) be the solution of (5.1) and (2.1), respectively. Then

\[
\|U^n_{ms} - u(t_n)\| \leq CH^2 \Lambda^{-1} \kappa_0^{-\frac{1}{2}} \|\kappa^{-\frac{1}{2}}(f^n - u_t(t_n))\| + \Delta t \int_0^{t_n} \|u_{tt}\| ds + \|u_{0, ms} - u_0\|.
\]

**Proof.** Let \( \hat{u} \) be the elliptic projection of \( u \). Then

\[
U^n_{ms} - u(t_n) = (U^n_{ms} - \hat{u}(t_n)) + (\hat{u}(t_n) - u(t_n)) = \theta^n + \rho^n
\]

From the inequality (4.5), we have

\[
\|ho^n\| = \|\hat{u}(t_n) - u(t_n)\| \leq CH^2 \Lambda^{-1} \kappa_0^{-1} \|\kappa^{-\frac{1}{2}}(f^n - u_t(t_n))\|.
\]

By equation (2.1) and (4.3), for any \( v \in V_{ms} \),

\[
((\hat{u} - u_{ms})_t, v) + a(\hat{u} - u_{ms}, v) = (\hat{u}_t, v) + a(u, v) - (f, v)
= ((\hat{u} - u)_t, v).
\]

(5.4)
Because \( \partial_t U_{ms}^n = \frac{U_{ms}^n - U_{ms}^{n-1}}{\Delta t} \), we can rewrite (5.4) as
\[
(\partial_t \theta^n, v) + a(\theta^n, v) = (u(t_n) - \partial_t \tilde{u}^n, v).
\] (5.5)

Due to
\[
u(t_n) - \partial_t \tilde{u}^n = (u(t_n) - \partial_t u^n) + (\partial_t u^n - \partial_t \tilde{u}^n)
:= u_1^n + w_2^n,
\] (5.6)

combining (5.3), (5.5) and (5.6) gives
\[
\|\theta^n\| \leq \|\theta^0\| + \Delta t \sum_{j=1}^n |w_1^n| + \Delta t \sum_{j=1}^n |w_2^n|.
\] (5.7)

If we choose \( U_{ms}^0 = u_{0,ms} \) and apply (4.6), we have
\[
\|U_{ms}^0 - \tilde{u}_0\| \leq \|u_{0,ms} - u_0\| + \|u_0 - \tilde{u}_0\|.
\]

By Taylor’s formula, it follows that
\[
w_1^n = u(t_j) - (\Delta t)^{-1}(u(t_j) - u(t_{j-1})) = (\Delta t)^{-1} \int_{t_{j-1}}^{t_j} (s - t_{j-1}) u_{tt}(s) ds.
\]

Then
\[
\Delta t \sum_{j=1}^n |w_1^n| \leq \sum_{j=1}^n \left\| \int_{t_{j-1}}^{t_j} (s - t_{j-1}) u_{tt}(s) ds \right\| \leq \Delta t \int_0^{t_n} \|u_{tt}\| ds.
\]

Because
\[
w_2^n = \partial_t u^j - \partial_t \tilde{u}^j = (\Delta t)^{-1} \int_{t_{j-1}}^{t_j} (u - \tilde{u}) ds,
\]

we have
\[
\Delta t \sum_{j=1}^n |w_2^n| \leq \sum_{j=1}^n \left\| u(t_j) - \tilde{u}(t_j) \right\|.
\] (5.8)

Hence,
\[
\|U_{ms}^n - u(t_n)\| \leq C H^2 \Lambda^{-1} \kappa_0^{-\frac{1}{2}} \|f^n - u(t_n)\| + \Delta t \int_0^{t_n} \|u_{tt}\| ds + \|u_{0,ms} - u_0\|.
\]

