**INTRODUCTION**

About 50% of the world’s human population is infected by *Helicobacter pylori*, a gastric pathogen causing gastritis in all infected individuals and more severe gastric disease in 10–15% of cases (Amieva and El-Omar, 2008; Atherton and Blaser, 2009; Polk and Peek, 2010). *H. pylori* can infect humans lifelong as the consequence of a highly complex host–pathogen crosstalk, and is an excellent model system to study bacterially induced epithelial cell signaling cascades which are of relevance to neoplasia. *H. pylori* virulence factors mediate a range of host cell responses and contribute to pathogenesis. The *cag* pathogenicity island (PAI) encodes components of a type IV secretion system (T4SS), and the virB1–11 gene cluster including the so-called coupling protein VirD4, which transports CagA into host cells. *H. pylori* infection causes aberrant signaling pathways in the early interaction of CagL with integrins. While CagL binding to host cells is mediated primarily by the RGD motif, we identified an auxiliary binding motif for CagL–integrin interaction. Here, we report on a surface exposed FEANE (Phe-Glu-Ala-Asn-Glu) interaction motif in spatial proximity to the RGD sequence, which enhances the interactions of CagL with integrins. It will be referred to as RGD helper sequence (RHS). Competitive cell adhesion assays with recombinant wild type CagL and point mutants, competition experiments with synthetic cyclic and linear peptides, and peptide array experiments revealed amino acids essential for the interaction of the RHS motif with integrins. Infection experiments indicate that the RHS motif plays a role in the early interaction of *H. pylori* T4SS with integrin, to trigger signaling and to inject CagA into host cells. We thus postulate that CagL is a versatile T4SS surface protein equipped with at least two motifs to promote binding to integrins, thereby causing aberrant signaling within host cells and facilitating translocation of CagA into host cells, thus contributing directly to *H. pylori* pathogenesis.

---

*Helicobacter pylori* is a specific gastric pathogen that colonizes the stomach in more than 50% of the world’s human population. Infection with this bacterium can induce several types of gastric pathology, ranging from chronic gastritis to peptic ulcers and even adenocarcinoma. Virulent *H. pylori* isolates encode components of a type IV secretion system (T4SS), which form a pilus for the injection of virulence proteins such as CagA into host target cells. This is accomplished by a specialized adhesin on the pilus surface, the protein CagL, a putative VirB5 ortholog, which binds to host cell β1 integrin, triggering subsequent delivery of CagA across the host cell membrane. Like the human extracellular matrix protein fibronectin, CagL contains an RGD (Arg-Gly-Asp) motif and is able to trigger intracellular signaling pathways by RGD-dependent binding to integrins. While CagL binding to host cells is mediated primarily by the RGD motif, we identified an auxiliary binding motif for CagL–integrin interaction. Here, we report on a surface exposed FEANE (Phe-Glu-Ala-Asn-Glu) interaction motif in spatial proximity to the RGD sequence, which enhances the interactions of CagL with integrins. It will be referred to as RGD helper sequence (RHS). Competitive cell adhesion assays with recombinant wild type CagL and point mutants, competition experiments with synthetic cyclic and linear peptides, and peptide array experiments revealed amino acids essential for the interaction of the RHS motif with integrins. Infection experiments indicate that the RHS motif plays a role in the early interaction of *H. pylori* T4SS with integrin, to trigger signaling and to inject CagA into host cells. We thus postulate that CagL is a versatile T4SS surface protein equipped with at least two motifs to promote binding to integrins, thereby causing aberrant signaling within host cells and facilitating translocation of CagA into host cells, thus contributing directly to *H. pylori* pathogenesis.
receptor for the T4SS was integrin $\alpha_5\beta_1$, according to a series of experiments including respective knockout cell lines, gene silencing RNAs, function-blocking antibodies, and competition studies (Kwok et al., 2007). The bacterial interaction partner was identified as CagL, a VirB5 ortholog, and specialized adhesin that is targeted to the pilus surface, where it binds to integrin $\alpha_5\beta_1$ and mediates receptor-dependent delivery of CagA into gastric epithelial cells (Backert et al., 2008, 2011). Like fibronectin, an extracellular matrix protein and natural ligand of integrin $\alpha_5\beta_1$, CagL contains an arginine–glycine–aspartate (RGD) motif that was shown to be important for interaction with integrin $\alpha_5\beta_1$ on host cells (Kwok et al., 2007). Binding of CagL during infection or by incubation with recombinant protein in vitro elicits downstream signaling like tyrosine kinase activation of several proteins including EGF-receptor, FAK, and Src (Kwok et al., 2007; Saha et al., 2010; Tegtmeyer et al., 2010) as well as stimulation of ERK1/2 MAP kinase (Wiedemann et al., 2012). In line with these observations, various other structural T4SS proteins have subsequently also been demonstrated to bind to $\beta_1$ integrins in vitro, including CagA, CagL, and CagY (Jiménez-Soto et al., 2009). In the same study, mutation of the RGD motif in CagL revealed no reduction of injected CagA during infection (Jiménez-Soto et al., 2009). Using mass spectrometry it was further reported that surface exposed CagL associates with two other cagPAI proteins, CagI, and CagH (Shaffer et al., 2011). All three factors are required for CagA translocation into host cells. SEM analysis revealed that these proteins are involved in the formation of T4SS pili. The H. pylori mutant strains $\Delta cagI$ and $\Delta cagL$ failed to form T4SS pili, while the $\Delta cagH$ mutant revealed a hyperpiliated phenotype and produced pili that are elongated and thickened as compared to those of the wild type (WT) bacteria (Shaffer et al., 2011). This suggests that T4SS pili dimensions may be regulated by CagH. Taken together, the above results indicate that CagH, CagL, and CagL are components of a T4SS subassembly complex involved in the biogenesis of pili that interact with integrin $\alpha_5\beta_1$ (Kwok et al., 2007; Shaffer et al., 2011). However, the exact co-operation of the various integrin-targeting cagPAI proteins is not yet clear and needs to be investigated.

