Abstract

By considering the long-wave limit of the regularized long wave (RLW) equation, we study its multiple-time higher-order evolution equations. As a first result, the equations of the Korteweg-de Vries hierarchy are shown to play a crucial role in providing a secularity-free perturbation theory in the specific case of a solitary-wave solution. Then, as a consequence, we show that the related perturbative series can be summed and gives exactly the solitary-wave solution of the RLW equation. Finally, some comments and considerations are made on the N-soliton solution, as well as on the limitations of applicability of the multiple scale method in obtaining uniform perturbative series.

03.40.Kf
I. INTRODUCTION

The regularized long wave (RLW) equation,

\[ u_t + u_x - u_{xxt} - 6uu_x = 0, \]  

also known as Peregrine [1] or Benjamin-Bona-Mahony [2] equation, was originally introduced as an alternative for the Korteweg-de Vries (KdV) equation

\[ u_t + u_x + u_{xxx} - 6uu_x = 0. \]

Despite having quite different dispersion properties, these two equations present some intimate relationship. For example, the linear dispersion relation of the RLW equation is

\[ \omega(k) = \frac{k}{1 + k^2}, \]

which, by the way, is the same as the dispersion relation of the shallow water wave equation [3]. For long waves, \( k \) is small and \( \omega(k) \) can be expanded according to

\[ \omega(k) = k - k^3 + O(k^5). \]

The first two terms of this expansion coincide exactly with the complete linear dispersion relation of the KdV equation. Thus, for sufficiently long waves, the traveling-wave solutions of Eqs. (1) and (2) are expected to be quite similar. Despite of this, there is a deep difference between these two cases since a polynomial is definitely not equivalent to an infinite series. This difference, which appears when higher order terms of the dispersion relation expansion are considered, might also show up at higher order approximations in a perturbation theory.

As is well known, the KdV equation appears as governing the first relevant order of an asymptotic perturbation expansion describing weakly nonlinear dispersive waves. However, to make sense of it as really governing such waves, the large time behaviour of the perturbative series must be analyzed [4]. In other words, one needs to study the evolution equations of the higher order terms of the perturbative expansion to check for the existence or not of
secular producing terms. This study, usually neglected in the derivation of the KdV equation, is essential to guarantee the uniformity of the perturbative expansion, rendering thus a real meaning to the KdV equation.

Motivated by the above considerations, we are going in this paper to apply a multiple time version \([5]\) of the reductive perturbation method to study long waves as governed by the RLW equation. As we are going to see, the KdV equation appears at the lowest relevant order of the perturbative scheme. Then, by assuming a solitary-wave solution for the KdV equation, we consider the higher order approximations and we show that the corresponding solitary-wave related secular producing terms can be eliminated from every order of the perturbative scheme. The equations of the KdV hierarchy, which appear as a consequence of natural compatibility conditions, are shown to play a crucial role in the process of eliminating the secular producing terms. Once a secularity-free perturbative series is obtained, we show that it may be summed to give the exact solitary-wave solution of the RLW equation. We then close the paper with a discussion on the N-soliton case, as well as on the limitations of the multiple scale method.

\[ II. \text{MULTIPLE-TIME FORMALISM} \]

To study the long-wave limit of the RLW equation we put

\[ k = \epsilon \kappa, \]  

with \( \epsilon \) a small parameter. In this limit, the dispersion relation \((3)\) can be expanded as

\[ \omega(\kappa) = \epsilon \kappa - \epsilon^3 \kappa^3 + \epsilon^5 \kappa^5 - \epsilon^7 \kappa^7 + \cdots. \]  

Accordingly, the solution of the corresponding linear RLW equation can be written in the form

\[ u = a \exp i[kx - \omega(k)t] \equiv a \exp i \left[ \kappa \epsilon (x - t) + \epsilon^3 \kappa^3 t - \epsilon^5 \kappa^5 t + \epsilon^7 \kappa^7 t + \cdots \right], \]  

where \( a \) is a constant. As given by this solution, we define now a slow space
\[ \xi = \epsilon (x - t), \quad (8) \]

as well as an infinity of properly normalized slow time variables:
\[ \tau_3 = \epsilon^3 t \; ; \; \tau_5 = -\epsilon^5 t \; ; \; \tau_7 = \epsilon^7 t \; ; \; \text{etc.} \quad (9) \]

Consequently, we have
\[ \frac{\partial}{\partial x} = \epsilon \frac{\partial}{\partial \xi}, \quad (10) \]

and
\[ \frac{\partial}{\partial t} = -\epsilon \frac{\partial}{\partial \xi} + \epsilon^3 \frac{\partial}{\partial \tau_3} - \epsilon^5 \frac{\partial}{\partial \tau_5} + \epsilon^7 \frac{\partial}{\partial \tau_7} - \cdots . \quad (11) \]

It is important to notice that the introduction of slow time variables normalized according to the dispersion relation expansion are such that they allow for an automatic elimination of the solitary-wave related secular–producing terms appearing in the evolution equations for the higher order terms of the wave–field \([6]\).

