Abstract

Pattern avoidance classes of permutations that cannot be expressed as unions of proper subclasses can be described as the set of subpermutations of a single bijection. In the case that this bijection is a permutation of the natural numbers a structure theorem is given. The structure theorem shows that the class is almost closed under direct sums or has a rational generating function.

Keywords: Restricted permutations, pattern avoidance, subpermutations.

1 Introduction

Classes of permutations defined by their avoiding a given set of permutation patterns have been intensively studied within the last decade. Quite often the issue has been to determine the number of permutations of each length in the class. In order to do this it is necessary to derive structural properties of the permutations in the class starting from the avoided set. However, there are very few general techniques for obtaining such structural information. This paper is a contribution towards a general structure theory. We begin from the point of view that pattern-avoidance classes can be expressed as unions of atomic classes (those that have no non-trivial expression as a union). We shall show that these atomic classes are precisely the classes that arise as the set of restrictions of some injection from one ordered set to another. In general the order types of these two sets provide some information about the atomic class. The major part of our paper is a characterisation of such injections and classes in the simplest case: when the order types are those of the natural numbers.
In the remainder of this section we review the terminology of pattern avoidance classes. Most of this terminology is standard in the subject except for the notion of a *natural* class. We shall see a number of conditions on pattern avoidance classes that are equivalent to their being atomic and we shall exhibit examples of atomic and non-atomic classes. These conditions and examples motivate the notion of a natural class whose elementary properties we explore in Section 2. Section 3 contains our main result: a characterisation of natural classes, and Section 4 gives some further examples.

We need a small number of definitions concerned with permutations and sets of permutations. For our purposes a permutation is just an arrangement of the numbers 1, 2, ..., n for some n. We shall often need to consider arrangements of other sets of numbers and we shall refer to these as sequences; so, unless stated otherwise, a sequence will mean a list of distinct numbers.

Two finite sequences of the same length \( \alpha = a_1a_2a_3 \cdots \) and \( \beta = b_1b_2b_3 \cdots \) are said to be order isomorphic (denoted as \( \alpha \cong \beta \)) if for all \( i, j \) we have \( a_i < a_j \) if and only if \( b_i < b_j \). Any sequence defines a unique order isomorphic permutation; for example 7496 \( \cong 3142 \).

A sequence \( \alpha \) is said to be involved in a sequence \( \beta \) (denoted as \( \alpha \preceq \beta \)) if \( \alpha \) is order isomorphic to a subsequence of \( \beta \). Usually, involvement is defined between permutations; for example 1324 \( \preceq 146325 \) because of the subsequence 1435.

It is easily seen that the involvement relation is a partial order on the set of all (finite) permutations. We study it in terms of its order ideals which we call closed sets. A closed set \( X \) of permutations has the defining property that if \( \alpha \in X \) and \( \delta \preceq \alpha \) then \( \delta \in X \).

Closed sets are most frequently specified by their basis: the set of permutations that are minimal subject to not lying in the closed set. Once the basis \( B \) is given the closed set is simply

\[
\{ \sigma \mid \beta \not\preceq \sigma \text{ for all } \beta \in B \}
\]

and we shall denote it by \( A(B) \).

Closed sets arise in the context of limited capability sorting machines such as networks of stacks, queues and deques with a point of input and a similar output. Here the basis consists of minimal sequences that cannot be sorted into some desirable order. As sequences can be sorted if and only if they do not involve any basis elements, basis elements are frequently referred to as “forbidden patterns” and the set of permutations that can be sorted by such a mechanism is described as the set of all permutations that “avoid” that basis.

Much of the thrust of this paper is in specifying closed sets in a different way. Suppose that \( A \) and \( B \) are sets of real numbers and let \( \pi \) be an injection from \( A \) to \( B \). Then every finite subset \( \{ c_1, c_2, \ldots, c_n \} \) of \( A \), where \( c_1 < c_2 < \ldots < c_n \) maps to a sequence \( \pi(c_1) \pi(c_2) \ldots \pi(c_n) \) which is order isomorphic to some permutation. The set of permutations that arise in this way is easily seen to be closed and we denote it by \( \text{Sub}(\pi : A \to B) \). In many cases the domain and
range of π are evident from the context in which case we write simply Sub(π). Also, since we may always replace B by the range of π we shall, from now on, assume that π is a bijection.

**Example 1.1** Let \( A = \{1 - 1/2^i, 2 - 1/2^i \mid i = 1, 2, \ldots\} \) and \( B = \{1, 2, \ldots\} \). Let π be defined by:

\[
\pi(x) = \begin{cases} 
2i - 1 & \text{if } x = 1 - 1/2^i \\
2i & \text{if } x = 2 - 1/2^i
\end{cases}
\]

Then it is easily seen that any finite increasing sequence of elements in \( A \) maps to an increasing sequence of odd integers followed by an increasing sequence of even integers. From this it follows readily that the permutations of \( \text{Sub}(\pi : A \to B) \) are precisely those that consist of two increasing segments. As shown in [2] this closed set has basis \( \{321, 3142, 2143\} \). Notice that \( A \) and \( B \) have order types \( 2\omega \) and \( \omega \). This particular closed set cannot be defined as \( \text{Sub}(\pi : A \to B) \) with both \( A \) and \( B \) having order type \( \omega \).

We now give several conditions on a closed set equivalent to it being expressible as \( \text{Sub}(\pi : A \to B) \).

**Theorem 1.2** The following conditions on a closed set \( X \) are equivalent:

1. \( X = \text{Sub}(\pi : A \to B) \) for some sets \( A, B \) and bijection \( \pi \).
2. \( X \) cannot be expressed as a union of two proper closed subsets.
3. For every \( \alpha, \beta \in X \) there exists \( \gamma \in X \) such that \( \alpha \preceq \gamma \) and \( \beta \preceq \gamma \).
4. \( X \) contains permutations \( \gamma_1 \preceq \gamma_2 \preceq \cdots \) such that, for every \( \alpha \in X \), we have \( \alpha \preceq \gamma_n \) for some \( n \).