We recently reported on cell-based in vitro binding studies with WM-115 and AGS cells revealing that CagL not only interacts with integrin $\alpha_5\beta_1$, but also with $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins (Conradi et al., 2011; Wiedemann et al., 2012). Infection and in vitro binding studies showed that CagL induces gastric expression via a novel integrin $\alpha_v\beta_3$-integrin linked kinase signaling complex independent of CagA infection (Wiedemann et al., 2012). CagL–integrin $\alpha_v\beta_3$ interactions were demonstrated by immunoprecipitation and Biacore binding studies. In addition, the adhesion of WM-115 cells to immobilized CagL was inhibited by cyclic RGD peptides with pre-defined conformation, where the sequence was based on the CagL sequence Ala-Leu-Arg-Gly-Asp-Leu-Ala (ALRGDLA; Conradi et al., 2011). The application of the so-called spatial screening approach had previously been applied in the screening of cyclic RGD peptides and resulted in highly active peptides that efficiently and selectively inhibit the interaction of extracellular matrix proteins like vitronectin, fibronectin, and fibrinogen with the integrins $\alpha_v\beta_3$, $\alpha_v\beta_1$, and $\alpha_v\beta_5$ in the nanomolar IC$_{50}$ range (Gurrath et al., 1992; Pfaff et al., 1994; Haubner et al., 1996, 1997; Weide et al., 2007). The spatial screening approach makes use of incorporation of single $\alpha$-amino acids into cyclic peptides in order to lock the conformation and to predictably present the amino acid side chain functional groups in a well-defined manner. $\alpha$-Amino acids are known to induce and stabilize discrete turn structures in linear and, especially, cyclic peptides. Different cyclic RGD peptides with the CagL basic sequence ALRGDLA and a $\alpha$-amino acid in different positions were synthesized. The variation of the amino acid stereochemistry contributes to different backbone structures, increases the spatial diversity, and provides constrained peptides with different $\beta$- and $\gamma$-turns. The structures were evaluated using NMR and molecular dynamics calculations, and activities of the different peptides were determined in cell adhesion assays. These structure–activity relationship studies revealed a $\beta$-turn around Asp-$\alpha$-Leu-Ala-Arg to be favorable for integrin interactions (Conradi et al., 2011). The corresponding cyclopeptides were shown to inhibit integrin-mediated interactions of WM-115 cells with CagL. In particular, the cyclopeptide-7 [c(-RGDIA)]; Table 3, $\alpha$-amino acids are written in small letters] displayed high activity (Conradi et al., 2011).

In comparison with purified CagLWT, purified CagL mutants (CagLR$\Delta$ and CagLRGA) exhibited decreased, but not completely abolished affinity to integrin $\alpha_5\beta_1$, $\alpha_v\beta_3$, and $\alpha_v\beta_5$ in vitro (Kwok et al., 2007; Conradi et al., 2011; Wiedemann et al., 2012). Other recent studies indicated that the RGD motif of CagL is certainly important but not sufficient for triggering cell signaling (Tegtmeyer et al., 2010; Wiedemann et al., 2012). Taken together, these data strongly underscore the importance of the RGD motif for CagL binding (Conradi et al., 2011), but also suggested the existence of one or more yet unidentified auxiliary motifs that is/are involved in CagL–integrin interactions. Here we report that another CagL motif, a FEANE-containing sequence, in proximity to the RGD motif, participates in binding of CagL to integrins (thus referred to as RHS) and is able to induce cell binding and signaling both in vitro and during H. pylori infection of gastric epithelial cells.

**MATERIALS AND METHODS**

**HUMAN CELL CULTURE AND H. PYLORI STRAINS**

The human epithelial melanoma cell line WM-115 (ATCC, Wesel, Germany; CRL-1675™) is an adherent growing cell line with continuous integrin expression (mainly integrin $\alpha_5\beta_1$, $\alpha_v\beta_3$, and $\alpha_v\beta_5$) and was cultivated in DMEM medium (PAA, Pasching, Austria) supplemented with 10% fetal bovine serum and 50 µg/ml gentamicin (PAA, Pasching, Austria). The human gastric adenocarcinoma cell line AGS (ATCC CRL-1739™) was cultivated in RPMI 1640 medium, which was supplemented with 10% fetal calf serum (Gibco, Paisley, UK). Cells were cultivated at 37°C and 5.3% (v/v) CO$_2$ and subcultivated in a ratio of 1:3–1:5 every 2–3 days at a confluence of 70% to 90%. The H. pylori strains P12 WT and P12$cagL$ were generated and grown as described (Kwok et al., 2007). To complement the P12$cagL$ mutant strain, genes encoding CagL$\Delta$ or CagL mutant proteins were introduced into the chromosomal ureA locus, using a pAD1-derived plasmid. CagL proteins expressed from the ureA promoter contain a hemagglutinin (HA) tag introduced following the signal sequence at amino acid position 22 (Shaffer et al., 2011). For infection, H. pylori were
grown for 2 days in thin layers and added at a multiplicity of infection (MOI) of 50 or 100 (Selbach et al., 2002; Moese et al., 2004). The number of elongated AGS cells in each experiment was quantified in 10 different 0.25 mm² fields (Tegtmeier et al., 2011b). All experiments were done in triplicate.

**CagL PROTEIN EXPRESSION AND PURIFICATION**

CagL<sup>WT</sup> and mutants were expressed as C-terminal His-tag fusions in vector pET28a (Novagen®, Merck, Darmstadt, Germany) and purified as described earlier (Kwok et al., 2007). Briefly, *E. coli* ER2566 (NEB, Ipswich, USA) transformed with the plasmids were grown in 10 ml LB medium at 37°C. After overnight incubation, 500 ml of fresh LB medium were added and shaken for another 2.5–3 h until reaching OD<sub>600</sub> = 1. Then 300 µl of a 1-mM IPTG stock solution was added and the bacteria were grown for 1.5 h to induce CagL expression. Bacterial pellets were collected by centrifugation and then resuspended in ice-cold buffer CW (50 mM KH<sub>2</sub>PO<sub>4</sub>–K<sub>2</sub>HPO<sub>4</sub>, pH 7.5, 200 mM NaCl) supplemented with 5% FBS. The solution was centrifuged and the supernatant was used for CagL purification. The inclusion bodies were solubilized in buffer LW (50 mM KH<sub>2</sub>PO<sub>4</sub>–K<sub>2</sub>HPO<sub>4</sub>, pH 7.5, 200 mM NaCl, 6 M guanidine hydrochloride) and refolded by a rapid dilution approach in ice-cold refolding buffer (50 mM Tris–HCl, pH 8.2, 20 mM NaCl, 0.1 mM KCl, 1 mM EDTA, 2 mM reduced glutathione, 0.2 mM oxidized glutathione) using a dual-channel syringe pump (KD Scientific Inc., Holliston, USA) with a flow of 0.1 ml/min. After refolding, CagL was further purified by metal-chelate affinity chromatography through Talon<sup>®</sup> resin (BD Biosciences). Protein concentrations of the resultant samples were determined by NanoDrop 1000 (Thermo Scientific, Waltman, USA) and typically yielded a total amount of about 1.5 mg CagL in 10 ml buffer. Purification of CagL was judged to be >95% homogeneity by SDS-PAGE/Coomassie Blue staining. The folded conformation of the purified CagL proteins was subsequently confirmed by circular dichroism (CD) as described below.

**SITE-DIRECTED MUTAGENESIS**

Site-directed mutagenesis of CagL was performed using the corresponding pET28a or pBAD vectors as DNA template (Table 1). For amplification, Phusion High-Fidelity DNA Polymerase (NEB, Ipswich, USA) was used, followed by PCR purification (MinElute PCR Purification Kit, Qiagen, Hilden, Germany), digestion with DpnI (Promega, Madison, USA), and ligation using T4 DNA Ligase (Promega). Re-sequencing and Western blotting of *E. coli* or *H. pylori* strains, respectively, verified the appropriate expression of CagL in the resulting plasmids.

