Coupled Control Systems: Periodic Orbit Generation with Application to Quadrupedal Locomotion

Wen-Loong Ma, Noel Csomay-Shanklin and Aaron D. Ames

Abstract—A robotic system can be viewed as a collection of lower-dimensional systems that are coupled via reaction forces (Lagrange multipliers) enforcing holonomic constraints. Inspired by this viewpoint, this paper presents a novel formulation for nonlinear control systems that are subject to coupling constraints via virtual “coupling” inputs that abstractly play the role of Lagrange multipliers. The main contribution of this paper is a process—mirroring solving for Lagrange multipliers in robotic systems—wherein we isolate subsystems free of coupling constraints that provably encode the full-order dynamics of the coupled control system from which it was derived. This dimension reduction is leveraged in the formulation of a nonlinear optimization problem for the isolated subsystem that yields periodic orbits for the full-order coupled system. We consider the application of these ideas to robotic systems, which can be decomposed into subsystems. Specifically, we view a quadruped as a coupled control system consisting of two bipedal robots, wherein applying the framework developed allows for gaits (periodic orbits) to be generated for the individual biped yielding a gait for the full-order quadruped. This is demonstrated through walking experiments of a quadruped robot in simulation and on rough terrains.

I. INTRODUCTION

To achieve dynamic walking on high-dimensional robotic systems, hybrid zero dynamics (HZD) has proven to be a successful methodology as a result of its ability to make theoretic guarantees [19], [7], [2] and yield walking for complex humanoids [17], [14]. The main idea behind this approach is that the full-order dynamics of the robot can be reduced to a lower-dimensional surface on which the system evolves. The system can then be studied via the low-dimensional dynamic representation and, importantly, guarantees made can be translated back to the full-order dynamics, i.e., periodic orbits (or walking gaits) in the low-dimensional system imply corresponding periodic orbits in the full-system. The goal of this paper is to capture this dimension reduction in a more general context—that of coupled control systems, which capture the ability to decompose a complex system into low-dimensional subsystems.

Another means of dimension reduction for robotic systems comes from isolating subsystems and coupling these subsystems at the level of reaction forces, i.e., Lagrange multipliers that enforce holonomic constraints. This is the idea underlying the highly efficient method for calculating the dynamics of robotic systems: Spatial vector algebra [5]. For example, a double pendulum can be decomposed into two single pendula connected via a constraint at the pivot joint [6]. More generally, one can consider two equivalent ways of expressing the dynamics of a robotic system [13]:

\[ D(q)\ddot{q} + H(q, \dot{q}) = u \Leftrightarrow \begin{cases} D_i(q)\ddot{q}_i + H_i(q_i, \dot{q}_i) = u_i + J_{hi}^\top \lambda \\ \text{s.t.} \quad h(q) = 0 \end{cases} \]

for \( i = 1, 2 \), where \( h \) is a coupling (holonomic) constraint that is enforced via the Lagrange multiplier \( \lambda \) allowing for the higher-dimensional \( q \) to be decomposed into lower-dimensional \( q_i \), i.e., \( q = (q_1, q_2) \). For example, a quadruped robot can be decomposed into two bipeds as in Fig. 1. Thus, if one can make guarantees on the reduced-order coupled systems, they can be translated to the full-order dynamics.

The study of coupled dynamic and control systems has a long and rich history from which the framework presented in this paper has taken inspiration. The most prevalent example is that of multi-robot systems [12], and specifically the consensus problem [15]. Interconnected systems have also been well-studied [3]. In the context of mechanical and robotic systems on graphs, network synchronization has been considered [4]. Port-Hamiltonian systems also capture the notion of coupling present in general mechanical systems [18]. Finally, in related work, the coordination of quadruped and human reaction forces has recently been studied [8]. While not explicitly discussed due to space constraints, many of these formulations fit within the general setting of coupled control systems presented here.

