The study of the effect of ethyl alcohol concentrations on the antioxidant activity of ascorbic acid solutions

Much attention is currently paid to the study of the antioxidant properties of various objects – individual antioxidants, dietary supplements, medicines, liquid plant extracts. Antioxidant medicines are widely used as the main or additional correction agents in the treatment of a number of diseases. Therefore, the study and development of procedures for determining the antioxidant activity is a prospective task for today.

**Aim.** To determine the contribution of different concentrations of ethanol to the level of the antioxidant activity (AOA) of ascorbic acid solutions by the potentiometric method.

**Results and discussion.** The different ethanol content in the solution had the following percent of the contribution to the value of AOA of ascorbic acid solutions – 1.85, 3.56, 4.89, 6.76, 7.63% for 20, 40, 60, 80, 96% ethanol, respectively. The linearity of the procedure was proven in the range from 0.039 to 0.31 mmol/L.

**Experimental part.** The object of the study was solutions of ascorbic acid prepared using ethanol of different concentrations – 20, 40, 60, 80, 96%. Potentiometric measurements were conducted by a Hanna 2550 pH meter (Germany) with an EZDO 5010 combined platinum electrode. Weighing was carried out using an AN100 digital analytical balance (AXIS, Ukraine) with d = 0.0001 g. Ascorbic acid was purchased from Sigma Aldrich (≥99.0%), K,[Fe(CN)]_6, K,[Fe(CN)]_6·NaHPO_4, KH.PO were of analytical grade.

**Conclusions.** It has been found that ethyl alcohol affects the change of the potential in the electrochemical cell and the level of AOA of ascorbic acid solutions. The percentage of the contribution of different concentrations of ethanol to the AOA value ranges from 1.85 to 7.63%. The approach and the formula for calculation that take into account the effect of ethyl alcohol on the final AOA result of the test sample of ascorbic acid in a water-alcohol solutions have been proposed. The results of this study can be used in the pharmaceutical and food industries to determine, assess and control the AOA level of dietary supplements, liquid extracts, tinctures, medicines, and alcoholic beverages.

**Key words:** effect of ethanol; ascorbic acid; antioxidant activity; potentiometric method
Free radicals are the main cause of the development of such serious diseases as radiation sickness, atherosclerosis, myocardial infarction, diabetes, cancer diseases. Living cells have a perfect antioxidant defense system that regulates the formation of free radicals (FR) and limits their accumulation in cells. Nevertheless, sometimes it is not enough, and therapy with the inclusion of antioxidants (AO) is increasingly used in the treatment of a number of diseases. Therefore, the production of branded antioxidants, including various components of natural or synthetic origin, is expanding [1].

Methods for studying the total antioxidant activity (AOA) can be divided by the type of the oxidation source, the oxidized compound, and the method of measuring AOA. In practice, the antioxidant activity is determined when conducting nonselective reactions with an oxidant, generating radicals, and measuring the electrochemical, kinetic, optical and other properties of indicator systems in the course of the reactions [2].

Electrochemical methods of analysis are based on the donor-acceptor reactions between AO and FR. Single-electron transfer methods are characterized by high sensitivity, the rapid analysis procedure, a relatively low cost of equipment and reagents, and hence, the analysis as a whole [3]. These methods include the potentiometric method based on the chemical interaction of AO with a mediator system, which is a mixture of K₄[Fe(CN)₆]/K₃[Fe(CN)₆] [4]. Addition of solutions containing substances exhibiting AOA to the cell leads to a change in the redox potential of the medium as a result of the interaction of AO with the oxidizing component K₃[Fe(CN)₆] of the mediator system [5, 6]. In some research works [7, 8] the determination of the AOA level of alcohol extracts of plants and fungi by the potentiometric method without studying the effect of ethyl alcohol concentration on the value of AOA was described. In our view, these results can be untrue as ethyl alcohol can be oxidized also and affect the value of AOA.

In order to find out the effect of the ethyl alcohol concentration on the AOA value, ascorbic acid was chosen as a model compound, for the following reasons. Firstly, ascorbic acid is a part of numerous tinctures, for example, a tincture from lemon grass seeds, and secondly, it is relatively readily dissolved in water, and in solutions of ethyl alcohol in various concentrations. Hence, the aim of the current study is to determine the contribution of different concentrations of ethanol to the AOA level of ascorbic acid solutions by the potentiometric method.

Materials and methods

K₄[Fe(CN)₆], K₃[Fe(CN)₆], KH₂PO₄, Na₂HPO₄·12H₂O were of analytical grade, ascorbic acid was ≥99.0% (Sigma-Aldrich).

