Abstract

During an interaction the tendency of speakers to change their speech production to make it more similar to their interlocutor’s speech is called convergence. Convergence had been studied due to its relevance for cognitive models of communication as well as for dialogue system adaptation to the user. Convergence effects have been established on controlled data sets while tracking its dynamics on generic corpora has provided positive but more contrasted outcomes. We propose to enrich large conversational corpora with dialogue acts information and to use these acts as filters to create subsets of homogeneous conversational activity. Those subsets allow a more precise comparison between speakers’ speech variables. We compare convergence on acoustic variables (Energy, Pitch and Speech Rate) measured on raw data sets, with human and automatically data sets labelled with dialog acts type. We found that such filtering helps in observing convergence suggesting that future studies should consider such high level dialogue activity types and the related NLP techniques as important tools for analyzing conversational interpersonal dynamics.

1 Introduction

The way participants engaged in a conversation speak tends to vary depending on their interlocutor’s speech. The tendency to co-adjust speaking styles in response to the partner speaking style is known as convergence. Convergence is presented in general and influential models of communication such as accommodation theory (Giles et al., 1991) or interactive alignment (Pickering and Garrod, 2004). This variation due to the other party has been studied for many levels of speech and language, for example in phonology (Street, 1984; Pardo, 2006) or in prosody (Levitan and Hirschberg, 2011; Truong and Heylen, 2012; Bonin et al., 2013).

Our approach aims at deepening and generalizing the investigation of convergence and related effects in real-life corpora. Considered from the angle of speech and linguistic variables, an essential aspect of conversations is their extreme variability. This is due to a large extent to different conversational activities speakers can participate in. For instance, they can enter in a storytelling sequence in which one interlocutor starts to produce mostly back-channels (Yngve, 1970) while the main speaker develops lengthy monologues. This variability makes comparison of values across participants very problematic. We propose to create subsets of similar dialogues acts (DA) (e.g. ’statements’ and ’back-channels’, see Table 1 for an illustration), resulting in homogeneous data used as a proxy to characterize the conversational activity of a given turn. We intend to create subsets consisting of turns belonging to a specific function using current Dialogue Act tagging Techniques.

Our work concerns more specifically acoustic convergence. Our definition of convergence comes from several studies (Edlund et al., 2009; Truong and Heylen, 2012; Cohen Priva et al., 2017), and consists of comparing distance between speakers in different parts of a conversation (See Section 3). We do not claim it is the best measure to approach inter-personal dynamics (See (Priva and Sanker, 2019)) but it is an interesting way to assess convergence within a conversation and it allows to test whether our DA based approach can help this domain.

2 Related work

Convergence has been approached at different granularity levels and for a large range of variables. In terms of granularity, studies can be Inter-conversation comparisons or Intra-conversation
While a large body of carefully controlled experiments on lab speech provided results on convergence, the results on real corpora (from the studies listed in the previous paragraph) provide a more complex picture, with a relative fragility of the effects (Fuscone et al., 2018) and raised methodological comments (See (Truong and Heylen, 2012) and (Cohen Priva and Sanker, 2018)). More precisely, for intra-conversation studies, (Edlund et al., 2009) found that participants tend to be more similar (in terms of gaps and pauses duration) to their partners than chance would predict. However, the absence of significant results in comparing the inter-speaker distance in the first and second halves of the conversations makes the authors conclude that convergence cannot be captured with such an approach. (Truong and Heylen, 2012) conducted a similar experiment (on intensity and pitch) on English MapTask ((Anderson et al., 1991)) with partial positive results. The dynamic nature of the phenomenon as well as the social factors render such studies difficult to be performed. These two studies were grounded on conversational corpora that are sizeable but not huge (6 x 20 minutes for the (Edlund et al., 2009); and about 60 MapTasks dialogues for (Truong and Heylen, 2012). (Cohen Priva and Sanker, 2018) used the much bigger Switchboard corpora. Second, to account for strategic adaptation one must take precise care of speaker profiles. Our approach therefore focuses on relatively low level variables to avoid as much as possible the ”adaptation” part of the interpersonal dynamics. Third, similarly to (Cohen Priva et al., 2017) our approach is based on a large conversational corpus with the intention of overcoming noise and effect small magnitude by increasing the amount of data considered.