This paper generalizes the aforementioned methods — zero dynamics and system decomposition through coupling constraints — and unifies them through a novel formulation: coupled control systems. We then utilize zero dynamics to reduce to a subsystem dependent on coupling constraint which is then eliminated via coupling relations to yield the final isolated subsystem. The main result of this paper is that
solutions of the isolated system are solutions of the full-order system, and thus periodic orbits on the subsystem yield periodic orbits on the full-order system. This result is leveraged to construct a nonlinear optimization problem utilizing collocation methods to generate these periodic solutions.

Our motivating application is gait (periodic orbit) generation for quadrupedal robots. Previously, HZD methods were applied to quadrupedal walking [10]; yet the high dimensionality of this system made it computationally expensive to generate gaits when compared to their bipedal analogs. To address this shortcoming, recent work has aimed at decomposing quadruped into bipedal robots [11]—it is this methodology that this paper formalizes and extends. Therefore, we consider a quadrupedal robot utilizing the coupled control system paradigm, wherein this system can be reduced to lower-dimensional subsystems on which periodic orbits (gaits) can be generated. We demonstrate the results through the realization of these generated gaits experimentally to achieve stable walking on rough terrains.

II. Coupled Control Systems

This section introduces the notion of coupled control systems, for which a collection of differential equations are coupled via algebraic coupling condition. The goal is to characterize such systems where feedback control laws: $\bar{c}(x,z) \equiv -c_e(z_j, z_i) \equiv 0$ are given by a set of DAEs:

$$\begin{align*}
\dot{x}_i &= f_i(x_i, z_i, u_i) + g_i(x_i, z_i)u_i + \bar{g}_i(x_i, z_i, z_j)\lambda_e \\
\dot{z}_i &= p_i(x_i, z_i, u_i) + \bar{q}_i(x_i, z_i, z_j)\lambda_e \\
\text{s.t.} \quad c_e(z_j, z_i) &= z_i - z_j = -c_e(z_j, z_i) \equiv 0 \\
\lambda_e &= -\lambda_r
\end{align*}$$

where, $x_i \in \mathcal{X}_i, z_i \in \mathcal{Z}_i, u_i \in \mathcal{U}_i$, and $c_e(z_j, z_i) \equiv 0$ is a \textit{coupling constraint} enforced by the \textit{coupling inputs} $\lambda_e$, which $\equiv$ represents the identical equality of functions.

We additionally denote $x = \{x_1, x_2\} \in \mathcal{X}, z = \{z_1, z_2\} \in \mathcal{Z}, u = \{u_1, u_2\}$ throughout the paper.

\textbf{Solutions.} We define solutions of coupled control systems by assuming the existence of feedback control laws: $u_i(x, z) \equiv \{u_1(x_1, z), u_2(x_2, z)\}$. Applying these controllers to (1) yields a coupled dynamical system (CDS):

$$\begin{align*}
\mathcal{D}_C \triangleq \begin{cases}
\dot{x}_i &= f_i^C(x_i, z_i) + g_i(x_i, z_i)u_i + \bar{g}_i(x_i, z_i, z_j)\lambda_e \\
\dot{z}_i &= p_i^C(x_i, z_i) + \bar{q}_i(x_i, z_i, z_j)\lambda_e \\
\text{s.t.} \quad c_e(z_i, z_j) &= 0, \quad \lambda_e = -\lambda_r
\end{cases}
\end{align*}$$

where, $f_i^C \triangleq f_i(x_i, z_i, z_j) + g_i(x_i, z_i)u_i + \bar{g}_i(x_i, z_i, z_j)\lambda_e$, and $p_i^C \triangleq p_i(x_i, z_i) + q_i(x_i, z_i, z_j)u_i + \bar{q}_i(x_i, z_i, z_j)\lambda_e$.

Then the \textbf{solution} of the coupled dynamic system, $\mathcal{D}_C$, is a set of solutions:

$$\{ (x_1(t), z_1(t), \lambda_e(t)), (x_2(t), z_2(t), \lambda_e(t)) \}$$

subject to \textit{with initial condition:} $\{ (x_1(0), z_1(0), \lambda_e(0)), (x_2(0), z_2(0), \lambda_e(0)) \}$, and $I \subset \mathbb{R}$ is the time interval of their existence. Per the above notation, we will sometimes denote the solutions by $(x(t), z(t), \lambda(t))$ with initial condition $(x(0), z(0), \lambda(0))$.