**Proof:**

1 \( \Rightarrow \) 2. Suppose \( X = \text{Sub}(\pi : A \to B) \) and yet there exist proper closed subsets \( Y, Z \) of \( X \) such that \( X = Y \cup Z \). Then there exist permutations \( \rho \in X \setminus Y \) and \( \sigma \in X \setminus Z \). Therefore we can find subsequences \( r_1 < r_2 < \cdots \) and \( s_1 < s_2 < \cdots \) of \( A \) which are mapped by \( \pi \) to subsequences order isomorphic to \( \rho \) and \( \sigma \). The union of \( \{r_1, r_2, \ldots\} \) with \( \{s_1, s_2, \ldots\} \) defines a sequence \( t_1 < t_2 < \cdots \) that is mapped by \( \pi \) to a subsequence order isomorphic to a permutation \( \tau \in X \). Obviously, \( \rho \preceq \tau \) and \( \sigma \preceq \tau \). However \( \tau \) belongs to at least one of \( Y \) or \( Z \), say \( \tau \in Y \). Since \( X \) is closed we have \( \rho \in Y \), a contradiction.

2 \( \Rightarrow \) 3. Suppose that there exist \( \alpha, \beta \in X \) with the property that no permutation of \( X \) involves both of them. Put

\[
Y = \{ \gamma \in X \mid \alpha \not\preceq \gamma \}
\]

\[
Z = \{ \gamma \in X \mid \beta \not\preceq \gamma \}
\]
Then $Y$ and $Z$ are proper closed subsets of $X$ whose union is $X$ (since any $\gamma \in X \setminus (Y \cup Z)$ would involve both $\alpha$ and $\beta$).

3 $\Rightarrow$ 4. If $\theta, \phi$ are two permutations in $X$ we know that there exists a permutation of $X$ that involves both.Temporarily we shall use the notation $\theta \vee \phi$ to denote one of these permutations. Now let $\beta_1, \beta_2, \ldots$ be any listing of the permutations of $X$. We define a sequence of permutations of $X$ as follows: $\gamma_1 = \beta_1$ and, for $i \geq 2$, $\gamma_i = \gamma_{i-1} \vee \beta_i$. Obviously, $\gamma_1 \preceq \gamma_2 \preceq \cdots$ and, for each permutation $\beta_n \in X$, $\beta_n \preceq \gamma_n$.

4 $\Rightarrow$ 1. In the sequence $\gamma_1 \preceq \gamma_2 \preceq \cdots$ we remove duplicates (if any) and we insert suitable permutations so that we have one of every degree. This gives a sequence of permutations $\alpha_1 \preceq \alpha_2 \preceq \cdots$ such that

1. $|\alpha_i| = i$,
2. $\alpha_i \in X$,
3. for all $\sigma \in X$ there exists some $\alpha_i$ with $\sigma \preceq \alpha_i$.

Now we shall inductively define, for each $i$, sets $A_i, B_i$ and bijections $\pi_i : A_i \to B_i$ with the following properties:

1. $|A_i| = |B_i| = i$
2. $\pi_i$ is order isomorphic to $\alpha_i$
3. $A_{i-1} \subset A_i$ and $B_{i-1} \subset B_i$
4. $\pi_i|_{A_{i-1}} = \pi_{i-1}$

Once these sets have been constructed we can complete the proof by setting $A = \bigcup_i A_i$ and $B = \bigcup_i B_i$. Then we define $\pi : A \to B$ for any $a \in A$ by finding some $A_i$ for which $a \in A_i$ and setting $\pi(a) = \pi_i(a)$; by the last two properties $\pi$ is well-defined. The second property guarantees that $X = \text{Sub}(\pi : A \to B)$.

To carry out the construction we shall define $A_i, B_i$ as subsets of the open interval $(0, 1)$. We begin by setting $A_1 = B_1 = 1/2$ and $\pi_1(1/2) = 1/2$. Suppose now that $A_i, B_i, \pi_i$ have been constructed for $i = 1, 2, \ldots, n$. The permutation $\alpha_{n+1}$ is constructed from $\alpha_n$ by the insertion of a new element $t$ at position $s$ in $\alpha_n$; the position numbers of all the elements of $\alpha_n$ which are greater than or equal to $s$ have to be increased by 1 and those values which are greater than or equal to $t$ have also to be incremented by 1.

We reflect this insertion in the definition of $A_{n+1}, B_{n+1}$ and $\pi_{n+1}$. The set $A_{n+1}$ is formed by augmenting $A_n$ with another number $a$ whose value lies between its $(s-1)^{th}$ and $s^{th}$ elements (if $s = 1$ we take $a$ between 0 and the minimal element of $A_n$; while if $s = n$ we take $a$ between the maximal element and 1). Similarly $B_{n+1}$ is formed by augmenting $B_n$ with a number $b$ whose value lies between its $(t-1)^{th}$ and $t^{th}$ elements. Then we define $\pi_{n+1}$ so that it agrees with $\pi_n$ on the elements of $A_n$ and has $\pi_{n+1}(a) = b$. ■
Because of this result we call closed sets of the form \( \text{Sub}(\pi : A \rightarrow B) \) atomic on the grounds that they cannot be decomposed as a proper union of two closed subsets. Expressing a given closed set as a union of atomic sets is often very useful in discovering structural information.

**Example 1.3** (See [2]) \([321, 2143] = [321, 2143, 3142] \cup [321, 2143, 2413]\)

Given an arbitrary closed subset one might hope to find its properties by first expressing it as a union of atomic sets, and then discovering properties of the bijection \( \pi \) associated with each atomic subset. Many difficulties impede this approach. It may happen that a closed set cannot be expressed as a finite union of atomic subsets. Moreover an atomic closed set may have a defining bijection \( \pi \) whose domain and range have high ordinal type; in that case one might be hopeful that properties of these ordinals (in particular, limit points) might imply properties of \( X = \text{Sub}(\pi : A \rightarrow B) \). Despite this hope it seems sensible to begin the systematic study of atomic sets by looking at the case where the ordinal type of both \( A \) and \( B \) is that of the natural numbers \( \mathbb{N} \).

## 2 Natural classes and sum-complete classes

A **natural class** is a closed set of the form \( \text{Sub}(\pi : \mathbb{N} \rightarrow \mathbb{N}) \). In other words, starting from a permutation \( \pi \) of the natural numbers, we form all the finite subsequences of \( \pi(1), \pi(2), \ldots \) and define a natural class as consisting of the permutations order isomorphic to these subsequences. From now on we shall use the notation \( \text{Sub}(\pi) \) (suppressing a notational reference to the domain and range of \( \pi \)) in the following circumstances

1. when \( \pi \) is an infinite permutation with \( \mathbb{N} \) as its domain and range,
2. when \( \pi \) is a finite permutation (in which case the domain and range are \( \{1, 2, \ldots, n\} \) where \( n \) is the degree of \( \pi \)).