**CELL ADHESION ASSAYS WITH WM-115 CELLS**

The cell adhesion assays to immobilized CagL proteins were performed as described previously (Conradi et al., 2011). A 96 well microtiter plate (Nunc MaxiSorp<sup>®</sup>, Thermo Fisher Scientific Inc., Waltham, USA) was coated with 100 µl of protein solution (CagL<sup>WT</sup> or mutant; 10–20 µg/ml) per well, and incubated for 1 h at 37°C. The solution was aspirated and free binding sites were blocked with 100 µl of a solution, consisting of 2% (w/v) fatty acid-free BSA (PAA, Pasching, Austria) in PBS for 1 h at 37°C. The adhesion assays were performed with WM-115 human epithelial cancer cells. This cell line was chosen for the cell adhesion assays due to a constitutive expression of integrin α<sub>5</sub>β<sub>1</sub>, α<sub>6</sub>β<sub>3</sub>, and α<sub>v</sub>β<sub>3</sub>, and was shown to display reproducible adherence to CagL and fibronectin (Conradi et al., 2011). The WM-115 cells were cultivated to a confluence of 70%, and detached with Trypsin-EDTA (0.05/0.02% in D-PBS; PAA, Pasching, Austria). After washing with DMEM medium, the cells were resuspended in DMEM medium with 1 mg/ml fluorescein diacetate (Sigma-Aldrich, St. Louis, USA), adjusted to a cell density of 1 × 10<sup>5</sup> cells/ml and incubated at 37°C for 30 min under steady shaking. Two DMEM washing steps were performed to remove excess fluorescein diacetate. The cells were resuspended in DMEM medium containing divalent cations Ca<sup>2+</sup> and Mg<sup>2+</sup> (2 mM) to a cell density of 1 × 10<sup>5</sup> cells/ml and incubated in the dark on ice for 30 min. Subsequently, the cell solution was distributed into solutions of peptides ranging in concentrations of millimolar to nanomolar, and the resulting mixtures were incubated at 37°C for 30 min. The fluorescence of cells was measured (λ<sub>ex</sub> 485 nm; λ<sub>em</sub> 514 nm) using an Infinite 200 Microplate Reader (Tecan, Männedorf, Switzerland). The inhibition concentration IC<sub>50</sub>, confidence interval CI<sub>95%</sub>, and the square of the correlation coefficient R<sup>2</sup> values were evaluated. To test the accuracy of the fit model for the non-linear regression a “Runs test” was performed and high P-values were obtained for all measurements (data not shown), which support the chosen regression model. All evaluation was performed using the GraphPad Prism 4.03 Software (GraphPad, San Diego, USA).

**HELCOBACTER PYLORI BINDING TO AGS CELLS**

Infection of AGS at a density of 3.2 × 10<sup>5</sup> cells/well was performed using a MOI of 50 or 100 per *H. pylori* strain (Kwok et al., 2002). After infection for 4 h, the AGS-bacterium co-cultures were washed three times with 1 ml of pre-warmed RPMI medium per
well to remove non-adherent bacteria. To determine the total number of colony forming units (CFU) corresponding to host-bound \textit{H. pylori}, the infected monolayers were incubated with 1 ml of 0.1% saponin in PBS at 37°C for 15 min. The resulting suspensions were diluted and incubated on GC agar plates as described (Kwok et al., 2002). The total CFU of cell-bound \textit{H. pylori} are given as CFU per well of AGS cells.

**CagL Peptide Synthesis**

All Fmoc-α-amino acids (9-fluorenylmethylcarbonyl-protected α-amino acids) were purchased from IRIS Biotech (Marktredwitz, Germany) and Advanced ChemTech (Louisville, USA). MALDI-ToF MS analyses were performed on a Voyager-DE (Perseptive Biosystems, Foster City, USA) using 2,5-dihydrobenzoic acid as the matrix. The analytical RP-HPLC was performed with UV detection at 220 nm and the following elution gradients: eluent A: 95% water, 5% acetonitrile, 0.1% TFA; eluent B: 95% acetonitrile, 5% water, 0.1% TFA; 0.7 ml min⁻¹, 0–5 min 100% A → 100% B; 5–6 min 100% B → 100% A; 6–6.5 min 100% A (Thermo Separation Products apparatus equipped with a Hypersil Gold (3 μm, 150 mm × 2.1 mm) column (Thermo Fisher Scientific, Waltham, USA). Preparative RP-HPLC was performed on a Thermo Separation Products apparatus equipped with a Jupiter C18 (350 Å, 10 μm, 250 mm × 21.2 mm) efficiency column (Phenomenex, Torrance, USA) with water/acetonitrile gradients as the eluent and UV detection at 220 nm. Linear peptides were synthesized by solid phase peptide synthesis on a Liberty 12 channel microwave-assisted automated peptide synthesizer (CEM, Matthews, USA) according to a Fmoc-protocol with 2-chlorotrityl resin (IRIS Biotech) as solid support. The resin loading was 0.8 mmol/g. The C-terminal resin bound amino acids were Phe for cyclopeptides-2 to -5, d-Phe for cyclopeptide-1, and Val for the linear peptide 6. Peptide coupling was performed with three equivalents of Fmoc-amino acid (0.5 M in DMF), three equivalents TBTU (1-[bis-(dimethylamino)methyl]imidazolium-3H-benzotriazol-1-oxide; 0.5 M in DMF; dimethylformamide), and six equivalents DIPEA [diisopropylethylamine; 2 M in dimethylformamide (DMF)], as described below for Western blotting.

**CIRCULAR DICHROISM SPECTROSCOPY**

Circular dichroism spectroscopy was performed on a Jasco J-810 spectrometer (Jasco, Groß-Umstadt, Germany). For the CD measurements of the CagL proteins a buffer containing 5 mM NaCl and 10 mM Na₂HPO₄ (pH 7.4) was used. The CagL WT and all mutants were measured in a 1-mm quartz cuvette, adjusted to a concentration of 3.9 nM. The secondary structure was evaluated using the deconvolution function of the Spectra Manager II Software (Jasco) based on CDPro structure analysis methods using Yang’s references (Yang et al., 1986; Sreerama and Woody, 2004).

**Antibodies and Western Blotting**

Treated/infected cells were harvested in ice-cold PBS containing 1 mM Na₃VO₄ (Sigma-Aldrich). Western blotting was done using 200 μmol of linear precursor were dissolved in 20 ml DMF, and 600 μmol HATU (1-[bis-(dimethylamino)methyl]imidazolium-1H-1,2,3-triazolo[4,5-b]pyridine-3-oxide) were dissolved in the same volume of DMF. Each solution was transferred into a syringe, and both solutions simultaneously were added to a stirred solution of 1200 μmol DIPEA and 20 μmol HATU in 10 ml DMF at a rate of 1.00 ml/h (Malesevic et al., 2004). Finally, the mixture was stirred for further 15 min, and the solvent was evaporated under reduced pressure at a temperature below 30°C. Peptide purification was carried out using preparative RP-HPLC. Deprotection of the cyclic peptides took place in a mixture of TFA (95%), TIS (trisopropylsilane; 2.5%), and water (2.5%), with shaking at room temperature for 2 h. The solvent was evaporated and cold diethyl ether (30 ml) was added to the residue. After centrifugation for 1 h at 0°C and 4000 × g, diethyl ether was decanted and the residue was dissolved in water, lyophilized, and purified by preparative RP-HPLC. The yield and purity of the synthesized peptides are given in Table 2.