\textbf{Coupling constraints.} Importantly, the solutions must satisfy the coupling constraints at all time. Therefore,

$$c_e(z) \equiv 0 \Rightarrow \dot{c}_e(z, \dot{z}) \equiv 0$$

$$\begin{align*}
\dot{c}_e(z, \dot{z}) &= \frac{\partial c_e(z_i, z_j)}{\partial z_i} \dot{z}_i + \frac{\partial c_e(z_i, z_j)}{\partial z_j} \dot{z}_j \\
&= \frac{\partial J_c^{(i,j)}(z)}{\partial z_i} \dot{z}_i + \frac{\partial J_c^{(i,j)}(z)}{\partial z_j} \dot{z}_j \equiv 0
\end{align*}$$

Hence, to solve for the coupling inputs $\lambda_e$ that satisfy the coupling constraints, it is necessary to solve an equation that depends on the states of both subsystems. To address this, we present a method for isolating a subsystem via conditions on the controllers of the other systems in the next section. Before doing this, we utilize the following example to illustrate the concepts of coupled control systems.

\textbf{Application to quadrupedal robots.} The motivating application considered here, is to compute periodic solutions of the quadrupedal dynamics. As Fig. 2 shown, we decompose this quadruped into two bipeds, whose dynamics are on a CCS graph (according to definition 1): $\Gamma \triangleq (N = \{f, r\}, E = \{(e, f), (e, r)\})$, where $f, r$ label the \textit{front} and \textit{rear} bipedal systems, correspondingly. We picked the coordinates for these two subsystems as $q_i = (\xi_{i,1}, \theta_{i,1}, \theta_{i,2})^T$ for $\xi_i \in \mathbb{R}^3 \times SO(3)$ and the leg joints $\theta_{i,j} \in \mathbb{R}^3$. Since all leg joints are actuated, the inputs are $u_i \in \mathcal{U} \subset \mathbb{R}^6$. The decomposed dynamics of a quadruped as two coupled bipeds in the \textit{continuous phase} are given by a set of DAEs:

$$\begin{align*}
RQ_0 \triangleq \begin{cases}
D_i\dot{q}_i + H_i = J_i^T F_i + B_i u_i + J_i^T \lambda_e & \text{s.t.} \quad c_e(\xi_i, \lambda_i) = \xi_i - \xi_j \equiv 0 \\
J_i\dot{q}_i + J_i\lambda_i = 0
\end{cases}
\end{align*}$$

$$\begin{align*}
\text{s.t.} \quad c_e(\xi_i, \lambda_i) &= \xi_i - \xi_j \equiv 0 \\
\lambda_e &= -\lambda_r
\end{align*}$$

with $D_i(q_i) \in \mathbb{R}^{n \times n}$ the mass-inertia matrix, $H_i(q_i, \dot{q}_i) \in \mathbb{R}^n$ the drift vector, and the actuation matrix $B_i = \begin{bmatrix} 0_{6 \times 6} & I_{6 \times 6} \end{bmatrix}$. The contact (holonomic) constraint $H_i(q_i) \equiv 0$ is enforced via ground reaction forces $F_i \in \mathbb{R}^3$, whose

\textsuperscript{1}The definition for continuous and discrete dynamics (impact dynamics) for hybrid control systems can be found in [7], which is less relevant to the main theme here, hence omitted.
The zero dynamics manifold of a subsystem evolves according to its own dynamics and the zero dynamics of all remaining systems—all of which are coupled via the coupling inputs \( \lambda \).

### B. Explicit Coupling Conditions

The coupling between the control systems (1) is enforced via \( \lambda \) and the coupling constraints of the form (4), similarly, even in the reduction to a subsystem (12), the coupling is still achieved through \( \lambda \). We wish to generalize this so as to remove the coupling, i.e., isolate subsystems, while still preserving the overall behavior of the full system. We first define the **coupling relation** that allows the use of the controllers \( u_j^{Z,\lambda} \) to eliminate the dependence on the controllers and internal states of the other subsystem.