**Example 2.1** Let \( \pi \) be defined by:

\[
\pi = 1 \ 3 \ 2 \ 6 \ 5 \ 4 \ 10 \ 9 \ 8 \ 7 \ \ldots
\]

Then \( \text{Sub}(\pi) \) is easily seen to be the set of all layered permutations as defined in [5].

If \( \alpha = a_1a_2 \cdots a_m \) and \( \beta = b_1b_2 \cdots \) are sequences (in particular, permutations) then their **sum** \( \alpha \oplus \beta \) is defined to be the permutation \( \gamma \delta \) where the segments \( \gamma \) and \( \delta \) are rearrangements of \( 1, 2, \ldots, m \) and \( m + 1, m + 2, \ldots \) respectively, and \( \alpha \cong \gamma \) and \( \beta \cong \delta \). Notice that we do not require that \( \beta \) be a finite permutation. If a permutation can be expressed as \( \alpha \oplus \beta \) (with neither summand empty) we
say that it is *decomposable*; otherwise it is said to be *indecomposable*. We also extend the sum notation to sets by defining, for any two sets of permutations \( X \) and \( Y \),

\[
X \oplus Y = \{ \sigma \oplus \tau \mid \sigma \in X, \tau \in Y \}
\]

A set \( X \) of permutations is said to be *sum-complete* if for all \( \alpha, \beta \in X \), we have \( \alpha \oplus \beta \in X \).

Sum-completeness and decomposability are linked by the following result, proved in \([3]\).

**Lemma 2.2** Let \( X \) be a closed set with basis \( B \). Then \( X \) is sum-complete if and only if \( B \) contains only indecomposable permutations.

We shall see that natural classes and sum-complete closed sets are closely connected. The first hint of this connection is the following result which, in particular, shows that every sum-complete closed set is a natural class.

**Proposition 2.3** Let \( \gamma \) be any (finite) permutation and \( S \) any sum-complete closed set. Then \( \text{Sub}(\gamma) \oplus S \) is a natural class.

**Proof:** Let \( \beta_1, \beta_2, \ldots \) be any listing of the permutations of \( S \). Consider the sequence of permutations

\[
\gamma \preceq \gamma \oplus \beta_1 \preceq \gamma \oplus \beta_1 \oplus \beta_2 \preceq \gamma \oplus \beta_1 \oplus \beta_2 \oplus \beta_3 \preceq \cdots
\]

Since \( S \) is sum-complete all these permutations lie in \( \text{Sub}(\gamma) \oplus S \). On the other hand it is clear that every permutation of \( \text{Sub}(\gamma) \oplus S \) is involved in some term of the sequence. Hence \( \text{Sub}(\gamma) \oplus S \) satisfies condition 4 of Theorem 1.2 and hence is atomic. Furthermore, the proof of (4\( \Rightarrow \)1) in Theorem 1.2 tells us how to express \( \text{Sub}(\gamma) \oplus S \) in the form \( \text{Sub}(\pi : A \to B) \). Following this recipe, it is easy to see that both \( A \) and \( B \) are (isomorphic to) \( \mathbb{N} \), and we have a natural class, as required.

Notice that the proof of this result makes no assumption on the listing of the elements of \( S \). That means that the infinite permutation \( \pi \) for which \( \text{Sub}(\gamma) \oplus S = \text{Sub}(\pi) \) is very far from being unique.

In the remainder of the paper we shall be exploring a partial converse of Proposition 2.3. Our main theorem will show that every finitely based natural class \( X \) does have the form of the proposition unless \( \pi \) and \( X \) have a very particular form.

### 3 A characterisation of natural classes

This section is devoted to the proof of the following theorem.
**Theorem 3.1** Let $X$ be a finitely based natural class. Then either

1. $X = \text{Sub}(\gamma) \oplus S$ where $\gamma$ is a finite permutation and $S$ is a sum-complete closed class determined uniquely by $X$, or

2. $X = \text{Sub}(\pi)$ where $\pi$ is unique and ultimately periodic in the sense that there exist integers $N$ and $P > 0$ such that, for all $n \geq N$, $\pi(n + P) = \pi(n) + P$.

The proof of the theorem will show precisely how $X$ determines $S$ in the first alternative. It will also, in the case of the second alternative, prove that $X$ is enumerated by a rational generating function.

Before embarking on a series of lemmas that lead up to the proof of Theorem 3.1 we shall define some notation that will be in force for the rest of this section.

We shall let $X = \text{Sub}(\pi)$ where $\pi$ is a permutation of $\mathbb{N}$. The basis of $X$ will be denoted by $B$ and we let $b$ denote the length of a longest permutation in $B$. The permutations of $B$ have a decomposition into sum components; the set of final components in such decompositions will be denoted by $C$.

We shall use the notation $A(C)$ for the closed set of all permutations that avoid the permutations of $C$. This is a slight extension of the notation we defined in Section 4 because $C$ might not be the basis of $A(C)$ ($C$ might contain some non-minimal elements outside $A(C)$). This causes no technical difficulties. Obviously, as every permutation that avoids the permutations of $C$ also avoids the permutations of $B$, we have $A(C) \subseteq X$. By Lemma 2.2, $A(C)$ is sum-complete; it is, as we shall see, the sum-complete class $S$ occurring in the statement of Theorem 3.1.

From time to time we shall illustrate our proof with diagrams that display permutations. These diagrams are plots in the $(x, y)$ plane. A permutation $p_1, p_2, \ldots$ (which maps $i$ to $p_i$) will be represented by a set of points whose coordinates are $(i, p_i)$. As a first use of such diagrams we have Figure 1 which illustrates the sum operation and the two alternatives in Theorem 3.1.

**Lemma 3.2** There exists an integer $k$ such that, for all $d > k$,

$$\text{Sub}(\pi(d), \pi(d + 1), \ldots) = A(C)$$

**Proof:** For each $\gamma \in C$ there is a basis element of $X$ of the form $\beta \oplus \gamma$. Every such $\beta$ is a permutation of $X$ and so we can choose a subsequence $S(\beta)$ of $\pi$ with $S(\beta) \cong \beta$. Let $t$ be the maximal value occurring in all such $S(\beta)$ and let $u$ be the right-most position of $\pi$ where an element of some $S(\beta)$ occurs.