Potentiometric measurements were conducted by a Hanna 2550 pH meter (Germany) with an EZDO 5010 combined platinum electrode.

Preparation of the model solutions of ascorbic acid
Six model solutions of ascorbic acid with the concentration of 0.002 mol/L were prepared by dissolving 0.087 g of ascorbic acid in 250.0 mL of distilled water or water/ethanol mixtures with the ethanol concentrations of 20, 40, 60, 96%.

To assess linearity, different aliquots of the model solutions of ascorbic acid were taken (1.00; 3.00; 5.00; 7.00; 9.00 mL) after that each aliquot was placed in the electrochemical cell, and as the result, solutions with ascorbic acid concentrations of 0.039, 0.11, 0.18, 0.25, 0.31 mmol/L, respectively, were obtained.

The procedure of determining AOA
A 2 mmol/L solution of K₄[Fe(CN)₆] was prepared by weighing 0.8232 g into a 25.0 mL volumetric flask, dissolving the compound in distilled water and diluting to the volume with the same solvent. A 0.02 mmol/L solution of K₃[Fe(CN)₆] was prepared by weighing 0.0921 g into a 250.0 mL volumetric flask, dissolving the compound in distilled water and diluting to the volume with the same solvent. Then a 5.00 mL aliquot of both solutions prepared was taken and transferred into a 250.0 mL volumetric flask and diluted to the volume with the phosphate buffer solution of 0.067 mol/L concentration. 50.00 mL of the mediator solution prepared was transferred to the electrochemical cell. The initial potential of the mediator solution was measured. After the initial potential was determined, 1.00 mL of the aliquot of the solutions of ascorbic acid prepared was added, and a final potential was measured. Thus, the difference (∆E) between the initial (E₀) and final (Eₐ) potentials was found. The shift of the potential is explained by the change of ratio of the oxidized and reduced forms of the mediator system as a result of the following chemical reaction:

\[ a[Fe(CN)_6]^{3-} + b\text{AO} = a[Fe(CN)_6]^{4-} + b\text{AO}_{\text{ox}} \]

where: \( \text{AO} \) – is the antioxidant; \( \text{AO}_{\text{ox}} \) – is an oxidized form of the antioxidant; \( a, b \) – are stoichiometric coefficients.

The antioxidant activity was calculated by the following equation and expressed in μmol/L:

\[ \text{AOA} = \frac{C_{\text{ox}} - \alpha \cdot C_{\text{red}}}{1 + \alpha} \times K_{\text{diff}} \times 10^6, \]

where: \( \alpha = C_{\text{ox}} / C_{\text{red}} \times 10^{\Delta E/2.303} \); \( C_{\text{ox}} \) is 0.002 mol/L of K₄[Fe(CN)₆]; \( C_{\text{red}} \) is 0.00002 mol/L of K₃[Fe(CN)₆]; \( \Delta E \) is the change of the potential; \( F = 96485.333 \text{ C/mol} \) – is the Faraday constant; \( n = 1 \) – is the number of electrons in the electrode reaction; \( R = 8.314 \text{ J/(mol} \times \text{K}) \) – is the universal gas constant; \( T = 298 \text{ K} \); \( K_{\text{diff}} \) – is the coefficient of dilution.

Statistical analysis
The statistical analysis was performed in Microsoft Excel 2010 with the accepted significance level of \( \alpha = 0.05 \). Results were expressed as the mean±conditional interval from five measurements.
Results and discussion

When determining AOA of ascorbic acid AOA of ethyl alcohol with different concentrations was also studied. As a result, Fig. 1 shows that with an increase in the concentration of ethyl alcohol in the electrochemical cell the change in the potential also increases. In addition, in the case of solutions of ascorbic acid prepared using ethyl alcohol solutions of different concentrations the same situation can be observed. This is a clear evidence that ethanol interacts with $K_3[Fe(CN)_6]$ and affects the determination of the AOA level of ascorbic acid solutions.

The contribution of ethyl alcohol can be explained by the fact that the hydroxyl group presented in its structure can be oxidized by $K_3[Fe(CN)_6]$ to give the aldehyde group. As a result, the oxidation of ethanol leads to the extra contribution in the AOA value of ascorbic acid solutions. Hence, when determining AOA by the potentiometric method the contribution of ethyl alcohol and its concentration should be taken into account.