**Definition 2.** For a \( \lambda \)-CCSub \( C_j^{Z,\lambda} \) and \( i \in \mathbb{N} \), a **coupling relation** is a functional relationship on the coupling inputs \( \lambda^e(x_i, z; u_i) = A^e(x_i, z) u_i + b^e(x_i, z) \), (13) that satisfies the coupling constraint (5) for all \( e = (i, j) \in \mathbb{E} \).

The coupling relation is then summarized in the following:

**Lemma 1.** For a \( \lambda \)-CCSub \( C \), if we have

\[
\bar{Q}_e(x_i, z) \triangleq \begin{bmatrix} g_i(0, z) \\ q_i(0, z) \\ \bar{g}_e(0, z) \\ \bar{q}_e(x_i, z) \\ \bar{g}_e(x_i, z) \end{bmatrix} \text{ invertible, there exists a controller } u_j^{Z,\lambda} \text{ that renders } Z_j^{\lambda} \text{ invariant and a coupling relation in (13), given by:}
\]

\[
\begin{bmatrix} u_j^{Z}(0, z; u_i) \\ \lambda^e(x_i, z; u_i) \\ A^e(x_i, z) \end{bmatrix} = \bar{Q}_e^{-1} \begin{bmatrix} 0 \\ q_i(0, z) \\ \bar{g}_e(0, z) \\ -f_j(0, z) \\ -f_i(0, z) \end{bmatrix}
\]

**Proof:** Evaluating (5) along the zero dynamics manifold \( Z_j \), i.e., \( x_i \equiv 0 \), yields: \( q_i(x_i, z) u_i + p_i(x_i, z) - p_j(0, z) = q_j(0, z) u_j^{Z}(0, z; u_i) - \bar{q}_e(x_i, z) + \bar{g}_e(0, z) \lambda_e \). Combining this with (11) and simultaneously solving for \( u_j^{Z,\lambda} \) and \( \lambda^e \) yields the desired result.

Recall that the controller \( u_j^{Z,\lambda} \) that renders the zero dynamics manifold \( Z_j \) invariant if:

\[
0 \equiv f_j(0, z) + g_j(0, z) u_j^{Z,\lambda}(0, z) + \bar{g}_e(0, z) \lambda_e
\]

where \( u_j^{Z,\lambda} \) implicitly depends on \( \lambda_e \) for \( \bar{e} = (j, i) \in \mathbb{E} \). By applying \( u_j^{Z,\lambda} \), we obtain a \( \lambda \)-coupled control subsystem (\( \lambda \)-CCSub) for the \( i \)th subsystem:

\[
C_i^{Z,\lambda} \triangleq \begin{cases} 
\dot{x}_i = f_i(x_i, z_i) + g_i(x_i, z_i) u_i + \bar{g}_i(x_i, z_i) \lambda_e \\
\dot{z}_i = p_i(x_i, z_i) + q_i(x_i, z_i) u_i + \bar{q}_i(x_i, z_i) \lambda_e \\
\lambda_e = -\lambda_e \\
\text{s.t. } c_i(z) = z_i - z_j \equiv 0, \quad \lambda_e = -\lambda_e
\end{cases}
\]

Thus, the \( i \)th subsystem evolves according to its own dynamics and the zero dynamics of all remaining systems—all of which are coupled via the coupling inputs \( \lambda \).

### III. ISOLATING CONTROL SUBSYSTEMS

The main idea in approaching the analysis and design of controllers for coupled control systems is to isolate subsystems that encode the behavior of the overall CCS. This section outlines the procedure for isolating the subsystems through a two-step approach: restricting systems to the zero dynamics manifold, and leveraging this to explicitly calculate the coupling conditions. We then can reduce the full-order CCS to a subsystem that no longer depends on the internal states of the other subsystem. We establish the main result of the paper encapsulating these constructions: solutions of the subsystem yield solutions of the full-order dynamics.