**III. PERTURBATION THEORY**

The perturbative scheme consists of making the expansion
\[ u \equiv \epsilon^2 \hat{u} = \epsilon^2 (u_0 + \epsilon^2 u_2 + \epsilon^4 u_4 + \cdots), \quad (12) \]

and substituting it, together with Eqs.(10) and (11), into the RLW equation (1). The result is the multiple–time equation
\[ \left( \epsilon^3 \frac{\partial}{\partial \tau_3} - \epsilon^5 \frac{\partial}{\partial \tau_5} + \cdots \right) \hat{u} - \epsilon^2 \frac{\partial^2}{\partial \xi^2} \left( -\epsilon \frac{\partial}{\partial \xi} + \epsilon^3 \frac{\partial}{\partial \tau_3} - \epsilon^5 \frac{\partial}{\partial \tau_5} + \cdots \right) \hat{u} \]
\[ -3 \epsilon^3 \frac{\partial}{\partial \xi} \left( u_0^2 + 2 \epsilon^2 u_0 u_2 + \cdots \right) = 0 . \quad (13) \]

We proceed then to an order-by-order analysis of this equation.

At the lowest order, we obtain
\[ u_{0\tau_3} = F_3 \equiv -u_{0\xi\xi\xi} + 6u_0 u_0 \xi = 0, \quad (14) \]
which is the KdV equation. Introducing an operator $L$, whose action on any component $u_n$ is given by the linearized KdV operator

$$Lu_n \equiv u_n \tau_3 + u_n \xi \xi - 6(u_0 u_n) \xi ,$$
(15)

the KdV equation (14) can be rewritten in the form

$$Lu_0 = -6u_0 u_0 \xi .$$
(16)

Our interest in this paper is concerned to solitary-waves. Thus we assume $u_0$ to be the solitary-wave solution of the KdV equation (14),

$$u_0 = -2 \kappa^2 \text{sech}^2 \theta_3 ,$$
(17)

where $\theta_3 = \kappa[\xi - 4\kappa^2 \tau_3]$. In this case, Eq.(16) becomes

$$Lu_0 = 48 \kappa^5 \text{sech}^4 \theta_3 \tanh \theta_3 .$$
(18)

In the next order, we obtain the equation

$$Lu_2 = u_{0 \tau_3 \xi \xi} + u_{0 \tau_5} .$$
(19)

The evolution of $u_0$ in the time $\tau_3$ is given by the KdV equation (14), but the evolution of $u_0$ in the time $\tau_5$ is not known up to this point. However, the multiple–time formalism introduces constraints which determine uniquely the evolution of $u_0$ in any higher–order time [5]. To see how this is possible, let us make the following considerations.

First, to have a well ordered perturbative scheme, we impose that each one of the equations describing the higher-order times evolution of $u_0$ be $\epsilon$-independent when passing from the slow ($\kappa, u_0, \xi, \tau_{2n+1}$) to the laboratory coordinates ($k, u, x, t$). This will select all possible terms to appear in $u_{0 \tau_{2n+1}}$. For instance, the evolution of $u_0$ in the time $\tau_5$ is restricted to be of the form

$$u_{0 \tau_5} = \alpha_5 u_0(\xi) + \beta_5 u_0 u_0 \xi \xi + \gamma_5 u_0 \xi u_0 \xi + \delta_5 u_0^2 u_0 \xi ,$$
(20)
where $\alpha_5$, $\beta_5$, $\gamma_5$ and $\delta_5$ are constants to be determined. Then, by imposing the natural (in
the multiple time formalism) compatibility condition

$$
\left( u_{\tau_3} \right)_{\tau_5} = \left( u_{\tau_5} \right)_{\tau_3},
$$

it is possible to determine the above constants in terms of $\alpha_5$, which is left as a free-
parameter. As it can be verified [3], the resulting equation is the 5th order equation of the
KdV hierarchy:

$$
u_{\tau_5} = F_5 \equiv u_{0(5\xi)} - 10u_0u_{0\xi\xi\xi} - 20u_{0\xi}u_{0\xi\xi} + 30u_0^2u_{0\xi}.
$$