There exists an integer $k > u$ such that all terms $\pi(k + 1), \pi(k + 2), \ldots$ exceed $t$. Note that the order type of $\mathbb{N}$ is used in establishing the existence of $k$. Among the terms $\pi(k + 1), \pi(k + 2), \ldots$ there can be no subsequence order isomorphic
to an element of \( C \). This proves that \( \text{Sub}(\pi(d), \pi(d + 1), \ldots) \subseteq \mathcal{A}(C) \) for all \( d > k \). It also proves that \( \mathcal{A}(C) \) is non-empty.

Now let \( \theta \in \mathcal{A}(C) \). Since the permutation 1 lies in \( \mathcal{A}(C) \) and \( \mathcal{A}(C) \) is sum-complete we have \( 1, 2, \ldots, d - 1 \oplus \theta \in \mathcal{A}(C) \). Therefore \( \pi \) has a subsequence order isomorphic to this permutation and that implies that \( \pi(d), \pi(d + 1), \ldots \) has a subsequence order isomorphic to \( \theta \) which completes the proof.

**Corollary 3.3** Either \( X = \text{Sub}(\gamma) \oplus \mathcal{A}(C) \) for some finite permutation \( \gamma \), or \( \pi \) has finitely many components and the last component (which is necessarily infinite) involves an element of \( C \).

**Proof:** Let \( \pi = \pi_1 \oplus \pi_2 \oplus \cdots \) be the sum decomposition of \( \pi \). Lemma 3.2 tells us, in particular, that there is a maximal position \( k \) where a subsequence order isomorphic to an element of \( C \) can begin. Suppose this position occurs in the sum component \( \pi_r \). If \( \pi_r \) is not the final component of \( \pi \) then we have \( \text{Sub}(\pi) = \text{Sub}(\pi_1 \oplus \cdots \oplus \pi_r) \oplus \text{Sub}(\pi_{r+1} \oplus \cdots) \). However \( \gamma = \pi_1 \oplus \cdots \oplus \pi_r \) is finite and \( \text{Sub}(\pi_{r+1} \oplus \cdots) = \mathcal{A}(C) \) by the lemma.

The first alternative of this corollary leads to the first alternative of Theorem 3.1 because of the following uniqueness result.

**Proposition 3.4** If \( X = \text{Sub}(\gamma_1) \oplus S_1 = \text{Sub}(\gamma_2) \oplus S_2 \) where \( \gamma_1, \gamma_2 \) are finite permutations and \( S_1, S_2 \) are sum-complete then \( S_1 = S_2 \).

**Proof:** Let \( \sigma_1 \in S_1 \). Then, as \( S_1 \) contains every permutation of the form \( \iota_m = 1 \ 2 \ \ldots \ 3 \), \( S_1 \) also contains \( \iota \oplus \sigma_1 \) where \( t = |\gamma_2| \). But this permutation
belongs to \( \text{Sub}(\gamma_2) \oplus S_2 \) and so can be expressed as \( \gamma' \oplus \sigma_2 \) where \( \gamma' \preceq \gamma_2 \). Since \( \iota_t \oplus \sigma_1 = \gamma' \oplus \sigma_2 \) and \( |\gamma'| \leq |\iota_t| \) we have \( \sigma_1 \preceq \sigma_2 \). This proves that \( \sigma_1 \in S_2 \) and therefore \( S_1 \subseteq S_2 \). The result now follows by symmetry.

In the remainder of the proof of Theorem 3.1 we shall assume that the second alternative of Corollary 5.3 holds and work towards proving the second alternative of the theorem. In particular, there exists a greatest position \( k \) in \( \pi \) where a subsequence isomorphic to a permutation in \( C \) can begin, and this position occurs in the final (infinite) sum component \( \pi_z \) of \( \pi \).

Next we prepare the ground for two arguments that occur later in the proof and which depend upon the indecomposability of \( \pi_z \). Suppose that \( r \) is any position in \( \pi_z \). We define a pair of sequences \( U(r) = u_1 u_2 \cdots \) and \( V(r) = v_1 v_2 \cdots \) by the following rules:

1. \( v_i \) is the position among the terms of \( \pi \) up to and including position \( u_{i-1} \) (when \( i = 1 \) take \( u_0 = r \)) where the greatest element occurs:
   \[
   \pi(v_i) = \max\{\pi(k) \mid k \leq u_{i-1}\}.
   \]

2. \( u_i \) is the rightmost position in \( \pi \) where a term not exceeding \( \pi(v_i) \) occurs:
   \[
   u_i = \max\{k \mid \pi(k) \leq \pi(v_i)\}.
   \]

Figure 2 depicts these points and the next lemma assures us that the figure accurately represents the relative positions of the marked points.

**Lemma 3.5** The relative positions and sizes of the terms \( \pi(u_i) \) and \( \pi(v_j) \) are described by the following inequalities:

\[
\begin{align*}
  v_1 &< v_2 < u_1 < v_3 < u_2 < v_4 < u_3 < \cdots \\
  \pi(u_1) &< \pi(v_1) < \pi(u_2) < \pi(v_2) < \pi(u_3) < \pi(v_3) < \cdots
\end{align*}
\]

**Proof:**

(I) From the definition of \( v_i \) we have \( v_i \leq u_{i-1} \), and from the definition of \( u_i \) we have and \( \pi(v_i) \geq \pi(u_i) \). Note that we cannot have \( u_i = u_{i-1} \), because then every term of \( \pi \) to the left of this position would be less than or equal to \( \pi(v_i) \), and every term to the right would be greater than \( \pi(v_i) \), contradicting the assumption that \( \pi(v_i) \) belongs to the final component of \( \pi \). Hence we have \( v_i \leq u_{i-1} < u_i \) and \( \pi(v_i) > \pi(u_i) \).