#### A. \( \lambda \)-Coupled Subsystem

Given a CCS \( C \), we define the **zero dynamics manifold** for each subsystem \( i \in \mathbb{N} \) as:

\[
Z_i \triangleq \{(x, z) \in \mathcal{X} \times \mathcal{Z} \mid x_i \equiv 0\}.
\]

Thus, the zero dynamics manifold for \( i \)th subsystem consists of the internal states, \( x_i \), being zero, i.e., the system evolves only according to the coupled states \( z \).

We wish to design controllers of the overall CCS on the zero dynamics of subsystem \( j \in \mathbb{N} \). Therefore, a controller \( u_j^{Z,\lambda}(x_j, z) \) is said to **render the zero dynamics manifold** \( Z_j^{\lambda} \) **invariant** if it satisfies the following algebraic condition:

\[
0 \equiv f_j(0, z_j) + g_j(0, z_j) u_j^{Z,\lambda}(0, z) + \bar{g}_e(0, z) \lambda_e
\]

where \( u_j^{Z,\lambda} \) implicitly depends on \( \lambda_e \) for \( \bar{e} = (j, i) \in \mathbb{E} \).
Theorem 1. Let $C$ be a CCS, and for the $i^{th}$ system assume there exist $u_{i}^{Z}$ that render the zero dynamics manifold $Z_{i}$ invariant. Let $C^{-}_{i}$ be the corresponding $\lambda$-CCSSub for $i^{th}$ subsystem. Given a feedback controller $u_{i}(x_{i},z)$ for the CCS with corresponding dynamical subsystem $D_{i}^{Z}$ with solution $(x(t),z(t))$ for $t \in I \subset \mathbb{R}$.

Proof: The condition that $(x(0), z(0)) \in C$ is equivalent to $c_{e}(z(0)) = 0$. Concretely, $c_{e}(z(0), z(0)) = 0$. Since $\lambda_{e}$ is a coupling relation, it satisfies (16) and more explicitly (17), therefore, and being explicit about the arguments, $\epsilon_{e}(x(t), z(t)) = 0$ for all $t \in I$ and $e \in E$. It follows that $c_{e}(z(t)) = 0$ for all $t \in I$ and $e \in E$.

Corollary 1. Under the conditions of Theorem 7 assume that $(x_{i}(t), z(t))$ is a periodic solution of $\mathcal{D}_{i}^{Z}$ with period $T > 0$ and corresponding orbit $O_{i} = \{(x_{i}(t), z(t)) \in \mathcal{X}_{i} \times \mathcal{Z} \mid 0 \leq t \leq T\}$. Then $(x(t), z(t), \lambda^{Z}(t))$ is a periodic solution of the CDS with period $T > 0$ and corresponding periodic orbit $O = \{(x(t), z(t), \lambda(t))\}$.

Application to quadrupeds. For the quadrupedal dynamics $R_{Q}$, since the output $q$ has (vector) relative degree 2 with respect to $u_{i}$ (see [19]), we can explicitly design the controller $u_{i}^{Z}$ that renders $Z_{i}$ invariant:

\[ u_{i}^{Z} = (J_{y_{i}}D_{i}^{-1}B_{i})^{-1}(J_{y_{i}}D_{i}^{-1}H_{i} - J_{y_{i}}q_{i}) = J_{y_{i}}^{T}q_{i} \]

as given by Lemma 1. Hence, this controller satisfies (11) and renders a $\lambda$-coupled CSub, as in (12).

For robotic systems, we take these ideas one step further to obtain “bipeds” that are the isolated subsystems associated with quadrupeds and include slack variables that are beneficial for gait generation. Operating on the invariant zero dynamics manifold $Z_{j}$ yields $y_{j}(q_{j}, \alpha_{j}) \equiv 0$, hence

\[ \theta_{a} \equiv H_{a}^{-1}y_{a}(\xi_{j}, \alpha_{j}) \]

and

\[ J_{y_{i}}^T q_{j}(\xi_{j}, \alpha_{j}) = J_{y_{i}}^{T}(\xi_{j}, \alpha_{j})^{-1} \]

where $J_{y_{j}} = \partial y_{j}(q_{j}, \alpha_{j})/\partial q_{j}$. In another word, if $u_{j}^{Z}$ exists and is applied to $j^{th}$ subsystem, the $j^{th}$ bipedal dynamics given by (19)-(20) are equivalent to:

\[ \begin{cases} D_{j}J_{y_{j}}^{T}(\xi_{j}, \alpha_{j}) + H_{j} = J_{y_{j}}F_{j} + B_{j}u_{j}^{Z} + J_{e}^{T}\lambda_{e} \\ J_{y_{j}}^{T}(\xi_{j}, \alpha_{j}) \end{cases} \]