The right-hand side of this equation would in principle appear multiplied by the free param-
eter $\alpha_5$, which would account for different possible normalizations of the time $\tau_5$. However,
since we have already defined the slow time normalizations, this parameter was taken to be
1 in order to have an agreement with the normalizations introduced in Eq.(19). This is an
important point since, as we have already said, it allows for an automatic elimination of the
solitary-wave related secular producing terms appearing in the right–hand side of Eq.(19).
These terms, when $u_0$ is assumed to be a solitary–wave of the KdV equation, are always of
the form [7]

$$
u_0(2n+1)\xi; \quad n = 0, 1, 2, \ldots.
$$

Thus, using Eqs.(14) and (22) to describe respectively $u_{\tau_3}$ and $u_{\tau_5}$, Eq.(19) becomes

$$
Lu_2 = -2u_{0\xi}u_{0\xi} - 4u_0u_{0\xi\xi\xi} + 30u_0^2u_{0\xi}.
$$

We notice in passing that the substitution of Eqs.(14) and (22), respectively for $u_{\tau_3}$ and
$u_{\tau_5}$, with the properly normalized slow times allowed for an automatic elimination of all
solitary-wave related secular producing terms of Eq.(19). In fact, Eq.(24) does not present
any secular-producing term anymore. Moreover, we see that at this order $u_0$ must satisfy
simultaneously the first two equations of the KdV hierarchy, respectively in the slow-times
$\tau_3$ and $\tau_5$. Introducing the general definition
\[ \theta_{2n+1} = \kappa \left[ \xi - 4\kappa^2 \tau_3 + 16\kappa^4 \tau_5 + \cdots + (-1)^n (2\kappa)^{2n} \tau_{2n+1} \right], \tag{25} \]

such a solitary-wave is given by
\[ u_0 = -2\kappa^2 \text{sech}^2 \theta_5, \tag{26} \]

and Eq.(24) becomes
\[ Lu_2 = 192\kappa^7 \text{sech}^4 \theta_5 \tanh \theta_5. \tag{27} \]

Assuming a vanishing solution for the associated homogeneous equation, we can write the solution of this equation in the form
\[ u_2 = 4\kappa^2 u_0, \tag{28} \]

with \( u_0 \) given by (26).

We proceed then to the next order, where we get
\[ Lu_4 = -u_{0\tau_7} - u_{0\tau_5 \xi \xi} + u_{2\tau_5} + u_{2\tau_3 \xi \xi} + 6u_2 u_{2\xi}. \tag{29} \]

Following the same scheme used before, we can use the compatibility condition
\[ (u_{0\tau_3})_{\tau_7} = (u_{0\tau_7})_{\tau_3} \tag{30} \]

to obtain the evolution of \( u_0 \) in the time \( \tau_7 \). It is given by
\[ u_{0\tau_7} = F_7 \equiv - u_{0(7\xi)} + 14u_0 u_{0(5\xi)} + 42u_{0\xi} u_{0(4\xi)} + 140(v_0)^3 v_{0\xi} \]
\[ + 70u_{0\xi \xi} u_{0\xi \xi} - 280u_0 u_{0\xi} u_{0\xi \xi} - 70(u_{0\xi})^3 - 70u_0^2 u_{0\xi \xi \xi}, \tag{31} \]

which is exactly the 7th order equation of the KdV hierarchy. At this order, therefore, the solitary-wave must satisfy simultaneously the first three equations of the KdV hierarchy, respectively in the times \( \tau_3, \tau_5 \) and \( \tau_7 \). This means that
\[ u_0 = -2\kappa^2 \text{sech}^2 \theta_7. \tag{32} \]
Now, by using Eq.(28) to express $u_2$, and the equations of the KdV hierarchy to express $u_{0_{77}}$, $u_{0_{35}}$ and $u_{0_{33}}$, all secular producing terms of Eq.(29) are automatically eliminated. Then, substituting the solution (32), Eq.(29) becomes

$$L u_4 = 768 \kappa^9 \text{sech}^4 \theta_7 \tanh \theta_7. \quad (33)$$

Again, by assuming a vanishing solution for the associated homogeneous equation, the solution of this equation can be written as

$$u_4 = (4 \kappa^2)^2 u_0, \quad (34)$$

with $u_0$ given now by Eq.(32).