(II) By the definition of \( v_{i+1} \), we have \( v_{i+1} \leq u_i \) and \( \pi(v_{i+1}) \geq \pi(v_i) \). We cannot have \( v_{i+1} < v_i \), because \( \pi(v_i) \) is the maximal value of \( \pi \) on the interval \([1, u_{i-1}]\). Also, we cannot have \( v_{i+1} = v_i \), because that would imply \( u_{i+1} = u_i \), which is proved impossible as in (I). Finally, we cannot have \( v_{i+1} = u_i \) because \( \pi(u_i) < \pi(v_i) \) by (I). We conclude that \( v_i < v_{i+1} < u_i \) and \( \pi(v_i) < \pi(u_{i+1}) \).
Figure 2: The terms of $\pi$ as mapped out by $\pi(u_i)$ and $\pi(v_i)$. All terms lie in the shaded boxes.

(III) As in (I), we have $u_{i+1} > u_i$ and $\pi(u_{i+1}) < \pi(v_{i+1})$. Moreover, $u_{i+1} > u_i$ immediately implies that $\pi(u_{i+1}) > \pi(v_i)$.

(IV) As in (II), we have $v_{i+2} < u_{i+1}$ and $\pi(v_{i+2}) > \pi(v_{i+1})$. Moreover, $v_{i+2} > u_i$ for otherwise we would have $\pi(v_{i+2}) \leq \pi(v_{i+1})$.

Summarising (I)–(IV), we have $v_i < v_{i+1} < u_i < v_{i+2} < u_{i+1}$ and $\pi(u_i) < \pi(v_i) < \pi(u_{i+1}) < \pi(v_{i+1}) < \pi(v_{i+2})$ for every $i = 1, 2, \ldots$, which is enough to prove the lemma.

Our first use of the sequences $U(r)$ and $V(r)$ and the above lemma occurs immediately. We have seen (Lemma 3.2) that there is a rightmost position in $\pi$ where subsequences order isomorphic to permutations in $C$ can begin. Now we prove that there is a rightmost position by which they have all ended.

Lemma 3.6 There exists a position $\ell$ of $\pi$ such that no subsequence of $\pi$ that is order isomorphic to an element of $C$ terminates after position $\ell$.

PROOF: Consider the sequences $U(k), V(k)$ and refer to Figure 2 with $r = k$, in particular to the edge-connected strip of boxes that begins with the box $B_1$ bounded by $\pi(v_1)$ and $\pi(k)$. Let $S$ be a subsequence of $\pi$ isomorphic to a permutation $\gamma \in C$. By definition of $k$, $S$ cannot start to the right of $\pi(k)$. In fact, since $\gamma$ is indecomposable, $S$ must start in $B_1$, and the terms of $S$ must lie in a contiguous segment of boxes. Therefore, as $|S| \leq b$, $S$ cannot extend beyond position $u_b/2$.

In view of this lemma we may define $\ell$ as the last position of $\pi$ that is part of a subsequence isomorphic to an element of $C$. Now we define the sequences $U(\ell), V(\ell)$ (and, re-using notation, call them $u_1, u_2, \ldots$ and $v_1, v_2, \ldots$).

The defining property of $\ell$ implies that $\pi(1), \ldots, \pi(\ell)$ is the only subsequence of $\pi$ with this order isomorphism type. For any subsequence of $\pi$ order isomorphic to
\(\pi(1), \ldots, \pi(\ell)\) has a final element that is part of a subsequence order isomorphic to an element of \(C\). Therefore this final element cannot occur after position \(\ell\) within \(\pi\) and so it must be \(\pi(1), \ldots, \pi(\ell)\) itself. Notice also, again from the definition of \(\ell\), that the permutation order isomorphic to \(\pi(1), \ldots, \pi(\ell)\) is the longest permutation in \(X\) whose last element is the terminating element of a subsequence order isomorphic to an element of \(C\); as such, this permutation depends on \(X\) and not on \(\pi\). In the next lemma we prove that a number of other initial segments of \(\pi\) are unique of their isomorphism type, and depend on \(X\) rather than on \(\pi\).

**Lemma 3.7** For each \(i = 1, 2, \ldots\) the sequence \(\pi(1), \ldots, \pi(u_i)\) is the unique subsequence of that order isomorphism type. Its corresponding permutation \(\beta = \beta(1), \ldots, \beta(u_i)\) is the longest permutation in \(X\) satisfying the following two properties:

1. \(\beta(1), \ldots, \beta(u_i - 1)\) is isomorphic to \(\pi(1), \ldots, \pi(u_i - 1)\) (where \(u_0 = l\));
2. \(\beta(u_i) \leq \beta(v_t)\).

As such, \(\beta\) depends on \(X\) only, and not on \(\pi\).

**Proof:** We prove the lemma by induction, anchoring it at \(u_0 = l\). Assume that the statements are true for some \(i \geq 1\), and consider any subsequence \(\pi(s_1), \ldots, \pi(s_{u_i+1})\) order isomorphic to \(\pi(1), \ldots, \pi(u_i+1)\). By the inductive hypothesis we must have \(s_j = j\) for \(j = 1, \ldots, u_i\). But then, since \(\pi(u_i+1)\) is the rightmost term of \(\pi\) smaller than \(\pi(v_{i+1})\), and since there are \(u_{i+1} - u_i - 1\) terms between \(\pi(u_i)\) and \(\pi(u_{i+1})\), it follows that \(s_j = j\) for \(j = u_i + 1, \ldots, u_{i+1}\) as well.

Clearly, the permutation \(\beta\) satisfies properties (1) and (2), by virtue of being isomorphic to \(\pi(1), \ldots, \pi(u_{i+1})\). Suppose that \(\gamma = \gamma(1), \ldots, \gamma(m)\) is any permutation satisfying these conditions. Consider an embedding \(\pi(t_1), \ldots, \pi(t_m)\) of \(\gamma\) in \(\pi\). As above, we must have \(t_j = j\) for \(j = 1, \ldots, u_i\). And again, \(\pi(u_{i+1})\) being the rightmost term of \(\pi\) smaller than \(\pi(v_{i+1})\), we have that \(t_m \leq u_{i+1}\). But this, in turn, implies that \(|\gamma| = m \leq t_m \leq u_{i+1} = |\beta|\). This proves that \(\beta\) is indeed the longest permutation of \(X\) satisfying (1) and (2). The last statement of the lemma is now straightforward.

At this point we can prove the uniqueness of \(\pi\): it is the limit of its initial segments \(\pi(1) \cdots \pi(u_i)\) and these depend on \(X\) alone.

For future use we record the following result, the proof of which is analogous to the proof of Lemma 3.7.