**Table 2 | Characteristics of synthesized CagL peptides.**

| Peptide | Sequence | Yield (%) | Purity (%) |
|---------|----------|-----------|------------|
| 1       | c(-FEANE-) | 13.6      | >96        |
| 2       | c(-FeANE-) | 8.0       | >99        |
| 3       | c(-FesNE-) | 8.0       | >95        |
| 4       | c(-FEAnE-) | 4.0       | >99        |
| 5       | c(-FEAnE-) | 16.8      | >99        |
| 6       | ANFEANELFfISEDV | 2.1     | >94        |

*The purity of each peptide was confirmed by analytical HPLC. d-amino acids are given in small letters.*
as previously described (Tegtmeier et al., 2009). Rabbit α-CagL antiserum was raised against the C-terminal peptide (C-RSLEQSKRKYLQCER) of the protein and was prepared by Biogenes (Berlin, Germany). The α-HA-tag antibody (Invitrogen, Darmstadt, Germany) was also used to detect tagged CagL. The pan-α-phospho-tyrosine antibody PY-99 (Santa Cruz) and α-CagA (Austral Biologicals, San Ramon, CA, USA) were used to investigate the phosphorylation of CagA. The polyclonal α-phospho-ERK1/2-PT202/PY-204 antibody was purchased from NEB (Frankfurt, Germany). The polyclonal α-phospho-Cortactin-PS-405 antibody was described recently (Tegtmeier et al., 2011b).

The glyceraldehyde-3-phosphate dehydrogenase (GAPDH) antibody Lumi-Imager F1 (Roche Diagnostics, Mannheim, Germany) and corresponding kinase activities were quantitated with the antibody detection was performed with the ECL Plus chemiluminescence kit (Amersham Pharmacia Biotech). Band intensities and corresponding kinase activities were quantitated with the Lumimager F1 (Roche Diagnostics, Mannheim, Germany).

### Statistical Analysis
All data were evaluated using Student t-test with SigmaStat statistical software (version 2.0). Statistical significance was defined by $P \leq 0.05$ (*) and $P \leq 0.005$ (**). All error bars shown in figures and those quoted following the ± signs represent standard deviation.

### Results

#### Synthetic RHS-Cyclopeptides Influence WM-115 Cell Adhesion to Immobilized CagL Mutants

Previous studies indicated that the RGD sequence in CagL is important but not sufficient to trigger host cell receptor binding and signaling (Kwok et al., 2007; Tegtmeier et al., 2010; Conradi et al., 2011; Wiedemann et al., 2012). The recently published 3D homology model of CagL (Backert et al., 2008) was screened for other surface exposed amino acid sequences to further explore the hypothesis that other CagL features besides the RGD sequence might be important for integrin interactions. Among other possible motifs that are surface exposed and with an orientation that is directed to the plausible CagL–integrin interaction site, the so-called RHS motif in proximity to the RGD motif (Figure 1) was identified as a candidate for host interaction. A series of five cyclopeptides comprising the RHS sequence was designed and synthesized to mimic the exposed motif in CagL. (Figure 1). According to the spatial screening approach each of the five amino acids was mutually replaced by its α-configured counterpart to stabilize the overall conformation and increase the spatial peptide backbone diversity (Tables 2 and 3). None of the cyclopeptides-1 to -5 inhibited WM-115 cell adhesion to immobilized CagLWT (IC$_{50}$ > 1 mM; Table 3). However, WM-115 cell adhesion to the mutant CagL$_{RAD}$ was inhibited by cyclopeptide-2 [c-(-FeANE-)] with an IC$_{50}$ value in the range of 54–430 μM (Table 3). In addition, cyclopeptides-1 and -2 displayed weak inhibition of WM-115 cell adhesion to the mutant CagL$_{RGA}$ with IC$_{50}$ values of 43–340 and 30–530 μM, respectively. The other cyclopeptides-3 to -5 did not display any significant effect on the WM-115–CagL interaction (IC$_{50}$ > 1 mM; Table 3).

### A Linear RHS 15-mer Peptide Interferes with WM-115 Adhesion to the CagL$_{RAD}$ and CagL$_{RGA}$ Mutants

In addition, cell adhesion assays were performed to investigate whether the linear peptide 6 (ANFEANELFFISEDV) has effects on the adhesion of WM-115 cells to immobilized CagLWT and its RGD mutants CagL$_{RGA}$ and CagL$_{RAD}$. Linear peptide 6 mimics the RHS motif with the Phe-Glu-Ala-Asn-Glu sequence and its adjacent amino acids within the CagL protein sequence (Figure 1). According to its CD spectrum, it does not adopt a discrete conformation in solution (data not shown). While linear peptide 6 did not significantly interfere with CagLWT–WM-115 interaction in the cell adhesion assay (IC$_{50}$: > 1 mM), it exhibited a slight inhibitory activity on the CagL$_{RAD}$–WM-115 interaction (IC$_{50}$: 259 μM; CI$_{95\%}$: 164–346 μM; R$^2$: 0.88) and the CagL$_{RGA}$–WM-115 interaction with an IC$_{50}$ of 9 μM (CI$_{95\%}$: 6–15 μM; R$^2$: 0.76; Figure 2; Table 3). In comparison to the properties of the earlier mentioned c-(-RGDIA-) peptide to inhibit the WM-115 cell adhesion to CagLWT (IC$_{50}$: 2.31 μM; CI$_{95\%}$: 1.40–3.82 μM; R$^2$: 0.89) and its RGD mutants CagL$_{RGA}$ (IC$_{50}$: 1.63 μM; CI$_{95\%}$: 1.01–2.63 μM; R$^2$: 0.93) and CagL$_{RAD}$ (IC$_{50}$: 0.91 μM; CI$_{95\%}$: 0.58–1.43 μM; R$^2$: 0.94), the inhibition properties of the linear peptide 6 are obviously reduced (Table 3). Nonetheless the results support involvement of the RHS motif in CagL–WM-115 interaction.