In order to “extract” the true value of ascorbic acid AOA from the total change of the potential obtained during the analysis of the sample, the latter should be reduced by an amount corresponding to the concentration of ethyl alcohol in the sample analyzed. According to the results obtained ethanol in different concentrations has the following percent of contribution to AOA: 1.85, 3.56, 4.89, 6.76, 7.63 % for 20, 40, 60, 80, 96 % ethanol, respectively. According to this, 96 % ethanol has the greatest effect on determining AOA, whereas 20 % ethanol possesses the lowest one. The results obtained are given in the Table.

Therefore, to calculate the AOA value of the test sample (liquid extract, tincture, individual substances prepared in aqueous-alcohol and alcohol-aqueous solutions) the following equation, including the ethanol contribution, should be used:

$$\text{AOA} = \frac{C_{\text{ox}} - \alpha \cdot C_{\text{red}}}{1 + \alpha} \times K_{\text{diff}} \times 10^6,$$

where $\alpha = C_{\text{ox}}/C_{\text{red}} \times 10^{(\Delta E - E_{\text{ethanol}})/2.3RT}$, $C_{\text{ox}}$ is the concentration of $K_3[Fe(CN)_6]$, mol/L; $C_{\text{red}}$ is the concentration of ascorbic acid, μmol/L.

The results of determining AOA of the solutions of ascorbic acid

| Solvent | water | 20% | 40% | 60% | 80% | 96% |
|---------|-------|-----|-----|-----|-----|-----|
| $\Delta E$ of ascorbic acid solutions, mV | 30 | 31.1 | 32.2 | 33.1 | 34.5 | 35.2 |
| $\Delta E$ of ethanol solutions, mV | 0 | 1.1 | 2.2 | 3.1 | 4.5 | 5.2 |
| AOA without taking into account ethanol, μmol/L | 3449 ± 7.42 | 3515 ± 10.43 | 3577.5 ± 5.17 | 3627.5 ± 16.39 | 3700 ± 17.15 | 3735 ± 11.18 |
| AOA minus the contribution of ethanol, μmol/L | 0 | 65 | 127.5 | 177.5 | 250 | 285 |
| Contribution of ethanol, % | 0 | 1.85 | 3.56 | 4.89 | 6.76 | 7.63 |
of K[Fe(CN)₆], mol/L; \(E = (0.0546 \times C_{\text{ethanol}}) - 0.0091\) taken from Fig. 1; \(C_{\text{ethanol}}\) – is the concentration of ethanol; \(\Delta E\) – is the change of the potential; \(F = 96485.333\) C/mol – is the Faraday constant; \(n = 1\) – is the number of electrons in the electrode reaction; \(R = 8.314\) J/(mol × K) – is the universal gas constant; \(T = 298\) K; \(K_{dil}\) – is the coefficient of dilution.

The linearity was proven in the range of ascorbic acid concentrations from 0.039 to 0.31 mmol/L. Calibration curves of the potential change dependence on the ascorbic acid concentrations from 0.039 to 0.31 mmol/L. Calibration curves of the potential change dependence on the concentration of ascorbic acid were plotted (Fig. 2). The regression equations and \(R^2\) for 50% ethanol solution of ascorbic acid; \(y = 284.07x + 23.718\), \(R^2 = 0.9972\); for 60% ethanol solution of ascorbic acid; \(y = 265.25x + 23.718\), \(R^2 = 0.9964\); for 80% ethanol solution of ascorbic acid; \(y = 7.6x + 26.08\), \(R^2 = 0.9958\); for 96% ethanol solution of ascorbic acid; \(y = 189.04x + 25.148\), \(R^2 = 0.9985\); for the water solution of ascorbic acid; \(y = 5.395x + 26.745\), \(R^2 = 0.9971\); for the 20% ethanol solution of ascorbic acid; \(y = 4.49x + 26.13\), \(R^2 = 0.9995\); for the 40% ethanol solution of ascorbic acid; \(y = 284.07x + 24.111\), \(R^2 = 0.9972\); for the 60% ethanol solution of ascorbic acid; \(y = 265.25x + 23.718\), \(R^2 = 0.9964\);

Fig. 2. Calibration curves of \(\Delta E\) vs concentration of the ascorbic acid solutions.

Conclusions

It has been found that the concentration of ethyl alcohol affects the change of the potential in the electrochemical cell and the level of AOA of ascorbic acid solutions. The percentage of the contribution of ethyl alcohol to the AOA value ranges from 1.85 to 7.63%.

The approach and the formula for calculation that take into account the effect of ethyl alcohol on the final AOA result of the test sample in a water-alcohol solutions have been proposed.

The results of this study can be used in the pharmaceutical and food industries to determine, assess and control the AOA level of dietary supplements, liquid extracts, tinctures, medicines, and alcoholic beverages.