5.2. Forward Euler discretization. Using the forward Euler method, we have the following weak formulation for (2.1)
\[
\begin{cases}
\left( \frac{U_{ms}^{n+1} - U_{ms}^n}{\Delta t}, v \right) + a(U_{ms}^n, v) = (f(t_n), v) & \forall v \in V_{ms}, n \geq 1 \\
U_{ms}^0 = u_{0,ms}.
\end{cases}
\] (5.9)
If we define
\[ V_{ms} = \text{span}\{\varphi_{k,ms} | 1 \leq k \leq \sum_{i=1}^{N} L_i \} = \text{span}\{\psi^{(i)}_{j,ms} | 1 \leq j \leq L_i, 1 \leq i \leq N \}, \]
then \( U_{ms}^n \) and \( f(t_n) \) can be expressed as follows,
\[ U_{ms}^n = \sum_k \alpha^n_k \varphi_{k,ms}, \quad f(t_n) = \sum_k b^n_k \varphi_{k,ms}. \]

We can express the equation (5.9) in the following matrix form,
\[ M \alpha^{n+1} = (M - \Delta t A) \alpha^n + \Delta t b^n, \quad (5.10) \]
where
\[ (\alpha^n)_i = \alpha^n_i, \quad (b^n)_i = b^n_i, \]
\[ (M)_{i,j} = \int_{\Omega} \varphi_{i,ms} \varphi_{j,ms}, \quad (A)_{i,j} = \int_{\Omega} \kappa \nabla \varphi_{i,ms} \cdot \nabla \varphi_{j,ms}. \]
Using the equation (5.10) and recursion, we obtain
\[ \alpha^n = (I - \Delta t M^{-1} A)^n \alpha^0 + \sum_{i=0}^{n-1} (I - \Delta t M^{-1} A)^i \Delta t M^{-1} b^{n-i} \quad (5.11) \]
It is easy to prove that the equation (5.11) is stable if and only if \( |1 - \Delta t \lambda| \leq 1 \), where \( \lambda \) is the eigenvalue of
\[ a(\varphi_{i,ms}, v) = \lambda (\varphi_{i,ms}, v), \quad \forall v \in V_{ms}. \]
We remark that the analysis for the convergence is similar to that for the backward Euler scheme, so we omit it.

6. Numerical results. In this section, we present some numerical results by using CEM-GMsFEM to solve the parabolic equation with the multiscale permeability field \( \kappa(x) \). For time discretization, we will use the backward Euler scheme. In Section 6.1 we use CEM-GMsFEM to solve the parabolic equation with different multiscale permeability fields. In Section 6.2 the numerical results using the CEM-GMsFEM will be given for the parabolic equation in fracture porous media. In Section 6.3 we verify the posteriori error bound by numerical examples.

For the numerical examples, we consider the parabolic equation (2.1) with the homogeneous Dirichlet boundary condition, source term \( f(x,t) \) and initial condition \( u_0(x) \) are defined by
\[ f(x,t) = 3\pi^2 \exp(\pi^2 t) \sin(\pi x_1) \sin(\pi x_2), \quad x \in [0,1]^2, \]
\[ u_0(x) = \sin(\pi x_1) \sin(\pi x_2), \quad x \in [0,1]^2. \]
Here \( x := (x_1, x_2) \). In the spatial direction, the computational domain is \( \Omega = [0,1]^2 \) and we use 200 \times 200 fine grid to compute a reference solution. We will choose different coarse grid size to compute the relative error between the fine-scale solution and CEM-GMsFEM solution. Two high contrast permeability fields \( \kappa(x) \) used in the numerical examples are shown in Figure 6.1.
To measure the approximation accuracy, the relative errors between reference solution and multiscale method are utilized and defined as follows,

$$
\varepsilon = \frac{\|u_h(x,T) - u_{ms}(x,T)\|_{L^2(\Omega)}}{\|u_h(x,T)\|_{L^2(\Omega)}},
$$

$$
\varepsilon_a = \frac{\|u_h(x,T) - u_{ms}(x,T)\|_{a(\Omega)}}{\|u_h(x,T)\|_{a(\Omega)}},
$$

where \(u_h\) is the fine-scale FEM solution in fine grid and \(u_{ms}\) is CEM-GMsFEM solution.