(19)

where for simplicity we have suppressed the dependencies of $D_{j}(q_{j}(\xi_{j}), \alpha_{j})$ and $H_{j}(q_{j}(\xi_{j}), \alpha_{j})$ on $J_{y_{j}}(\xi_{j}, \alpha_{j})$. We then leverage a specific structure of rigid-body dynamics when using the floating base convention: $B_{j}^{T}H_{j} + J_{y_{j}}^{T}\lambda_{e} = (\lambda_{e}^{T}, u_{j}^{Z})^{T}$. Utilizing this, (20) and the first 6 rows of (19) yield the following “bipedal” dynamics:

\[ \begin{cases} D_{j}q_{j}^{T}(\xi_{j}, \alpha_{j}) + H_{j} = J_{y_{j}}F_{j} + J_{e}^{T}\lambda_{e} \\ J_{y_{j}}^{T}(\xi_{j}, \alpha_{j}) \end{cases} \]

(21)
IV. COUPLED SYSTEM OPTIMIZATION

With the previous construction of coupled control systems, we present a general optimization framework to solve for the solution of the $i^{th}$ CSub in (18) associated with the CCS, while synthesising the controllers that render forward invariance of the zero dynamics manifolds. The approach we will take is a locally direct collocation based optimization method [9], which has been widely applied to finding solutions to dynamical systems such as [14]. We now pose the method [9], which has been widely applied to finding solutions.

The solution of the optimization setup. We first discretized the time horizon $t \in [0, T]$ evenly to obtain the grid indices $\kappa = 0, 1, \ldots, K$, i.e., $t^\kappa = T\kappa/K$. We define the decision variable associated with the $i^{th}$ control subsystem $C_i^Z$ as:

$$\mathbf{X} \triangleq \{\vartheta^\kappa\}_{\kappa=0,1,\ldots,K}, \quad \vartheta^\kappa \triangleq \{x_i^\kappa,\dot{x}_i^\kappa, z_i^\kappa, \dot{z}_i^\kappa, u_i^\kappa, u_{Z_i}^\kappa\}$$

Note that we abbreviated the dependency on time $t$ as $\Box^\kappa \triangleq \Box(t^\kappa)$ for notational simplicity.

Recall that given a coupling relation, we have associated zero dynamics invariance conditions given by [14]. We will enforce these conditions in the optimization to ensure that $u_{Z_i}^\kappa$ renders $Z_j$ invariant as:

$$F_{\text{zero}}(\vartheta^\kappa) \triangleq f_j^Z(0, x_i^\kappa) + g_j^Z(0, z_i^\kappa)u_i^\kappa + g_j^Z(0, z_i^\kappa)(u_j^Z - u_{Z_i}^\kappa),$$

where $f_j^Z$ and $g_j^Z$ are given as in (15).

Next, following from the constructions in Sec III-C, we define constraints corresponding to the dynamics of the $i^{th}$ control subsystem $C_i^Z$ (as obtained from the coupling relation). Denote $\chi^\kappa = (x_i^\kappa, z_i^\kappa, \dot{z}_i^\kappa)$ and

$$F(\chi^\kappa, u_i^\kappa) \triangleq \begin{cases} f_j^Z(x_i^\kappa, z_i^\kappa) + g_j^Z(x_i^\kappa, z_i^\kappa)u_i^\kappa & \text{if } \chi_i^\kappa \text{ is periodic} \\ p_j^Z(x_i^\kappa, z_i^\kappa) + q_j^Z(x_i^\kappa, z_i^\kappa)u_i^\kappa & \text{if } \chi_i^\kappa \text{ is not periodic} \end{cases}$$