### The Recombinant CagL Mutants are Correctly Folded

For further investigation of the RHS motif and to reveal the relevance of specific amino acids in this sequence, CagL point mutants were recombinantly produced in E. coli, where individual amino acids were replaced by alanine residues (Table 4). CD spectroscopy was used to verify the correct folding of the mutants CagL$_{F66A}$, CagL$_{E87A}$, CagL$_{E87A/A88F}$, and CagL$_{E90A}$ in comparison to CagLWT. The secondary structure composition calculated for CagLWT is in good accordance with the proposed CagL homology model (Backert et al., 2008) and displays a high content of α-helices (~35%), accompanied by β-strands (~29%), Figure 3A). The mutants CagL$_{F66A}$, CagL$_{E87A}$, CagL$_{E87A/A88F}$, and CagL$_{E90A}$ CD spectra display comparable curve shapes like the CagLWT (Figure 3D). Unfortunately, the amount of CagL$_{N99A}$ protein necessary to estimate the secondary structure and to validate the correct protein folding with CD spectroscopy could not be obtained and, therefore, could not be included in the study. However, to obtain information on the structural stability and to further compare the CagL$_{E87A}$ and CagL$_{E90A}$ mutants with CagLWT, temperature-interval dependent CD measurements were performed ranging from 0 to 60°C (Figures 3A–C). In general, all tested proteins behaved in similar manner, exhibiting temperature-dependent denaturation above 40°C. Below 40°C, the secondary structures are comparable, with only minor structural differences. In comparison, the CagL$_{E90A}$ CD spectrum shows maximum deviations at temperatures below 20°C (Figure 3C). In addition, we performed a pH screening by measuring the CD spectra of CagLWT over a pH range from four to nine in phosphate buffer and could show that the protein is very stable under the tested conditions (Figure 3E).

### WM-115 Cell Adhesion Studies with CagL RHS Mutants

Different CagL mutants with amino acid variations in the RHS motif (CagL$_{F66A}$, CagL$_{E87A}$, and CagL$_{E90A}$) were immobilized...
and investigated in cell adhesion assays. The WM-115 cells were pre-incubated with the previously described cyclopeptide-7 [c-(Arg-Gly-Asp-d-Leu-Ala-)] in different concentrations from nanomolar to millimolar ranges to block the RGD-binding site of the integrins. The dose–response curves obtained in these assays are shown in Figure 4. For comparison, the cell adhesion results of the recently published CagLWT, CagLRG, and CagLRAD mutants are also given in Table 4 (Conradi et al., 2011). Additionally, the CagLQ40A mutant was included as a negative control to exclude the possibility that genetic mutations in the CagL sequence may

Figure 2 | Dose–response curve of a linear RHS motif-containing peptide, inhibiting binding of WM-115 cells to immobilized CagL<sub>WT</sub> and mutants. The WM-115 cells were pre-incubated in different concentrations of the linear 15-mer peptide ANFEANELFFISEDV, which mimics the exposed RHS motif of CagL. Purified CagL<sub>WT</sub> and the CagL<sub>RAD</sub> and CagL<sub>RGA</sub> mutants were immobilized on plastic surface followed by addition of the WM-115 cells. After 1 h of co-incubation, the amounts of attached cells were determined. The data were evaluated using non-linear fit for the evaluation of the potency of peptide ANFEANELFFISEDV to inhibit the binding of WM-115 cells to immobilized CagL.

Figure 4 | showing also comparable to the values observed for CagL<sub>RGA</sub> (0.91 μM; Figure 4; Table 4). In an additional experiment we tested the double mutant CagL<sub>EB7A/ABBE</sub> to reveal more details on the involvement of CagL amino acid Glu<sup>87</sup> in the interaction with WM-115 cells. The double mutant CagL<sub>EB7A/ABBE</sub> formally is characterized by the shift of an acidic amino acid side chain from position 87 to position 88. The immobilized CagL<sub>EB7A/ABBE</sub> protein displayed no binding to the WM-115 cells, which may indicate a loss of integrin affinity. In conclusion, the results show remarkably reduced adhesion of WM-115 cells to immobilized CagL<sub>EB7A</sub> and CagL<sub>EB90A</sub> compared to the CagL<sub>WT</sub>, which implies a participation of the glutamates in the CagL–WM-115 interaction.

PEPTIDE ARRAY MAPPING OF THE CagL RHS MOTIF FOR INTEGRIN BINDING

The previously described SPOT technique (Frank, 2002) was applied to identify the CagL amino acid sequence responsible for binding to integrin α5β1. Overlapping linear 15-mer peptides derived from the CagL sequence from amino acid position 60–104 were chemically synthesized on a cellulose membrane by the SPOT method (Frank, 1992). As shown in Figure 5A, adjacent peptides share the same sequence of 12 amino acids but differ by three amino acids at the C- or N-terminal ends, respectively.
FIGURE 3 | Structural evaluation of purified CagL proteins with CD spectroscopy. (A) The CagL<sup>WT</sup> secondary structure was evaluated as described previously (Yang et al., 1986). (A–C) The temperature-dependent structure stability of the mutants CagL<sub>E87A</sub>, CagL<sub>E90A</sub>, and the CagL<sup>WT</sup> protein was evaluated in CD measurements. (D) Secondary structure of CagL<sup>WT</sup> and mutants CagL<sub>F86A</sub>, CagL<sub>E87A</sub>, CagL<sub>E87A/E88E</sub>, and CagL<sub>E90A</sub> were evaluated to control correct folding of the proteins after expression and purification. (E) pH stability of CagL<sup>WT</sup> in the pH range four to nine.
Conradi et al. RGD helper motif in CagL

Purified integrin α5β1 was incubated with these membranes and the binding was assayed as described in the Section “Materials and Methods.” Figure 5B shows that integrin α5β1 binds to the RGD motif-containing arraypeptides-3 and -4. In addition, a very strong signal for arraypeptide-9 covering the RHS motif was recorded (Figure 5B, top and Figure 5C). Interestingly, two other FEANE sequence-containing array peptides (-7 and -8) did not bind integrin α5β1, suggesting that the flanking C-terminal sequences are also important for this interaction. As a control, incubation of the membranes with two other integrins, αvβ3 and αvβ5 also revealed signals for the two RGD containing CagL peptides and some weak signals for arraypeptides-10 or -11, respectively (Figure 5B, middle and Figure 5C). The mock control blot revealed no signals as expected (Figure 5B, bottom).

GENERATION OF RHS POINT MUTATIONS OF CagL IN H. PYLORI
To investigate the importance of the RHS motif in CagL directly during infection with H. pylori, two CagL mutants were generated carrying the A84E/E87A and A88E/L91A point mutations. Based on the above described peptide array the two point mutants were constructed to contain one mutation in the RHS sequence and one either N- or C-terminal, to cover additional amino acids that may be relevant for host cell interactions. CagLWT and both mutants were chromosomally integrated into a P12ΔcagL deletion mutant and expressed as HA-tag fusions in the ureA locus as described (Shaffer et al., 2011). The correct expression of each of these CagL variants was verified by Western blotting using an α-HA antibody (Figure 6A). The AGS cells were infected with each of these H. pylori strains for 4 h, followed by analysis of viable bacterial binding to cells, as described in Materials and methods. The results show that each of these strains bound to AGS cells with high efficiency. Some minor differences in binding were seen among the different strains but were not statistically significant (Figure 6B). This suggests that mutation of the RHS motif in CagL has no significant inhibitory impact on the overall capacity of the bacteria to bind to AGS host cells.