6.1. Numerical results for CEM-GMsFEM. In this subsection, we present the numerical results using CEM-GMsFEM to solve the equation (2.1) with different permeability fields. In Example 1, the permeability field \(\kappa_1\) depicted in Figure 6.1 (left) will be used. The contrast ratio is \(10^4\) in the permeability field \(\kappa_1\). In the \(V_{ms}\) space, the number of oversampling layers used is \(4 \ast \log(H)/\log(1/10)\). In Figure 6.2, we present the results for the first example using different numbers of local basis functions when fixing the coarse grid size \(H = 1/10\). From the figure, we obtain two observations: (1) the error decreases as the number of local basis functions increases; (2) when the number of local basis functions exceeds a certain number, the error decreases very slowly as the eigenvalues of the local spectral problems decay slowly. So we can get a good accuracy by using only a few local basis functions on each coarse block. In this example, four local basis functions for each coarse block can achieve very good accuracy. Figure 6.3 shows the relative error \(\varepsilon_a\) with different numbers of oversampling layers when we fix the coarse grid size \(H = 1/10\) and use four basis functions on each coarse block. By the figure, we can see that as the number of oversampling layer increases, the approximation becomes more accurate and the error decreases very slowly once the number of oversampling layers attains a certain number. To show the relationship between the error and the coarse grid size \(H\), Table 6.1 lists the numerical results (\(T = 1, \Delta t = 0.01\)) with different coarse grid sizes \(H\). It shows that: (1) as the the coarse grid becomes finer, the error decreases; (2) the CEM-GMsFEM for the parabolic equation has a convergence rate proportional to the
Fig. 6.2. Numerical result with different numbers of local basis functions (Example 1)

Fig. 6.3. Numerical result with different numbers of oversampling layers (Example 1)

course grid size $H$. Based on the above theoretical analysis, the error depends on $H$ and $\Lambda$. Different sizes of the coarse grid may result in different $\Lambda$. Given a fixed $\Lambda$, the $L^2$ norm error can achieve a second order convergence rate and the energy norm error has a first order convergence rate. Figure 6.4 shows the fine-scale FEM solution and the CEM-GMsFEM solution at times $T = 1$, which show almost the same solution profile.

Table 6.1

| Basis # per element | $H$   | $m$ | $\varepsilon$ | $\varepsilon_a$ |
|---------------------|-------|-----|--------------|-----------------|
| 4                   | 1/10  | 4   | $4.5137E-04$ | $9.7892E-03$   |
| 4                   | 1/20  | 6   | $1.1483E-04$ | $3.7640E-03$   |
| 4                   | 1/40  | 7   | $1.7609E-05$ | $1.5141E-03$   |

In the second example, we use the same equation but with a different permeability field $\kappa_2$ shown in Figure 6.5 (right) and the contrast is still $10^4$. The fine grid size, the coarse grid size and the oversampling layer are the same as the previous example. In
Fig. 6.4. The left is the reference solution, the right is the CEM-GMsFEM solution. $H = \frac{1}{10}$, 4 oversampling layers and 4 local multiscale basis functions, $T = 1$

Figure 6.5, we present the results for using different number of local basis functions when we fix the coarse grid size $H = 1/10$. When increasing the number of basis functions on each coarse grid, the error will decrease. As the same as Example 1, four basis functions for each coarse block can give a very good approximation. In Figure 6.6, the relative error $\varepsilon_a$ with different numbers of oversampling layers is given. Table 6.2 shows the numerical results with different coarse grid sizes $H$.

| Basis # per element | $H$     | $m$ | $\varepsilon$         | $\varepsilon_a$ |
|---------------------|---------|-----|------------------------|-----------------|
| 4                   | 1/10    | 4   | $1.5300E-03$           | $3.9793E-02$    |
| 4                   | 1/20    | 6   | $2.5246E-04$           | $7.2485E-03$    |
| 4                   | 1/40    | 7   | $3.3741E-05$           | $2.7634E-03$    |