to obtain the dynamic constraints as

$$F_{\text{dyn}}(\vartheta^\kappa) \triangleq \dot{\chi}^\kappa - F(\chi^\kappa, u_i^\kappa) = 0,$$

which is an equality constraint imposed on the $\kappa^{th}$ node to allow all of the states and controllers satisfy the dynamics in (18). Further, to guarantee that those local solutions satisfying (C2) take on the same vector flow, i.e., belong to a unique solution, we employ an implicit stage-3 Runge-Kutta method for formulating this objective as an equality constraint. Concretely, we use Hermite interpolation to compute the interpolated value of $\chi_i^\kappa$ and its slope $\dot{\chi}_i^\kappa$ (see equation (30) of [9]) at the center of the subinterval $[t^\kappa, t^{\kappa+1}]$. Then the collocation constraints are formed as:

$$d(\chi^\kappa, \chi^{\kappa+1}, u_i^\kappa) \triangleq \dot{\chi}^\kappa - F(\chi^\kappa, u_i^\kappa) = 0 \quad \text{(C.3)}$$

Physical Inequality Constraints & Periodic Constraints. A set of inequality constraints (path constraints) $p(\vartheta^\kappa) \geq 0$ are used to enforce conditions along the time horizon. For robotics, these are widely applied as obstacle avoidance condition, and some feasibility conditions for the dynamical system, representing real-world physics. In our application — the walking dynamics of quadrupeds, the inequality constraints are used to define the friction cone condition and maximum ground clearance of the swing foot to be higher than 8 cm.

In addition, a set of equality constraints are imposed on the decision variables at $t = 0, T$ to “connect” the initial and final condition: $b(\chi^0, \chi^K) = 0$, so that the optimal solution of the optimization is a periodic solution of the dynamical system. Particularly, the dynamics of quadrupedal locomotion include both continuous and discrete dynamics, forming a hybrid control system. To find a periodic solution (ambling motion), we have the periodic constraint as:

$$b(q_i^0, \dot{q}_i^0, q_i^K, \dot{q}_i^K) = \left[\Delta(\chi^K - \chi^0) - \dot{q}_i^0\right] = 0 \quad \text{(C.6)}$$

where $\Delta(\cdot)$ represents the plastic impact dynamics that maps the pre-impact velocity $\dot{q}_i^K$ to its post-impact term.

Optimization problem. To find the periodic solution of dynamical system (18), we now parse this coupled controlling problem of the isolating $i^{th}$ subsystem as:

$$\text{argmin } \Phi(\mathbf{X})$$

subject to

- $F_{\text{zero}}(\vartheta^\kappa) = 0 \quad \kappa = 0, 1, \ldots, K \quad \text{(C.1)}$
- $F_{\text{dyn}}(\vartheta^\kappa) = 0 \quad \kappa = 0, 1, \ldots, K \quad \text{(C.2)}$
- $d(\chi^\kappa, \chi^{\kappa+1}, u_i^\kappa) = 0 \quad \kappa = 0, 1, \ldots, K-1 \quad \text{(C.3)}$
- $\dot{\chi}^\kappa \in \mathcal{X} \times \mathcal{Z} \times \mathcal{U} \quad \kappa = 0, 1, \ldots, K \quad \text{(C.4)}$
- $p(\vartheta^\kappa) \geq 0 \quad \kappa = 0, 1, \ldots, K \quad \text{(C.5)}$
- $b(\mathbf{X}) = 0 \quad \text{(C.6)}$

where $\Phi(\cdot) \in \mathbb{R}$ is the cost function. Here, we pick the cost function as the acceleration of the torso orientation to yield a less energetic motion for the ease of experiments. (C.4) defines the upper and lower bounds of the decision variables, i.e., that they live in the admissible space of values. In the application of walking, this was used to define the feasible configuration space and the actuator torque less than 40N-m.

The other constraints are as stated as above.