MUTATION OF THE RHS MOTIF INHIBITS CagA PHOSPHORYLATION AT EARLY TIMES OF INFECTION
AGS cells were infected with the different complemented H. pylori strains during a time course of 2 and 4 h, respectively, to investigate whether strains expressing CagL mutant proteins can trigger the
injection and phosphorylation of CagA. The results of the α-phospho-tyrosine and α-CagA specific Western blots show that P12ΔcagL re-expressing CagLWT can efficiently inject and phosphorylate CagA in a time-dependent fashion (Figures 7A,B). Infection of AGS with P12ΔcagL expressing the CagLΔA84E/E87A mutant revealed a ~46% reduced phospho-CagA signal at 2 h, while very strong phospho-CagA signals were produced at the 4-h time point with almost no difference as compared to the complemented CagLWT control (Figures 7A,B). This suggests that mutation of A84E/E87A in CagL affects the injection and phosphorylation of CagA at very early times of infection. In contrast, infection with H. pylori expressing the CagLΔA88E/L91A mutant revealed a stronger reduction of phospho-CagA signals (~69%) at 2 h as compared to the complemented CagLWT control, while this low level of phospho-CagA did only slightly increase after 4 h of infection (Figures 7A,B). This result shows that a strain expressing the CagLΔA88E/L91A mutant protein has a significant defect in injection and phosphorylation of CagA at both time points of infection.

**Mutation of the RHS Motif Exhibits Significant Signaling Defects in H. pylori-Induced ERK1/2 Activation**

Finally the various RHS mutations in CagL were inspected in relation to impacts on cellular downstream signaling involved in the H. pylori-induced AGS cell elongation phenotype. It was recently shown that besides CagA phosphorylation, the activation of the ERK1/2 MAP kinase pathway either by H. pylori infection (Mimuro et al., 2002; Tegtmeier et al., 2009) or by transfection CagA in the absence of H. pylori (Higashi et al., 2004) is also crucial for phenotypical outcome. Therefore, we tested whether the different CagL-expressing H. pylori strains induced the activation of ERK1/2, using the same conditions as described for Figure 7. The results of the α-phospho-ERK1/2 Western blots show that P12 WT or P12ΔcagL re-expressing CagLWT (but not P12ΔcagL) can efficiently activate this MAP kinase in a time-dependent fashion (Figures 8A,B). Infection of AGS with H. pylori expressing the complemented CagLΔA84E/E87A mutant revealed a significantly (46%) reduced phospho-ERK1/2 signal at 2 h, and a similarly reduced (38%) phospho-ERK1/2 signal at 4 h time point as compared to the complemented CagLWT control (Figures 8A,B). This suggests that mutation of A84E/E87A in CagL downregulates not only the injection and phosphorylation of CagA, but also reduced the activation of ERK1/2. In addition, infection with H. pylori expressing the CagLΔA88E/L91A mutant revealed an even stronger reduction of phospho-ERK1/2 signals by about 63 or 70% at the 2- or 4-h time points, respectively. This result indicates that the CagLΔA88E/L91A mutant has a significantly pronounced defect in activating ERK1/2 during infection.

**Mutation of the RHS Motif Results in Reduced Cortactin Serine Phosphorylation and AGS Cell Elongation**

Very recently, we demonstrated that one important downstream target of activated ERK1/2 during infection is the actin-binding protein cortactin, phosphorylated at serine residue 405 (Tegtmeier et al., 2011b). Hence it was tested whether the various CagL-expressing strains induce the phosphorylation of cortactin at S-405 during a time course of 2 and 4 h infection. The results of the α-phospho-cortactin Western blots show that P12 WT or P12ΔcagL re-expressing CagLWT but not P12ΔcagL can efficiently activate cortactin 2- or 4-h time points, respectively. This suggests that mutation of A84E/E87A in CagL downregulates not only the injection and phosphorylation of CagA, but also reduced the activation of ERK1/2. In addition, infection with H. pylori expressing the CagLΔA88E/L91A mutant revealed an even stronger reduction of phospho-cortactin signals by about 63 or 70% at the 2- or 4-h time points, respectively. This result indicates that the CagLΔA88E/L91A mutant has a significantly pronounced defect in activating ERK1/2 during infection.
phospho-cortactin signal at the 4-h time point (Figures 8A,B). This suggests that mutation of CagL in the RHS motif (either A84E/E87A or A88E/L91A mutations) downregulates cortactin's serine phosphorylation to a similar high extent at the 4-h time point, indicating that the CagL\textsuperscript{A84E/E87A} and CagL\textsuperscript{A88E/L91A} mutants share a significantly pronounced defect in activating cortactin during infection. Finally, the elongation phenotype was monitored in the same set of experiments. As shown in Figure 8C, mutation of the RHS motif at A84E/E87A or A88E/L91A inhibited the elongation phenotype by more than 50% at the 2-h time point. At the 4-h time point, the CagL\textsuperscript{A84E/E87A} mutant exhibited a \( \approx 20\% \) reduction and the CagL\textsuperscript{A88E/L91A} mutant revealed a \( \approx 43\% \) reduction as compared to the complemented CagL\textsuperscript{WT} control. This set of experiments reveals that mutation of the RHS motif in \textit{H. pylori} results in significant defects in signaling to cortactin and cell elongation, especially at very early times of infection.

**DISCUSSION**

Our previous studies have suggested that the RGD sequence is an important structural motif in the \textit{H. pylori} CagL pilus protein, able to trigger T4SS-mediated host cell binding and signaling, but this sequence alone is not sufficient (Kwok et al., 2007; Tegtmeier et al., 2010; Conradi et al., 2011; Wiedemann et al., 2012). Thus, we examined the 3D structural CagL model (Backert et al., 2008) to identify other potential surface exposed CagL–integrin interaction motifs. In this study, we report on the discovery of a novel motif in CagL, called RHS consisting of a Phe-Glu-Ala-Asn-Glu core sequence, which also plays a role in the interaction with host cell antibodies. The \( \alpha \)-GAPDH blot served as loading control in each sample.

**FIGURE 7** Effects of CagL point mutations in the RHS motif on CagA injection and phosphorylation during \textit{H. pylori} infection of AGS cells. (A) The P12\textsubscript{ΔcagL} deletion mutant was complemented with CagL\textsuperscript{WT} or various CagL point mutants. AGS cells were infected with the different indicated \textit{H. pylori} strains (MOI = 100) during a time course of 2 or 4 h, respectively. The resulting protein lysates were subjected to Western blotting using \( \alpha \)-phospho-tyrosine (PY-99) and \( \alpha \)-CagA antibodies. The \( \alpha \)-GAPDH blot served as loading control in each sample. (B) Quantification of CagA phosphorylation. Densitometric measurement of individual band intensities of the \( \alpha \)-CagA and \( \alpha \)-phospho-tyrosine (PY-99) blots in (A) was performed with the Lumi-Imager F1 (Roche). Quantification revealed the relative amount of phospho-CagA per sample in %. Similar inhibitory activities of all mutants were seen when MOI = 50 was used (not shown).
FIGURE 8 | Mutation of CagL in specific amino acids within the RHS motif results in defects in $H.\ pylori$-triggered ERK1/2 activation, cortactin phosphorylation, and AGS cell elongation. (A) AGS cells were infected with the different complemented $H.\ pylori$ strains (MOI = 100) during a time course of 2 or 4 h, respectively. The same protein lysates as shown in Figure 7 were subjected to Western blotting using the indicated $\alpha$-phospho-ERK1/2 and $\alpha$-phospho-cortactin antibodies.