6.2. Application to a fractured medium. In this subsection, we consider a single phase flow in a fracture porous medium. The permeability value in fracture is much larger than that in the surrounding medium. We use the discrete fracture model (DFM) introduced in [10] and apply CEM-GMsFEM to the fracture model. The main idea is to treat the fracture as interface between subdomains. Thus, the spatial domain is divided into matrix and fractures, where the matrix is two dimensional and
the fractures are one dimensional, i.e.,
\[ \Omega = \Omega_m \cup (\bigcup_i \Omega_{\text{frac},i}) \],
where the subscript \(m\) represents the matrix regions and frac represents the fracture regions. So we can rewrite the weak formulation corresponding to (2.1) as
\[
\int_\Omega u_t \cdot v + \int_\Omega \kappa \nabla u \cdot \nabla v \\
= \int_{\Omega_m} u_t \cdot v + \sum_i \int_{\Omega_{\text{frac},i}} u_t \cdot v + \int_{\Omega_m} \kappa \nabla u \cdot \nabla v + \sum_i \int_{\Omega_{\text{frac},i}} \kappa \nabla u \cdot \nabla v \\
= \int_\Omega f v. \tag{6.1}
\]
Using CEM-GMsFEM, we take into account the fracture distributions in constructing the auxiliary space and solving the local minimizing problems. We show the computation domain and fracture in Figure 6.7. In the fracture domain, the permeability is \(10^4\). In the matrix domain, the permeability is 1. In the discrete fracture model, we use the constraint energy minimizing in the \(V_{ms}\) space. We show the numerical solution in \((T = 1, \Delta t = 0.01)\) in Figure 6.8. In this figure, the domain has three fractures and the reference solution is computed by the FEM on 160 \(\times\) 160 fine grid. We use four local multiscale basis functions on each coarse block and the number of oversampling layers is 4 to compute the solution of CEM-GMsFEM. The figure demonstrates that the CEM-GMsFEM gives a good approximation solution for the case of the fracture porous medium. Table 6.3 gives the numerical results \((T = 1, \Delta t = 0.01)\) with different coarse grid sizes \(H\). By this table, we observe that the error significantly decreases as the size of the coarse grid gets finer.

6.3. A posteriori error bound. In this section, we present the numerical results to confirm the posteriori error bound in Theorem 4.9. For simplicity of presentation, we define the notations as follows
\[
\varepsilon_L := \|u - u_{ms}(T)\|^2 + \int_0^T \|u - u_{ms}\|^2_t, \quad \varepsilon_R := \sum_n \sum_i \|R_n^i\|_Q^2 + \|(u - u_{ms})(0)\|^2,
\]
where \( u \) is the reference solution and \( u_{ms} \) is the CEM-GMsFEM solution. In order to compute \( \| R^n_i \|_{Q^*} \), we solve the problem: find \( \phi^n_i \in V_0(\Omega_i) \) such that

\[
a(\phi^n_i, v) = (f, v) - (\frac{u^{n+1}_{ms} - u^n_{ms}}{\Delta t}, v) - a(u^{n+1}_{ms}, v), \quad \forall v \in V_0(\Omega_i).
\]

Thus,

\[
\| R^n_i \|_{Q^*} = (\Delta t)^{\frac{1}{2}} \| \phi^n_i \|_a.
\]

We consider the parabolic equation (2.1) with the homogeneous Dirichlet boundary condition and zero initial condition, the source term

\[f(x, t) = t^2 + (x_1 + x_2)^2, \quad x \in [0, 1]^2.\]