3 Methodology

3.1 Convergence

Following (Edlund et al., 2009) and (Truong and Heylen, 2012) we divide each conversation into two halves and compare the distance between the average values of the target variables of each speaker. This provided us two values (first and second interval) for each variable and each conversation: $\Delta V_i = |V_{Ai} - V_{Bi}|$, where $i = 1, 2$ refers respectively to the first and second interval. $A$ and $B$ indicate the speakers who take part in the conversation while $V$ corresponds to Energy (E), Pitch (F0) and Speech rate (SR). Our aim is to test the hypothesis that convergence occurs during the interaction. We therefore computed the distance between both intervals, resulting in a distribution of these values in both intervals for the whole corpus. We then fitted a linear mixed regression model of the evolution. We use the lme4 library in R (Bates et al., 2014) to fit the models and provide t-values. The lmerTest package (Kuznetsova et al., 2014), which encapsulates lme4, was used to estimate degrees of freedom (Satterthwaite approximation) and calculate p-values. In the model, the $\Delta V_i$ is the predicted value, the A and B identities as well as the topic of the conversation are set.
as random intercepts. The model, in $\mathbb{R}$ notation, is $\Delta V_i \sim t_i + (1 \mid \text{topic}) + (1 \mid \text{speaker}_A) + (1 \mid \text{speaker}_B)$.

3.2 Feature processing

E and F0 are computed from the audio files with openSMILE audio analysis tool (Eyben and Schuller, 2015) while SR is computed using time aligned transcripts.

Energy (E): One of the issues of telephonic conversation is the distance mouth-microphone that affects measured values of voice intensity can be different across speakers and even for the same speaker across conversations. So to reduce this effect we introduce a normalization factor by dividing each speaker E values by the average E produced by that speaker in the entire conversation. In addition, to reduce the environmental noise, we computed the average E using the temporal windows where the probability of voicing is above 0.65. Then we computed for each conversational unit (as provided by Switchboard transcripts) the average E.

Pitch (F0): We computed the average in each conversational unit for each speaker.

Speech Rate (SR): We used the approach proposed by Cohen-Priva (Cohen Priva et al., 2017) that defines SR for an utterance as the ratio between the actual duration of the utterance and its expected duration (computed by estimating every word duration into the whole corpus, for all speakers). Values above / below 1 correspond respectively to fast / slow speech compare to the average of the corpus.

In order to make the measure SR more reliable we consider only utterances having more than 5 tokens.

4 Dialogue Act Filtering and Data Sets

Switchboard (SWBD) (Godfrey et al., 1992) is a corpus of telephonic conversations between randomly assigned speakers of American English discussing a preassigned topic. The corpus consists of 2430 conversations (of an average duration of 6 minutes) for a total of 260 hours, involving 543 speakers. The corpus has audio, time aligned transcripts and a segmentation into utterances.

642 Switchboard conversations have been segmented and annotated for DA that we will call the NXT data set (Calhoun et al., 2010). The DA-tagged set has been simplified to 42 tags but a few of them are dominating the distribution (Statement: 36%, Acknowledgment: 19%, Opinion: 13%), illustrated in Table 1. See (Stolcke et al., 1998) for details.

| DA type     | Example                      |
|-------------|------------------------------|
| Statement   | “that was pretty heartrending for her” |
| Opinion     | “money seems to be too big of an issue.” |
| Backchannel | “Uh-huh.”                    |
| Agree.      | “you’re right”                |

Table 1: Examples for the DA types used.

Automatically tagged data set We create a turn tagger, using 3 categories, corresponding to Statement+Opinion (STA+OPI), Backchannel+Agreement (BAC+AGR) and Other (OTH) which includes all the other DA. This grouping was obtained by first considering only the DA dominating the distribution. Then we manually checked many examples of each DA and figure out that although functionally different statements and opinions on the hand; and backchannel and Agreement those group were similar enough for our current purposes. The former has a main speaker nature while the later have a much more listener nature (see Table 1).

