Introduction
Inhibitor of differentiation/DNA binding (Id) proteins belong to a subfamily of helix–loop–helix (HLH) proteins. Four mammalian members of this family (Id1–Id4) have been identified. The distinguishing characteristic of Id proteins is that, unlike the basic HLH proteins, they do not contain a basic DNA binding domain. Nevertheless, they can regulate cell functions primarily by dimerization with other transcriptional regulators, principally basic HLH proteins.

There is extensive documentation that Id proteins promote cell proliferation and negatively regulate differentiation. High levels of Id gene expression have also been observed in tumor cell lines derived from different tissues [1,2]. In accordance with this, one of the members of this gene family (Id-1) has been shown to promote proliferation and to inhibit functional differentiation of mouse mammary epithelial cells (SCp2 cells), maintained in cell culture [3].

The normal mammary gland is composed of several cell types, but it is the luminal epithelial cells lining the inside of the ducts and the lobules that are primarily targeted for proliferation, differentiation and carcinogenesis. Therefore, to assess the precise significance of any regulatory factor in mammary biology and its significance to carcinogenesis, it is essential to examine its cellular localization in vivo.

This is particularly important in the case of ubiquitously expressed proteins, such as Ids. Accordingly, in the present study we examined the in situ localization of Id-1.
in normal mammary glands, and we report that Id-1 is not expressed in the luminal epithelial cells.

**Materials and methods**

The source of mammary tissues, FVB and BALB/c strains of mice, used for developmental studies were as follows: pubertal (6 weeks old), adult nulliparous (12 weeks old), early pregnant (6 days gestation), lactating (day 7, post-partum), and postlactational involution (3 days after pup removal). Id-1 null mutant mice (129Sv/C57BL) have been described previously [4]. For these null mutant mice, the corresponding strain of wild type mice was used as a control. The mice were housed and cared for in accordance with the National Institutes of Health guide to humane use of animals in research.

For immunoblot analyses, tissues were frozen in liquid nitrogen and stored at −70°C until use. For immunohistochemical analyses, mammary glands were fixed in 4.7% buffered formalin, dehydrated, embedded in paraffin and cut into 5 µm thick sections. Tissue sections from paraffin-embedded normal human breast were kindly provided by Dr Paul Yaswen.

**Source of anti-Id-1 antibody**

An anti-Id-1 rabbit polyclonal antibody (C-20) and the peptide used for the generation of the antibody were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA).

**Immunoblot analyses**

Protein extracts were prepared from mammary tissues by homogenization in lysis buffer (50 mM Tris–HCl [pH 8.0], 125 mM NaCl, 1 mM sodium fluoride, 1 mM sodium orthovanadate, 10 mM sodium pyrophosphate and 1 mM phenylmethylsulfonyl fluoride) containing the protease inhibitors leupeptin, pepstatin and aprotinin, each at a final concentration of 1 µg/ml. The homogenates were sonicated, centrifuged at 110,000 g, and the pellets were discarded. Protein concentrations in the supernatants (lysates) were determined by DC protein assay (BioRad, Hercules, CA, USA). Aliquots of mammary gland lysates equivalent to 40 µg protein were subjected to electrophoresis through 10–20% gradient gels and transferred to nitrocellulose membranes. The membranes were blocked with 10% nonfat powdered milk prior to treatment with the primary antibody. The blots were subsequently washed and treated with appropriate secondary antibodies. The resulting antigen–antibody complexes were detected by the ECL system (Amersham Pharmacia biotech, Chalfont, UK).

**Analysis for in situ localization of Id-1**

For immunohistochemistry, tissue sections were deparaaffinized, rehydrated, and soaked in antigen unmasking solution (Vector, Burlingame, CA, USA). The sections were then heated in the microwave oven for 21 min to reveal antigens. The sections were incubated with Immuno Pure Peroxidase Suppressor (Pierce, Rockford, IL, USA) to quench the endogenous peroxidase for 1 hour. The Biotin/Avidin blocking kit (Vector) was then used to block the nonspecific background. The antigen–antibody complexes were identified using the Universal DAKO LSAB2-labeled streptavidin–biotin peroxidase kit (DAKO, Carpinteria, CA, USA). The sections were counterstained with Mayer’s hematoxylin solution (DAKO).

**Results**

**Validation of the antibody**

The Id-1 antibody used in the present studies (C-20) was the same as that used previously in immunoblot analyses for demonstrating Id-1 expression in various tissue/cell extracts, including mammary cells [3,5–8]. As shown in Figure 1, in immunoblot analyses of whole mammary gland extracts of wild type mice (lanes 1 and 3 corresponding to 129Sv/C57BL and FVB, respectively), two immunoreactive bands were detected in the region of 15–20 kDa. Among these, the top band was absent in extracts prepared from mammary glands of Id-1 null mutant mice (Fig. 1, lane 2), indicating that it corresponded to Id-1. In contrast, in extracts of wild type mouse testis, as reported previously [5], a single immunoreactive band was detected (Fig. 1, lane 4) and this corresponded to the top band in mammary extracts. Similarly, only the top band was detected in extracts of wild type mouse uterus and intestine (Fig. 1, lanes 5 and 6, respectively). Both the top and the bottom bands, detected in mammary extracts of wild type mice, were absent when blots were incubated with Id-1 antibody in the presence of the peptide used for generation of the antibody (Fig. 1, lane 7). These bands were also absent with the deletion of the primary antibody (data not shown). These observations thus confirmed that the C-20 antibody was capable of detecting Id-1, and also demonstrated its presence in whole mammary gland extracts.