(B) Densitometric measurement of individual band intensities of the blots in (A) and comparison to total $\alpha$-ERK1/2 and $\alpha$-cortactin blots (not shown) was performed with the Lumi-Imager F1 (Roche). The relative amounts of phospho-ERK1/2 and phospho-cortactin per sample were quantified and given in %.

(C) Quantification of the AGS cell elongation phenotype in the same set of experiments. Similar inhibitory activities of all mutants were seen when MOI = 50 was used (not shown).

integrins. A peptide array of overlapping 15-mer peptides derived from the CagL primary structure showed that peptides containing the RHS motif of CagL can bind particularly to integrin $\alpha_5\beta_1$, whereas they bind only weakly to other integrins, such as $\alpha_6\beta_3$ and $\alpha_6\beta_5$. Further studies, including the use of CagL-derived peptides in competitive WM-115 cell binding assays, and the analysis of recombinant CagL point mutants in cell binding in vitro and during infection of AGS cells with $H.\ pylori$, collectively indicated that the RHS sequence plays an important role in the interaction of CagL with host cells.

The spatial screening approach (Haubner et al., 1996; Weide et al., 2007) was employed with five conformationally designed synthesized cyclopeptides-1 to -5, wherein each of the five amino acids was mutually replaced by its D-configured correlate to mimic the RHS sequence of CagL. Receptor binding of such cyclopeptides is regarded to be entropically favored, if the receptor-bound
conformation is still accessible. However, neither the linear RHD-peptide 6 (ANFEANELFFFISEDV) nor the RHS-cyclopeptide-1 to -5 showed a significant effect on WM-115 cell adhesion to immobilized CagLWT. In contrast, RGD-dependent WM-115 cell adhesion could be efficiently influenced by the RGD-cyclopeptide-7. Mutations within the RGD sequence in extracellular matrix proteins such as fibronectin are usually accompanied by loss of integrin affinity (Giancotti and Ruoslahti, 1999; Takahashi et al., 2007; Leiss et al., 2008). This seems not to be fully applicable to CagL, as integrin-expressing WM-115 cells still adhere to the mutated proteins CagLRAD and CagLRGA but with reduced affinity (Conradi et al., 2011). Interestingly, both the linear RHD-peptide ANFEANELFFFISEDV and the RHD-cyclopeptide-2 were able to interfere with WM-115 cell adhesion to immobilized CagL RGA and CagL RAD proteins with IC50 values in the micromolar range, indicating significant binding. The studies with the CagL RGA and CagL RAD mutants allowed us to distinguish RGD-dependent interaction from other types of binding. Not all RHS-cyclopeptides displayed such inhibitory biological activity, which clearly proves the influence of peptide conformation and three-dimensional structure on the anti-adhesive properties. We thus conclude that the WM-115 cell adhesion to recombinant CagL is mainly driven by the RGD recognition sequence, but is significantly assisted by the RHS sequence as a proposed auxiliary motif. There is an interesting analogy to fibronectin. Besides the RGD motif, fibronectin harbors another sequence required for maximum binding affinity to integrin α5β1, called the synergy region, located in the ninth type III module adjacent to the RGD site (Nagai et al., 1991; Aota et al., 1994; Bowditch et al., 1994; Chada et al., 2006). Subsequent studies showed that the synergy region is not directly in contact with the integrin α5β1 bound to fibronectin, and proposed an indirect function of the synergy region for the high affinity binding by optimally exposing the flexible RGD motif or by inducing long range electrostatic steering (Baron et al., 1992; Takagi et al., 2003).

In the case of CagL, however, a FEANE-containing peptide alone can bind integrin α5β1 as shown in peptide arrays, and the synergy region of fibronectin shares no sequence homology to CagL or the RHS domain. The role of the RHS motif and neighboring amino acids was further investigated on the protein level with recombinant CagL proteins carrying corresponding point mutants. The secondary structure and temperature stability of all generated point mutants corresponds with that observed for CagLWT according to CD spectra. Given the above assumptions, pre-incubation of the WM-115 cells with the RGD-cyclopeptide-7 should provide information on the contribution of the RHS sequence to CagL binding phenomena. Strikingly, there is an effect of mutations in the RHS motif of CagL on WM-115 cell adhesion. RGD-cyclopeptide-7 was able to inhibit cell adhesion to CagL with mutations in the RHS sequence (CagL F86A, CagL E87A, CagL E90A) even at lower concentrations than for CagLWT. Granted that cell adhesion is governed by both RGD and RHS sequences, a mutation in the CagL RHS sequence (CagL RGA, CagL RAD) would lead to reduced cell adhesion and, hence, require a smaller concentration (reduced IC50) of the RGD-peptide that competes for binding (Table 4; Conradi et al., 2011). Conversely, WM-115 cell adhesion to immobilized CagL with mutations in the RHS motif conferring decreased affinity could be inhibited by the RGD-peptide at a smaller concentration (reduced IC50). This was indeed observed for CagL E87A and CagL E90A. In conclusion, the point mutant CagL F86A and a control mutant CagL Q40A show no significant affinity loss in their binding to WM-115 cells as compared to CagLWT, while the point mutants CagL E87A and CagL E90A display remarkably reduced affinity to WM-115 cells. The replacement of the negatively charged glutamates E87 and E90 by the hydrophobic amino acid alanine resulted in a decreased affinity toward WM-115 cells. In contrast, the exchange of the uncharged amino acids phenylalanine F86 and glutamine Q40 by alanine did not have any consequence in the same assays. These data imply that especially glutamate E87 is important for the interaction with integrin on the surface of host cells.