**Lemma 3.8** For each \(i = 2, 3, \ldots\) the subsequence consisting of all terms of \(\pi\) not exceeding \(\pi(v_i)\) is unique of its order isomorphism type. Its corresponding permutation \(\beta = \beta(1), \ldots, \beta(v_i)\) is the longest permutation in \(X\) satisfying the following two properties:
(1) \( \beta(1), \ldots, \beta(u_{i-1}) \) is isomorphic to \( \pi(1), \ldots, \pi(u_{i-1}) \);

(2) \( \beta(v_i) \) is its largest term.

As such, \( \beta \) depends on \( X \) only, and not on \( \pi \).

The subsequences whose embeddings are unique in the previous two lemmas are those all of whose terms are taken from an initial contiguous strip of blocks in Figure 2 (with \( r = t \)). For convenience we let \( \sigma(i) \) be the permutation isomorphic to the first type of subsequence (Lemma 3.7), and \( \sigma'(i) \) be the permutation isomorphic to the second type (Lemma 3.8).

**Lemma 3.9** \( u_{i+1} - u_i \leq 2(b - 1)^2 \)

**Proof:** Of course \( u_{i+1} - u_i \) is the number of terms of \( \pi(u_i + 1) \cdots \pi(u_{i+1}) \).

We divide these terms into two sets

\[
L = \{ j | u_i < j \leq u_{i+1} \text{ and } \pi(j) < \pi(v_{i+1}) \}
\]

and

\[
U = \{ j | u_i < j \leq u_{i+1} \text{ and } \pi(j) > \pi(v_{i+1}) \}
\]

and we shall show that both \( |L| \) and \( |U| \) are at most \( (b - 1)^2 \). Each bound is proved in the same way and we give the details for \( |L| \) only. Figure 3 depicts the locations of \( L \) and \( U \) within \( \pi \).

Consider a maximal increasing subsequence \( \pi(j_1)\pi(j_2) \cdots \pi(j_m) \) of \( \pi \) such that all \( j_i \in L \). Using this we form another subsequence of \( \pi \) whose terms are the following:

1. all terms not exceeding \( \pi(v_i) \), (a subsequence order isomorphic to \( \sigma'(i) \))
2. the term \( \pi(v_{i+1}) \)
3. all the terms \( \pi(j_1)\pi(j_2) \cdots \pi(j_m) \)

The permutation which is order isomorphic to this subsequence is, of course, a member of \( X \) and we write it as \( \lambda n \rho \theta \) where \( n \) corresponds to the term \( \pi(v_{i+1}) \), \( \lambda \rho \) corresponds to \( \sigma'(i) \), and \( \theta = n - m, n - m + 1, \ldots, n - 1 \) corresponds to \( \pi(j_1)\pi(j_2) \cdots \pi(j_m) \).

Now consider another permutation almost the same as this except that \( \theta \) contains one more term, and \( n \) is replaced by \( n + 1 \). It has the form \( \lambda, n + 1, \rho \theta' \) with \( \theta' = n - m, n - m + 1, \ldots, n - 1, n \). This permutation does not belong to \( X \). To see this, assume that some subsequence of \( \pi \) is order isomorphic to it. In the correspondence between the permutation and the subsequence, \( \lambda \rho \) (which is order isomorphic to \( \sigma'(i) \)) must be mapped to the subsequence of terms not exceeding \( \pi(v_i) \), by Lemma 3.8, and \( n + 1 \) must be mapped to one of the terms.
of \( \pi \) in the range of positions \( u_{i-1} + 1 \) to \( u_i \). This forces \( \theta' \) to be mapped into \( L \) as these are the only positions of \( \pi \) to the right of \( u_i \) and smaller than \( \pi(v_{i+1}) \). However, this contradicts that \( L \) contains no increasing sequence of length \( m+1 \).

It follows that \( \lambda, n + 1, \rho \theta' \) must involve a basis element of \( X \). A particular embedding of a basis element must contain all the terms of \( \theta' \) for otherwise this basis element would be embedded in \( \lambda \rho \theta \) which is impossible. In particular we can deduce that \( m + 1 \leq b \).

Exactly the same argument can be carried out for maximal decreasing subsequences. Thus the sequence \( \pi(L) \) contains no increasing or decreasing subsequence of length more than \( b - 1 \) and, by the well known result of Erdős and Szekeres (see [6]), we conclude that \( |L| \leq (b - 1)^2 \).

The proof that \( |U| \leq (b - 1)^2 \) is similar but it uses \( \pi(u_{i+1}) \) and \( \sigma(i) \) instead of \( \pi(v_{i+1}) \) and \( \sigma'(i) \).

We now define an encoding of permutations of \( X \). If \( \xi = x_1x_2 \cdots x_n \in X \) then we encode it as \( E(\xi) = e_1e_2 \cdots e_n \) where

\[
e_k = |\{i \mid 1 \leq i \leq k \text{ and } x_i \geq x_k\}|
\]

If a term of \( \pi \) lies in the final component beyond position \( u_2 \) then there are, by Lemma 3.9, at most \( 4(b - 1)^2 \) preceding terms greater than it. On the other hand, if it lies in one of the finite components or in the final component and not beyond position \( u_2 \) then, obviously, there will again only be a bounded number of preceding greater terms. Since permutations of \( X \) are order isomorphic to subsequences of \( \pi \) and \( \pi \) is determined by \( X \) there is an upper bound depending on \( X \) alone for each of the code symbols \( e_k \). Thus we may consider \( E(X) \) as a language over some finite alphabet \( A = \{1, \ldots, m\} \).

![Figure 3: \( \pi \) mapped out by \( u_i \) and \( v_i \). None of the boxes marked \( L \) or \( U \) contains a monotonic increasing or decreasing subsequence of length \( b \). Thus the sizes of these boxes is bounded.](image)
The encoding has the property that, if $\gamma = \delta \epsilon$ is a permutation and $\bar{\delta}$ is the permutation order isomorphic to the initial segment $\delta$, then $E(\bar{\delta})$ is an initial segment of $E(\gamma)$.