The C-20 antibody is known to detect Id-1 in paraffin-embedded tissue sections and has been used successfully for the analyses of Id-1 in sertoli cells of testis by immunohistochemistry [5]. Nevertheless, we verified the ability of the C-20 antibody to detect Id-1, with fidelity, in immunohistochemical analyses. To achieve this we analyzed the vasculature of the developing brain, since Id-1 gene expression has been demonstrated previously in this tissue, by *in situ* hybridization [9]. Immunoreactivity was detected in the nuclei of the vasculature of the developing brain, as shown in Figure 2A,B, and the pattern of immunostaining was similar to that observed for Id-1 gene expression.

**Id-1 is not detectable in luminal epithelial cells of mammary glands**

We next examined the *in situ* localization of Id-1 in mammary glands. As shown in Figure 3A, immunoreactiv-
Immunoblot analyses for Id-1 in various mouse tissues. Lysates were prepared from various mouse tissues and analyzed for Id-1, using C-20 antibody, as described in the text. The positions of the molecular weight standards (kDa) are shown on the right. Lanes 1 and 3, wild type mammary glands (129Sv/C57BL and FVB, respectively); lane 2, mammary glands from Id-1 null mutant mouse; lanes 4–6, testis, uterus and intestine from wild type mice, respectively; lane 7, mammary gland extract of wild type mice in which treatment with the primary antibody was performed in the presence of the blocking peptide.

Immunohistochemical analyses for Id-1. (A), (B) The immunoreactivity in the vasculature (arrows) of the developing brain (inset, B) at day 12.5 of gestation. Original magnification, (A) 50 x, (B) 400 x.

Immunohistochemical analyses for Id-1 in mammary glands. All tissue sections were treated with the primary antibody (except (B), which was incubated with both the primary antibody and the blocking peptide) and processed as described in the text. (A), (B) Adult nulliparous wild type mice (FVB), (C) normal human mammary gland, (D) adult nulliparous wild type mice (129Sv, C57BL/6) corresponding to the strain of Id-1 null mutant mice, (E) arrows showing the vascular endothelial cells, and (F) vascular endothelial cells (arrows) in an artery (A) and a vein (V) in mammary glands of wild type mice. Original magnification: (A)–(E) 400 x. Insets of (A) and (E), higher magnification (630 x).
In the present report, we have demonstrated that Id-1 is not detectable in the luminal epithelial cells of both mouse and human mammary glands. Our inability to detect Id-1 in these cells is not related to the source of the antibody or techniques since it was possible to detect Id-1 in vascular endothelial cells by immunohistochemistry and via immunoblot analyses of several mouse tissue extracts, including mammary glands. The fact that Id-1 is detected in mammary tissue extracts by immunoblot analyses but not by immunohistochemical analyses therefore indicates that Id-1 detected in whole tissue extracts is derived from non-mammary cells. This argument is supported by our demonstration that Id-1 is expressed in vascular endothelial cells of mammary glands. Furthermore, in contrast to Id-1, we can detect Id-2 in the luminal epithelial cells of mouse mammary glands (N Uehara, Y-C Chou and G Shyamala, unpublished observation) in which Id-2 gene expression has been demonstrated by in situ hybridization [13]. Based on all these observations, we conclude that Id-1 is not expressed in the luminal epithelial cells of mammary glands.

Our studies also demonstrate clearly that in mice, regardless of the strain or the developmental stage, Id-1 is not detectable in the luminal epithelial cells; this included both puberty and early pregnancy, when mammary glands undergo extensive proliferation. Accordingly, our present observations do not support the previous suggestion that, in mammary epithelial cells, Id-1 is a positive and a negative regulator of proliferation and of differentiation, respectively [3]. In turn, the observations also emphasize that the postulated roles for Id-1, using various cell culture models, may not be applicable to all cell types, particularly in vivo [2]. This is exemplified by the fact that much of the information demonstrating various regulatory roles for Id proteins have used fibroblasts and, as shown here, mammary fibroblasts do not express Id-1.

Finally, the detection of ‘non-Id-1’ immunoreactivity in immunoblot analyses and in myoepithelial cells, with immunohistochemistry, requires comment. It is clearly not due to an abundant nonspecific protein since the immunoreactivity associated with the myoepithelial cells is quite discreet. Indeed, the immunoreactivity associated with the myoepithelial cells is completely abolished by the blocking peptide (Fig. 2). It is also not due to Id-2 or Id-3, since this antibody is specific to an epitope in the carboxy terminus of Id-1 and has no crossreactivity with these proteins [6,8]. Furthermore, the nonspecific band detected in immunoblots appears to have some specificity for mammary glands since, to date, we have not detected this band in other mouse tissue extracts. Also, the nonspecific band is eliminated upon exposure to the blocking peptide.

Myoepithelial cells express a number of proteins but several of these are also expressed by luminal epithelial cells [14]. As such, very few proteins are expressed exclusively in the myoepithelial cells, the most prominent one being alpha smooth muscle actin [15]. It is, however, unlikely, that the ‘non-Id-1’ immunoreactivity associated with myoepithelial cells is alpha smooth muscle actin since it has minimal homology to Id-1 and, in particular, to the peptide used for the generation of the antibody. It is therefore most probably due to some other smooth muscle cell-specific protein capable of recognizing the epitope on the Id-1 (C-20) antibody. Identification of this protein can thus lead to establishing another myoepithelial cell-specific marker, which in turn can contribute to our current understanding of the biology of mammary myoepithelial cells.

Conclusion

Id-1 detected in whole mammary gland extracts is not derived from luminal epithelial cells.