This procedure can be repeated up to any higher order. In other words, we can use the compatibility condition

$$\left( u_{0_{77}} \right)_{\tau_{2n+1}} = \left( u_{0_{77}} \right)_{\tau_3} \quad (35)$$

to obtain the evolution of $u_0$ in the time $\tau_{2n+1}$, which will turn out to be the $(2n + 1)th$ equation of the KdV hierarchy. In this case, $u_0$ will represent a solitary-wave satisfying simultaneously the first $n$ equations of the KdV hierarchy:

$$u_0 = -2 \kappa^2 \text{sech}^2 \theta_{2n+1}. \quad (36)$$

The resulting secularity-free evolution equation at this order will be

$$L u_{2n} = 3 (4)^{n+2} (\kappa)^{2n+5} \text{sech}^4 \theta_{2n+3} \tanh \theta_{2n+3}. \quad (37)$$

Assuming a vanishing solution for the associated homogeneous equation, the solution to this equation can be written in the form

$$u_{2n} = (4 \kappa^2)^n u_0, \quad (38)$$

with $u_0$ given by Eq.(30). Extending this procedure ad infinitum, $u_0$ will represent a solitary-wave satisfying simultaneously all equations of the KdV hierarchy, and we obtain an exact solution for the RLW equation.
IV. RETURNING TO THE LABORATORY COORDINATES

Let us take the solutions $u_{2n}$ and substitute them in the expansion \((12)\). Putting $u_0$ in evidence, we get

$$u = \epsilon^2 u_0 \left[ 1 + 4\epsilon^2 \kappa^2 + 16\epsilon^4 \kappa^4 + 64\epsilon^6 \kappa^6 + \cdots \right]. \quad (39)$$

Now, the above series can be summed:

$$1 + 4\epsilon^2 \kappa^2 + 16\epsilon^4 \kappa^4 + 64\epsilon^6 \kappa^6 + \cdots = \frac{1}{1 - 4\epsilon^2 \kappa^2}. \quad (40)$$

Therefore, we get the RLW exact solution

$$u = -2\epsilon^2 \kappa^2 \frac{1}{1 - 4\epsilon^2 \kappa^2} \text{sech}^2 \left[ \kappa\xi - 4\kappa^3 \tau_3 + 16\kappa^5 \tau_5 - 64\kappa^7 \tau_7 + \cdots \right]. \quad (41)$$

Then, by using Eqs.\((3), (8)\) and \((3)\), we can rewrite $u$ in terms of the laboratory coordinates \((k, x, t)\). The result is

$$u = -\frac{2k^2}{1 - 4k^2} \text{sech}^2 \left[ k(x - t \left(1 + 4k^2 + 16k^4 + 64k^6 + \cdots \right)) \right]. \quad (42)$$

Using again Eq.\((10)\) with $\epsilon\kappa = k$, we get finally

$$u = -a \text{sech}^2 \left[ k \left( x - \frac{t}{1 - 4k^2} \right) \right] ; \quad a = \frac{2k^2}{1 - 4k^2}, \quad (43)$$

which is the solitary-wave solution of the RLW equation \((1)\).

The RLW equation has another solution, given by

$$u = b \tanh^2 \left[ k \left( x - \frac{t}{1 + 8k^2} \right) \right] ; \quad b = \frac{2k^2}{1 + 8k^2}. \quad (44)$$

In fact, it is easy to see that Eq.\((1)\) is invariant under the transformation

$$t' = a^{-1}t \quad ; \quad x' = x \quad ; \quad u' = b - au, \quad (45)$$

where, if $u$ is given by Eq.\((43)\), $u'$ turns out to be the solution given by Eq.\((44)\). By following