Furthermore this encoding (in which every element of a permutation is encoded by the number of its higher predecessors) is closely related to the encoding studied in [1] (in which every element was encoded by its number of lower successors). In fact, if $F(\xi)$ denotes the latter encoding and $\bar{\xi}$ is the permutation obtained from $\xi$ by replacing each element $x_i$ by $|\xi| - x_i + 1$ and then reversing it, then $F(\bar{\xi})$ is the reverse of $E(\xi)$. It therefore follows from Theorem 2 of [1] that

**Lemma 3.10** $E(X)$ is a regular set.

We can now confirm one of the claims we made when stating Theorem 3.1: from the results of [1] the ordinary generating function of the sequence $(g_n)$, where $g_n$ is the number of permutations of length $n$, is a rational function. But to show that $\pi$ is eventually periodic and thus complete the proof of the theorem we need to study a deterministic finite automaton that accepts $E(X)$. We denote this automaton by $M = (\Sigma, A, s_0, \tau, T)$ (the notation specifies, respectively, the set of states, the alphabet, the initial state, the transition function, and the set of final states).

**Lemma 3.11** $\{E(\sigma(i)) \mid i = 1, 2, \ldots \}$ contains the set $\{\alpha\beta^j \mid j = 0, 1, 2, \ldots \}$ defined by the regular expression $\alpha\beta^*$ for some non-empty words $\alpha, \beta \in A^*$.

**Proof:** We shall consider the sequence of states $t_i = \tau(s_0, E(\sigma(i))), i = 1, 2, \ldots$ and aim to show that it is periodic. By definition and by Lemma 3.7

\[ \sigma(i + 1) = \theta\phi \]

where

(a) $\theta$ is a sequence order isomorphic to $\sigma(i)$

(b) $\phi = a_1a_2 \cdots a_n$ satisfies $a_n < \max(\theta)$ and $\theta\phi \in X$

(c) $\phi$ is maximal with these properties.

We shall express these conditions in terms of the automaton $M$. From (a), (b) and the definition of $E$ we have

\[ E(\sigma(i + 1)) = E(\sigma(i))b_1b_2 \cdots b_n \]

where $w = b_1b_2 \cdots b_n$ is a word in the alphabet $A$ and $\tau(t_i, w) = t_{i+1}$.

By definition, $b_j$ is the number of terms of $\theta\phi$ up to and including $a_j$ that exceed or equal $a_j$. To capture the condition $a_n < \max(\theta)$ we need to define
another sequence \(c_0c_1c_2 \cdots c_n\) where \(c_0 = 0\) and \(c_j\) is the number of terms up to and including \(a_j\) that exceed \(\max(\theta)\); of course, all such terms are among \(a_1, a_2, \ldots, a_n\).

If \(a_j < \max(\theta)\) then the terms enumerated by \(b_j\) include \(\max(\theta)\), \(a_j\) and the \(c_{j-1}\) terms above \(\max(\theta)\); hence \(b_j > c_{j-1} + 1\). However, if \(a_j > \max(\theta)\) then each of the \(b_j\) terms that exceed or equal \(a_j\) is one of the terms that exceeds \(\max(\theta)\); hence \(b_j \leq c_{j-1} + 1\). Furthermore, in the former case \(c_j = c_{j-1}\) and in the latter case \(c_j = c_{j-1} + 1\). Thus \(c_1c_2 \cdots c_n\) is determined uniquely by \(b_1b_2 \cdots b_n\), and \(a_n < \max(\theta)\) if and only if \(b_n > c_n\).

Putting all this together \(t_{i+1}\) is the unique state of \(\mathcal{M}\) for which there exists a word \(w = b_1b_2 \cdots b_n\) in the alphabet \(A\) with the following properties:

1. \(\tau(t_i, w) = t_{i+1}\);
2. if the sequence \((c_0, c_1, \ldots, c_n)\) is defined by \(c_0 = 0\) and, for \(j > 0\),
   \[
   c_j = \begin{cases} 
   c_{j-1} + 1 & \text{if } b_j \leq c_{j-1} + 1, \\
   c_{j-1} & \text{if } b_j > c_{j-1} + 1
   \end{cases}
   \]
   then \(b_n > c_n\);
3. \(w\) has maximal length among all words satisfying these two conditions.

But now note that the three conditions depend only on the \(t_i\) and the automaton \(\mathcal{M}\) and not on \(E(\sigma(i))\). Therefore the sequence \(t_1, t_2, \ldots\) is ultimately periodic. So, for some \(P > 0\) and \(N\) we have \(t_j = t_{j+P}\) for all \(j \geq N\).

Let \(\alpha = E(\sigma(N))\) and let \(\beta\) be the unique word such that \(E(\sigma(N + P)) = \alpha\beta\). Then \(E(\sigma(N+hP)) = \alpha^h\beta\) and \(\tau(s_0, \alpha^h\beta) = t_N\) for all \(h \geq 0\). This proves that \(\alpha^* \subseteq \{E(\sigma(i)) \mid i = 1, 2, \ldots\}\).

We can now complete the proof of Theorem 4.1. In the notation of the previous lemma, let \(|\alpha| = m\) and \(|\beta| = n\). Consider the encoding of \(\pi\) itself: \(E(\pi) = e_1e_2 \cdots\). This is just the limit of its prefixes \(E(\sigma(1)), E(\sigma(2)), \ldots\). It is also the limit of \(E(\sigma(N)), E(\sigma(N + P)), E(\sigma(N + 2P)), \ldots\). Hence, by Lemma 4.11 \(E(\pi)\) is ultimately periodic with \(e_{j+P} = e_j\) for all \(j \geq N\).

Consider an arbitrary \(\pi(j)\) with \(j \geq N\). We have \(\pi(j) = l_j + r_j + 1\) where
\[
l_j = |\{i \mid i \leq j \text{ and } \pi(i) < \pi(j)\}|
\]
and
\[
r_j = |\{i \mid i > j \text{ and } \pi(i) < \pi(j)\}|
\]
Obviously, \(l_j = j - e_j\). The number \(r_j\) can be obtained from \(E(\pi)\) as follows. Define two sequences \(\nu^{(j)} = (n_0, n_1, \ldots)\) and \(\theta^{(j)} = (h_0, h_1, \ldots)\) by \(n_0 = 0\) and \(h_0 = e_j\) and
\[
n_{i+1} = \begin{cases} 
   n_i + 1 & \text{if } e_{j+i+1} > h_i \\
   n_i & \text{otherwise}
   \end{cases}
\]

15
and
\[ h_{i+1} = \begin{cases} h_i & \text{if } e_{j+i+1} > h_i \\ h_i + 1 & \text{otherwise} \end{cases} \]

An easy inductive argument shows that \( n_i \) is equal to the number of terms from \( \pi(j+1), \ldots, \pi(j+i) \) which are smaller than \( \pi(j) \), while \( h_i - e_j \) is the number of terms from the same set which are greater than \( \pi(j) \). In particular, \( \nu^{(j)} \) eventually becomes constant with value \( r_j \).