We used as train, development and test set the NXT Switchboard corpus that contains annotated DA for 642 conversations. Since the DA segmentation does not match the turn segmentation, we label each turn of the corpus by assigning the majority class, among the DA tags used in the turn. The resulting distribution is 52% STA+OPI, 25% BAC+AGR and 23% of OTH. The model we used is described in ((Auguste et al., 2018)) and inspired by the model of ((Yang et al., 2016)). It is a two levels hierarchical neural network (with learning rate = 0.001, batch size = 32, max length of each turn = 80, embeddings words dimension = 200). In the first level each turn is treated taking into account the words that form the turn while the second level is used to take into account the whole turn in the context of the conversation. Each level is a bidirectional Long Short Term (LSTM). We used 80% of Switchboard data as training set, 10% for development and 10% for the test set. The F1 score

---

1Speakers therefore do not know each other. 

2We use this version of DA as it contains alignment to the transcripts, contrarily to the SWDA bigger data set (Jurafsky et al., 1997).
of the DA tagger is 81% on the test set, the details for each category is reported in table 2. The F1 score of the class OTH is low compared to the other 2 classes.

| Class      | Precision | Recall | F1  |
|------------|-----------|--------|-----|
| Bc+Agr.    | 0.88      | 0.85   | 0.86|
| St.+Opi.   | 0.84      | 0.92   | 0.87|
| Oth.       | 0.62      | 0.49   | 0.55|

Table 2: Prediction score of our turn tagger.

5 Results

Our question is whether we can observe more reliably interpersonal dynamics in raw, manually DA-tagged (small) or automatically DA-tagged (large) data sets. An underlying question is whether the noise introduced by the DA-tagging uncertainty and/or the data size reduction is compensated by the gain in homogeneity between the material that is compared.

5.1 DA-tagging contribution

We first report the results in the case of the whole data set without DA (SWBD) and manually DA-tagged (NXT). The results are summarized in Table 3.

|                | All | St. + Opi. | Bc. + Agr. |
|----------------|-----|------------|------------|
| SWBD (180h)    | E - R | X          | X          |
| NXT (41h)      | E - X | E - R (17h)| E - - (7h) |

Table 3: Manual tagging results summary (E: Energy; P: Pitch; R: Speech Rate; - : no significance; normal font : p-value ≤0.05 ; bold : p-value ≤0.01). See Table 5 in Appendix for details.

When differences are significant, it is always in the direction of reduction of the distance (See Appendix for the details). We observe that concerning Statement, with less than 10% of the original data, the method allows one to observe the same effect as in the whole Switchboard (and reaches a higher level of significance for SR). The Statement subset shows convergence for E and SR. Statement-filter seems to homogenize the data set by filtering out particular back-channels and strong disfluencies (type abandoned). This helps observing the effect for SR. Contrarily, the wide variety of statements in terms of utterance duration could be an issue for F0 since contours and physiological-related decreasing slope could result in a lot of noise for this variable. There are no positive results on Opinion maybe due to larger variability or consistency in this label. Back-channel although keeps the effect on the E but, due the nature of this speech act, SR is not relevant. F0 doesn’t show any significant results. This probably can be explained considering that F0 is a more complex variable and the average approach is not able to capture more subtle characteristics of F0 (Reichel et al., 2018).

5.2 Automatic Tagging results

As explained above, in the experiment on automating tagging we merged the most similar frequent DA. The automatically tagged corpus preserved the results from the raw data sets. Similarly for the manual version, automatic tags filtering helped reaching better significance for SR on Statement+Opinion utterances as summed-up in Table 4. Back-channels were excluded from the SR experiment since our measure of SR isn’t reliable on such short utterances.

|                | All | St. + Opi. | Bc. + Agr. |
|----------------|-----|------------|------------|
| SWBD (180h)    | E - R | X          | X          |
| Auto           | E - R | E - R      | E - X      |

Table 4: Automatic tagging results summary (E: Energy; P: Pitch; R: Speech Rate; - : no significance; normal font : p-value ≤0.05 ; bold : p-value ≤0.01). See Table 6 in Appendix for details.

6 Discussion

We scrutinized convergence during the course of a conversation and in a real world setting (Switchboard corpus). The positive results in our experiments complement the picture provided by the literature by showing that convergence effects do happen in the time course of conversation of generic corpus. Moreover, we open up the possibility of a range of new studies taking advantage on arbitrary large corpora partially controlled a posteriori thanks to automatic dialogue act tagging.