the same procedure used to obtain the RLW solitary-wave solution \((43)\), it is also possible
to use the multiple-time perturbative scheme to obtain the solution (44). This is done by choosing
\[ u_0 = 2\kappa^2 \tanh^2 \left( \kappa \xi - 8 \kappa^3 \tau_3 \right) , \] instead of (17) as the solution for the KdV equation (14). As higher orders are reached, this \( u_0 \) is required to satisfy also the higher order equations of the KdV hierarchy, which amounts to include dependences on the higher order times \( \tau_5, \tau_7, \) etc. However, there is an important difference: the secular-producing term in each order of the perturbative scheme will come not only from the linear term, but from both the linear and the nonlinear terms. As a consequence, the slow time normalizations obtained from the linear dispersion relation expansion will not be able to remove the secular-producing terms in this case. In other words, new slow time normalizations will be needed to get a secularity-free perturbative series. These new normalizations can be easily found by properly choosing the free-parameters left at each order of the perturbation scheme \[6\]. After doing that, we obtain the following perturbative series for \( u \):
\[ u = \varepsilon^2 \left[ 1 - 8\kappa^2 + 64\kappa^4 - \cdots \right] \tanh^2 \left[ kx - k \left( 1 - 8\kappa^2 + 64\kappa^4 - \cdots \right) \right] . \] Like in the previous case, these series can be summed, resulting in
\[ u = \frac{2\kappa^2}{1 + 8\kappa^2} \tanh^2 \left[ k \left( x - \frac{t}{1 + 8\kappa^2} \right) \right] , \] which is the solution (44) of the RLW equation. As already said, however, a new slow time normalization is needed in this case to get a secularity-free perturbative series, which is different from that obtained from the dispersion relation expansion.

**V. STUDY ON THE APPLICABILITY OF THE MULTIPLE SCALE METHOD**

The multiple scale method is not always able to remove all the secular-producing terms of a perturbative series \[5\]. In some cases, nonintegrable effects may preclude the existence of uniform asymptotic expansions. Considering that the RLW is nonintegrable, the purpose of
this section will be to make a brief discussion on how those effects appear in the higher order terms of the perturbative series for the specific case of the RLW equation. The approach we are going to use is that developed by Kodama and Mikhailov \[8\].

Let us start by defining slow variables according to

\[ u = \epsilon v ; \quad \xi = \epsilon^{1/2}(x - t) ; \quad \tau_3 = \epsilon^{3/2}t . \] (49)

In these new coordinates, and up to terms of order \( \epsilon^2 \), Eq. (1) becomes

\[ v_{\tau_3} = \partial_\xi \left[ 3v^2 - v_{\xi\xi} + \epsilon \partial_\xi \left( 3v^2 - v_{\xi\xi} \right) + \epsilon^3 \partial_{(4\xi)} \left( 3v^2 - v_{\xi\xi} \right) + \cdots \right] . \] (50)

Then, we make a near identity transformation \[9\] given by

\[ v = w + \epsilon \Phi(w) + \epsilon^2 \Psi(w) + O(\epsilon^3) , \] (51)

where, by reasons of scaling-weight invariance, the differential polynomials \( \Phi \) and \( \Psi \), which are allowed to be nonlocal, can involve only the following terms:

\[ \Phi = \alpha w^2 + \beta w\xi\xi + \gamma w\xi\partial^{-1}w , \] (52)

\[ \Psi = aw^3 + b(w\xi)^2 + cw\xi\xi + dw_{(4\xi)} + ew\xi\partial^{-1}w + f w\xi\partial^{-1}(w^2) + g w\xi\xi\xi\partial^{-1}w + hw\xi\xi\xi\partial^{-1}(w^2) . \] (53)

Substituting into (50), we obtain

\[ w_{\tau_3} = K_3 + \epsilon K_5 + \epsilon^2 K_7 + \cdots , \] (54)

with

\[ K_3 = \partial_\xi M_0 , \] (55)

\[ K_5 = \partial_\xi \left( M_1 + \partial_\xi M_0 \right) - \frac{\delta \Phi}{\delta w} (\partial_\xi M_0) , \] (56)

\[ K_7 = \partial_\xi \left( M_2 + \partial_\xi M_1 + \partial_{(4\xi)} M_0 \right) - \frac{\delta \Psi}{\delta w} (\partial_\xi M_0) \]

\[ - \frac{\delta \Phi}{\delta w} \left[ \partial_\xi \left( M_1 + \partial_\xi M_0 \right) - \frac{\delta \Phi}{\delta w} (\partial_\xi M_0) \right] , \] (57)
where we have introduced the notation:

\[ M_0 = 3w^2 - w_{\xi\xi}, \quad \text{(58)} \]

\[ M_1 = 6w\Phi - \Phi_{\xi\xi}, \quad \text{(59)} \]

\[ M_2 = 3\Phi^2 + 6w\Psi - \Psi_{\xi\xi}. \quad \text{(60)} \]