In the example, we take the permeability field \( \kappa_2 \) depicted in Figure 6.1 (right). We use 200 \( \times \) 200 fine grid in the spatial domain and the time step \( \Delta t = 0.01 \). Due to the eigenvalue problem has three small eigenvalues in each coarse cell, we will use three multiscale basis functions in each coarse cell. Table 6.4 shows the numerical result with different coarse grid sizes. By the table, we observe that \( \sum_n \sum_i \| R^n_i \|_{Q^*}^2 + \| (u - u_{ms})(0) \|^2 \) is a suitable a posteriori error estimate and the ratio \( \frac{\varepsilon}{\varepsilon_R} \) keeps stable as coarse grid size varies. To see how the local permeability structure affects on the
local residual of CEM-GMsFEM, we arrange the local residuals \( \{ \Sigma_n \| R_n^i \|_Q^2 \}_{i=1}^{N_c} \) in ascending order, where \( N_c \) is the number of coarse vertices. When \( N_c = 121 \), we plot the permeability profile in some regions \( \omega_i \) and compute \( \Sigma_n \| R_n^i \|_Q^2 \) in these local regions in Figure 6.9. For \( N_c = 441 \), we plot the local permeability profiles in some region \( \omega_i \) in Figure 6.10 and compute the value of \( \Sigma_n \| R_n^i \|_Q^2 \) in these regions. In Figure 6.9 we observe that the local permeability map \( \kappa(\omega_{25}) \) in the middle plot is more complex than the right map \( \kappa(\omega_{39}) \), but the local residual \( \Sigma_n \| R_n^{25} \|_Q^2 \) is much smaller than \( \Sigma_n \| R_n^{39} \|_Q^2 \). In Figure 6.10 the middle plot \( \kappa(\omega_{21}) \) is much more simple than the left plot \( \kappa(\omega_{68}) \), but the local residual \( \Sigma_n \| R_n^{21} \|_Q^2 \) is larger than \( \Sigma_n \| R_n^{68} \|_Q^2 \). These results imply that the value of the local residual may not depend on the local pattern of the medium, but depends on the nonlocal structure of the medium.

### Table 6.3

| Basis # per element | \( H \) | \( m \) | \( \varepsilon \) | \( \varepsilon_n \) |
|---------------------|--------|--------|----------------|----------------|
| 4                   | 1/4    | 3      | 2.5751E−02    | 1.4806E−02    |
| 4                   | 1/8    | 4      | 7.1869E−03    | 5.6841E−03    |
| 4                   | 1/16   | 5      | 2.0709E−03    | 2.1280E−03    |

### Table 6.4

| \( H \) | oversampling layers | \( \varepsilon_L \) | \( \varepsilon_R \) | \( \varepsilon_{\text{avg}} \) |
|---------|---------------------|---------------------|---------------------|---------------------|
| 1/10    | 4                   | 8.4905E−05          | 3.1505E−04          | 3.7107              |
| 1/20    | 6                   | 3.5436E−06          | 1.1161E−05          | 3.1496              |
| 1/40    | 7                   | 3.8295E−07          | 1.1989E−06          | 3.1306              |

### Fig. 6.9

Some local permeability fields \( (N_c = 121, H = 1/10) \).

7. Conclusion. In this paper, we have presented CEM-GMsFEM for solving the parabolic problems in multiscale porous media. The analysis showed that the convergence depends on the coarse mesh size and the decay of eigenvalues of local spectral problems. For CEM-GMsFEM, the first step is to construct the auxiliary space through solving local spectral problems. The second step is to solve a constraint energy minimizing problem to construct the multiscale basis functions in the
oversampling local regions. In this paper, we have constructed the elliptic projection in the space spanned by CEM-GMSFEM basis functions for convergence analysis. Then we showed the convergence of the semidiscrete formulation. The method can achieve the second order convergence rate in the $L^2$ norm and first order convergence rate in the energy norm with respect to coarse mesh size. We also derived the convergence and stability of the full discrete formulation. A posteriori error bound was given and the numerical results showed that it is a proper upper bound. Some numerical results have been presented to confirm the theoretical results.