Solutions. As a result, the optimization (NLP) can simultaneously produce trajectories (solutions) of the states $\{x_i(t), z(t)\}, u_{Z_i}^\kappa(t)$ that renders the zero dynamics manifold $Z_j$ invariant and the open-loop controller $u_i(t), \forall t \in [0, T]$ for which these solutions are defined. Note that one can also enforce the dynamics $\dot{\chi}_i^\kappa + \varepsilon\chi_i^\kappa = 0$ with $\varepsilon > 0$ to guarantee the converging attribute of the $i^{th}$ isolating subsystem, in which case the controller $u_i(x_i, z)$ is equivalently an input-output feedback linearization controller. Per Theorem 1 given $u_{Z_i}^\kappa$ that renders invariant $Z_j$ and the feedback controller $u_i(x_i, z)$, we can compute $\lambda^Z(t)$ using (13), hence $\{(x_i(t), z(t), \lambda^Z(t))\}$ is a solution of the original CDS. Further, by imposing the periodic condition on the solution’s boundary condition, the optimization produced a periodic solution of period $T$ to the CCS. Therefore, according to Corollary 1 $(x_i(t), z(t), \lambda^Z(t))$ is a periodic solution of the CDS with period $T$.

Application to quadrupeds. When posing the control problem of quadrupeds, we leverage the subsystems representing the front and rear bipeds: $R_{F_i}^\kappa$ and $R_{R_i}^\kappa$, as given in (21). Note that these subsystems are still coupled through $\lambda$, while this could be explicitly solved for via Lemma 1 we keep it implicit due to the complexity of inverting the...
mass-inertia matrix for this particular robotic application. The $i^{th}$ subsystem yield (C.1), (C.2) and (C.3) for \( \text{NLP} \). Specifically for all of the grid indices $\kappa = 0, 1, \ldots, 5$, we have the decision variables: $\theta^\kappa = \{ q^\kappa, \dot{q}^\kappa, \ddot{q}^\kappa, \dot{\theta}^\kappa, \underline{u}^\kappa, F^\kappa, F^\kappa, \alpha^\kappa, \lambda^\kappa \}$. Finally, the optimization converged to a periodic solution of the isolated bipedal system, which can then be reconstructed to obtain the ambling motion of the quadrupedal robot (shown in Fig. 3) according to Theorem 1. We report that the computation took 17.6s and 295 iterations of searching. Comparing to the traditional full-model based approaches [10], whose fastest record was 42s, the proposed method is 58% faster.

To validate the proposed periodic orbit generation method using coupled control systems, we conducted experiments in indoor and outdoor environments, as well as in a physics engine —RaiSim. The implemented controller is a time-based PD approximation of input-output linearizing controllers to track the desired outputs (represented by $\alpha_1, \alpha_2 = \mathcal{M}(\alpha_1)$:

$$ u_i(q_i, \dot{q}_i, t) = -k_p(\dot{y}^a(q_i) - \dot{y}_i(t, \alpha_i)) - k_d(y^a(q_i) - y_i(t, \alpha_i)) $$

with $k_p, k_d$ the PD gains. The result is successful ambling in simulation, indoor (research lab) environment and outdoor rough terrains. See [1] for the video and Fig. 3 for walking tiles and a comparison for the logged data with the optimized trajectory generated from \( \text{NLP} \). Importantly, we note that the averaged absolute torque inputs are 9.47, 6.45, 17.56 N·m for the hip roll, hip pitch and knee motors, all of which are within the hardware limitations. Thus we are able to translate the theoretic results on gait generation for coupled control systems to hardware in a physically realizable fashion.

V. CONCLUSION

As inspired by robotic systems, this paper presented the new formulation of coupled control systems: control systems that are connected via coupling relations and coupling inputs. We demonstrated how these systems can be reduced to a single subsystem that encodes the behavior of the full-order coupled system; this was achieved through leveraging zero dynamics and coupling relations. The main result of this paper was that solutions for these isolated subsystems are solutions for the full-order systems. Building on this, we constructed a nonlinear optimization problem on only a given subsystem that yields periodic orbits for the full-order dynamics. Finally, the application of these ideas were considered for coupled control systems from which a specific example includes quadrupeds. This was demonstrated through experiments on hardware. An important future direction of this work is to expand the coupled control system related concepts to system with more than two subsystems.