At first sight, the peptide array experiments in which we investigated the binding of immobilized CagL 15-mer peptides with the different purified integrins seem to implicate a stronger signal of a RHS containing peptide for bound integrin α5β1, but much weaker signals compared to RGD containing peptides on the same membrane. Regarding the conformation of RGD containing peptides, cyclic RGD peptides with a β-turn around Asp–n-Leu–Ala–Arg display a much higher affinity to some integrins than do linear RGD peptides. The linear RGD containing peptides do not prefer this structural β-turn conformation, which could explain the fact that linear RGD peptides on the peptide array display very little affinity to integrins as compared to their cyclopeptide counterparts. While the array-peptides-7 to -9 contain the whole FEANE amino acids of the RHS motif, only array-peptide-9 reveals integrin β1 interaction (Figure 5). In array-peptide-10 and -11 the 15-mer peptide sequence is shifted C-terminally for three amino acids. Array-peptide-10 therefore is lacking the phenylalanine of the RHS motif and displays a different interaction with integrin subunit β3, while the array-peptide-11 includes only the final glutamate of the RHS motif and displays weak interaction with the integrin β3 subunit. In cell binding studies with the 15-mer peptide of array-peptide-9 corresponding to linear peptide 6, a binding inhibition of WM-115 cells to immobilized CagL RAD and CagL RGA could be shown (Tables 2 and 3). Overall the binding potency of this linear peptide was surprisingly better than that observed for the cyclic RGD peptides. These results emphasize the possible involvement of adjacent amino acids next to the FEANE sequence for integrin interactions that probably are located in the C-terminal flanking site. The presented results allow no complete elucidation of amino acids important for integrin interaction, but combining the results of cell binding studies and the peptide array, the CagL F86 amino acid is not involved in the interaction with WM-115 cells (Table 3) and the interaction with purified integrins (Figure 5), while both glutamates E87 and E90 have an impact and are probably exposed on the CagL surface. The observed binding of three different integrins to a relatively small CagL sequence region of about 18 amino acids on peptide arrays is a very interesting finding, and is relevant to recent reports which showed that CagL interacts not only with integrin α5β1 on cells, but also αvβ3 and αvβ5 (Kwok et al., 2007; Conradi et al., 2011; Wiedemann et al., 2012).

Finally, it was investigated if the newly discovered RHS motif in CagL might also play a role during infections with H. pylori.
As discussed above, an explicit amino acid region for the so-called RHS motif could not be clearly defined. Therefore two double point mutants CagL$_{A84E/E87A}$ and CagL$_{A86E/L91A}$ were chosen, with one mutation in the RHS region and another located at the N- or C-terminus, respectively. Based on infection experiments, we could show that H. pylori P12 WT, deletion mutant P12ΔcagL, and P12ΔcagL re-expressing CagLWT or CagL point mutants (A84E/E87A and A86E/L91A) bound equally well to cultured AGS cells. This suggests that CagL is not involved in general host cell binding during infection, in agreement with previous reports showing the overall importance of the major canonical adhesins BabA/B, SabA, AlpA/B, or OipA (for review, see Tegtmeier et al., 2011a). However, this illustrates clearly that the observed signaling defects discussed below are not due to a more general deficiency of the bacteria to adhere to AGS cells. First, $H$. pylori expressing the generated CagL point mutants exhibited significant defects in infection and phosphorylation of CagA between 2 and 4 h of infection. Second, each of the CagL mutants in $H$. pylori had significantly pronounced defects in activating the MAP kinases ERK1/2 and serine phosphorylation of cortactin as well as $H$. pylori had significantly pronounced defects in activating the MAP kinases ERK1/2 and serine phosphorylation of cortactin as well as the induction of the AGS cell elongation phenotype during infection. This suggests that mutation of the RHS motif in $H$. pylori results in various defects in the interaction of CagL with integrin $\alpha_5\beta_1$, with resulting inhibitory consequences for (i) the injection of CagA and (ii) for the downstream signaling to ERK1/2 and cortactin triggering cell elongation, especially at early times of infection.

Taken together, our presented data provide evidence for a novel domain in CagL playing a significant role in binding to integrin $\alpha_5\beta_1$ in vitro and for initiating signaling pathways through certain motifs encoded in the so-called RHS motif comprising the FEANE sequence and its flanking amino acids. We propose that the RGD motif is important for the CagL binding to integrins, while subsequent binding of other integrin-specific CagL motifs may assist in certain intracellular signaling events. Although we could demonstrate that the RHS motif and its adjacent amino acids are relevant in CagL–integrin interactions and have an impact on the resulting signaling, more studies are necessary to further define the specific amino acids relevant for integrin interaction and downstream signaling. In addition, it has been shown that beside CagL, multiple other $H$. pylori factors are also involved in integrin $\beta_1$ binding, including CagA, CagL, CagY, and possibly CagH (Kwok et al., 2007; Jimenez-Soto et al., 2009; Shaffer et al., 2011). Their individual role for integrin-targeting/binding is not yet fully clear. Future studies should investigate whether these proteins act together or at different stages of the infection process.

Chem. 269, 10856–10863. Chada, D., Mather, T., and Nollert, M. U. (2006). The synergy site of adhesins BabA/B, SabA, AlpA/B, or OipA (for review, see Tegtmeier et al., 2011a). However, this illustrates clearly that the observed signaling defects discussed below are not due to a more general deficiency of the bacteria to adhere to AGS cells. First, $H$. pylori expressing the generated CagL point mutants exhibited significant defects in infection and phosphorylation of CagA between 2 and 4 h of infection. Second, each of the CagL mutants in $H$. pylori had significantly pronounced defects in activating the MAP kinases ERK1/2 and serine phosphorylation of cortactin as well as the induction of the AGS cell elongation phenotype during infection. This suggests that mutation of the RHS motif in $H$. pylori results in various defects in the interaction of CagL with integrin $\alpha_5\beta_1$, with resulting inhibitory consequences for (i) the injection of CagA and (ii) for the downstream signaling to ERK1/2 and cortactin triggering cell elongation, especially at early times of infection.

Taken together, our presented data provide evidence for a novel domain in CagL playing a significant role in binding to integrin $\alpha_5\beta_1$ in vitro and for initiating signaling pathways through certain motifs encoded in the so-called RHS motif comprising the FEANE sequence and its flanking amino acids. We propose that the RGD motif is important for the CagL binding to integrins, while subsequent binding of other integrin-specific CagL motifs may assist in certain intracellular signaling events. Although we could demonstrate that the RHS motif and its adjacent amino acids are relevant in CagL–integrin interactions and have an impact on the resulting signaling, more studies are necessary to further define the specific amino acids relevant for integrin interaction and downstream signaling. In addition, it has been shown that besides CagL, multiple other $H$. pylori factors are also involved in integrin $\beta_1$ binding, including CagA, CagL, CagY, and possibly CagH (Kwok et al., 2007; Jimenez-Soto et al., 2009; Shaffer et al., 2011). Their individual role for integrin-targeting/binding is not yet fully clear. Future studies should investigate whether these proteins act together or at different stages of the infection process.

ACKNOWLEDGMENTS

The work of Steffen Backert was supported through Priority Program SPP1150 of the Deutsche Forschungsgemeinschaft DFG (Ba1671/3) and another DFG grant (Ba1671/8-1). Timothy L. Cover was supported by the National Institutes of Health (R01 AI068009 and P01 CA116087) and the Department of Veterans Affairs. We thank Sabine Brandt (University Magdeburg) for support in the peptide array hybridizations, and Carrie Shaffer (Vanderbilt University Nashville) for help with the CagL/peptide complementation plasmid.