Finally, note that \( \nu^{(j)} \) depends only on \( e_1 e_2 \cdots e_j e_{j+1} \cdots \) and not on \( e_1 e_2 \cdots e_{j-1} \). Hence \( \nu^{(j)} = \nu^{(j+P)} \) and \( r_j = r_{j+P} \). Therefore
\[
\pi(j + P) = l_j + P + r_{j+P} + 1 \\
= j + P - e_{j+P} + r_{j+P} + 1 \\
= P + j - e_j + r_j + 1 \\
= P + l_j + r_j + 1 \\
= P + \pi(j)
\]
as required.

## 4 Natural classes with infinite bases

Any natural class class that is not of the form stipulated by the conclusion of Theorem 3.1 is, of course, not finitely based. An example of such a class is \( Y = \text{Sub}(\pi) \) where
\[
\pi = 3 \ 2 \ 5 \ 1 \ [7, 8] \ 4 \ [10, 12] \ 6 \ [14, 17] \ 9 \ [19, 23] \ 13 \ [25, 30] \ 18 \ [32, 38] \ 24 \ldots
\]

In this example \([a, b]\) stands for the segment \([a, a+1, \ldots, b]\). It is clear by inspection that \( \pi \) is not periodic and so, by the uniqueness conclusion of Theorem 3.1 \( Y \) is not of periodic type. We argue that it is not of the form \( \text{Sub}(\gamma) \oplus S \) where \( S \) is sum-complete. Suppose it were of this form. Consider the initial segments of \( \pi \) ending with one of \( 1, 4, 6, 9, \ldots \) respectively. These all define permutations \( \xi_1, \xi_2, \xi_3, \xi_4 \ldots \) of \( Y \). Every \( \xi_i \) is indecomposable and has a unique embedding in \( \pi \). From the indecomposability those \( \xi_i \) of length greater than \( \gamma \) must be order isomorphic to permutations of \( S \); but, if \( \xi_i \in S \), so also is \( \xi_i \oplus \xi_i \) which contradicts that it is uniquely embeddable in \( \pi \).

It would perhaps be tempting to suppose that when \( \pi \) is periodic, the closed class \( \text{Sub}(\pi) \) is always finitely based. This, however, is not the case, as our final example shows.

Let \( X = \text{Sub}(\pi) \), where
\[
\pi = 2 \ 3 \ 5 \ 1 \ 7 \ 8 \ 4 \ 10 \ 6 \ 12 \ 13 \ 9 \ 15 \ 11 \ldots
\]

Essentially, \( \pi \) is an increasing oscillating sequence with every other left maximal term replaced with an increasing pair (the underlinings are intended to highlight
Call these increasing pairs twins, and note that they are the only pairs of terms of \( \pi \) occurring in successive positions and having successive values.

We claim that each of the following permutations belongs to the basis of \( X \):

\[
\beta_1 = \begin{array}{cccccc}
2 & 3 & 4 & 5 & 1 \\
\end{array}
\]
\[
\beta_2 = \begin{array}{cccccccc}
2 & 3 & 5 & 1 & 7 & 4 & 8 & 9 & 6 \\
\end{array}
\]
\[
\vdots
\]
\[
\beta_n = \begin{array}{cccccccccccc}
2 & 3 & 5 & 1 & 7 & 4 & 8 & 9 & \cdots & 4n - 3 & 4n - 6 & 4n - 1 & 4n - 4 & 4n + 1 & 4n - 2 \\
\end{array}
\]
\[
\vdots
\]

The permutation \( \beta_n \) is obtained from an oscillating sequence with an even number of left maximal terms by replacing the first and last of these terms by increasing pairs (see Figure 4). To show that \( \beta_n \not\in X \) we can argue as follows. Write \( \pi \) as

\[
\pi = U_0 U_1 l_1 U_2 l_2 U_3 l_3 \ldots,
\]

where \( U_0, U_2, U_4, \ldots \) are the twins, \( U_1, U_3, U_5, \ldots \) are the remaining (unexpanded) left maxima, and \( l_1, l_2, l_3, \ldots \) are the remaining terms. Suppose \( \beta_n \) embeds into \( \pi \). The two twins of \( \beta_n \) must correspond to two twins, say \( U_{2p} \) and \( U_{2q} \), of \( \pi \). Since \( \beta_n \) is indecomposable, the remaining left maxima \( 5, 7, 9, \ldots \) of \( \beta_n \) must map into \( U_{2p+1}, U_{2p+2}, U_{2p+3}, \ldots \) respectively. The number of left maxima between the two twins of \( \beta_n \) is even, while the number of segments \( U_{2p+1}, \ldots, U_{2q-1} \) is odd, a contradiction.

To complete the proof that \( \beta_n \) is a basis permutation of \( X \), we need to demonstrate that \( \beta_n \setminus \{ \beta_n(j) \} \), the permutation obtained by removing the \( j \)th term from \( \beta_n \), belongs to \( X \) for every \( j = 1, \ldots, 4n + 1 \). If \( j \not\in \{ 2, 3, 4n, 4n + 1 \} \) the resulting permutation is decomposable, and can be embedded into \( \pi \) by embedding each of its components and keeping them sufficiently apart. If \( j \) is one of \( 2, 3, 4n \) or \( 4n + 1 \) then one of the twins of \( \beta_n \) becomes a singleton. Suppose, for the sake of argument, that \( j = 4n + 1 \) (the other cases are treated analogously). Then we can embed \( \beta_n \setminus \{ \beta_n(4n + 1) \} \) by mapping 2 and 3 onto \( U_0 \), all the other left maxima of \( \beta_n \) into \( U_1, U_2, \ldots \) respectively, and the remaining terms
into \(l_1, l_2, \ldots\) respectively. Note that the parity problem which prevented us from embedding \(\beta_n\) into \(\pi\) does not arise here, because the second twin of \(\beta_n\) has become a singleton in \(\beta_n \setminus \{\beta_n(4n+1)\}\), and can therefore be mapped onto the singleton \(U_{2n-1}\).