At order \( \epsilon^0 \) we find

\[ K_3 = F_3 \equiv 6ww_\xi - w_{\xi\xi\xi}, \quad \text{(61)} \]

that is, \( K_3 \) is the symmetry of order \( \epsilon^0 \) of the KdV equation. At the next order, by properly choosing \( \alpha, \beta \) and \( \gamma \), we find

\[ K_5 = F_5, \quad \text{(62)} \]

with \( F_5 \) defined by Eq.(kdv5). This means that there exists a near-identity transformation (51)-(53) such that \( K_5 \) is the symmetry of order \( \epsilon \) of the KdV equation. In the first two orders, therefore, no problems appear. This is a general result that holds for any equation, not only for the particular case of the RLW equation. It is in the next order that the so-called obstacles [8] show up. In fact, in the next order we get

\[ K_7 = F_7 + O(w), \quad \text{(63)} \]

with \( F_7 \) defined by Eq.(31), and \( O(w) \) representing the obstacle, which is given by

\[
O(w) = \left( -\frac{32}{3} - 3g \right) w w_{(5\xi)} + \left( -\frac{20}{3} - 3c - 24d - 3g \right) w_\xi w_{(4\xi)} \\
+ \left( -\frac{508}{3} + 6a + 2f - 18g \right) w^3 w_\xi + (22 - 3c - 6b - 60d) w_\xi w_{\xi\xi\xi} \\
+ \left( \frac{700}{3} - 18a - 12c - 6f + 72g \right) w w_\xi w_\xi + \left( \frac{224}{3} - 3f + 21g \right) w^2 w_{\xi\xi\xi} \\
+ \left( \frac{158}{3} - 6a - 6b - 3f + 18g \right) (w_\xi)^3. \quad \text{(64)}
\]
The important point is that, for an arbitrary KdV hierarchy solution $w$, it is not possible to choose $a, b, \ldots, g$ in such a way to have a vanishing obstacle. However, as an explicit calculation easily shows, when $w$ is a solitary-wave solution of the KdV hierarchy, there is a near-identity transformation leading to $O(w) = 0$.

The above considerations are important in the sense that they clarify the results obtained in the previous sections concerning the solitary-wave related secularities. But, at the same time, they put in evidence the limitations of the perturbative scheme which, as we now know, can not be extended to the two-or-more soliton solutions in the non-integrable case. On the other hand, for integrable systems, like for example the shallow water wave equation, the multiple scale method will be able to handle both, the solitary-wave and the N-soliton related secularities since no obstacles will be present in either case.

VI. FINAL REMARKS

We have applied a multiple-time version of the reductive perturbation method to study the solitary-wave solution of the RLW equation. As it has already been shown, the use of multiple time-scales allows for the elimination of all solitary-wave related secular-producing terms appearing in the evolution equations of the higher-order terms of the wave-field. Moreover, it has also been shown that these secularities are automatically removed if the slow time-scales are normalized according to the long-wave expansion of the dispersion relation of the original equation. By using this strategy, we have succeeded in expressing the solitary-wave solution of the RLW equation as a sum of solitary-waves satisfying simultaneously, in the slow coordinates, all equations of the KdV hierarchy. Similar results have been shown to hold also for the Boussinesq and the shallow water wave equations. However, while in these two cases the solitary-wave solution was obtained due to a truncation of the perturbative series, the RLW solitary-wave was obtained by summing the perturbative series.

To finish, let us make the following considerations. If we assume the RLW equation
to be an exact model equation, as we have in fact done, the KdV equation appears as its long wave leading order approximation. This is one more confirmation of the widely known property of the KdV equation, which states that it holds a unique, privileged and universal meaning in the sense it appears as the leading order approximation of any weakly nonlinear dispersive systems, as for example that represented by the RLW equation. From this point of view, the old dispute [12] on the equivalence of the RLW and the KdV equations would be made on a different ground since the RLW equation should be compared not to the KdV equation, but to the whole set of equations of the KdV hierarchy. In other words, the RLW equation should be compared not to its leading order approximation, but to the whole perturbative series. And according to our results, as far as solitary-waves are concerned, the RLW equation is indeed equivalent to the KdV hierarchy since a solitary-wave of the RLW equation is nothing but an infinite series given by the sum of solitary-waves satisfying simultaneously all equations of the KdV hierarchy, each one in a different slow time variable.

ACKNOWLEDGEMENTS

The authors would like to thank J. Léon for useful discussions. They would also like to thank Y. Kodama and A. V. Mikhailov for sending the preprint of reference [8] to them. This work has been partially supported by CNPq (Brazil) and CNRS (France).
