SLUA: A Super Lightweight Unsupervised Word Alignment Model via Cross-Lingual Contrastive Learning

†Peking University ‡The University of Sydney

Abstract

Word alignment is essential for the downstream cross-lingual language understanding and generation tasks. Recently, the performance of the neural word alignment models [Zenkel et al., 2020; Garg et al., 2019; Ding et al., 2019] has exceeded that of statistical models. However, they heavily rely on sophisticated translation models. In this study, we propose a Super Lightweight Unsupervised word Alignment (SLUA) model, in which a bidirectional symmetric attention trained with a contrastive learning objective is introduced, and an agreement loss is employed to bind the attention maps, such that the alignments follow mirror-like symmetry hypothesis. Experimental results on several public benchmarks demonstrate that our model achieves competitive, if not better, performance compared to the state of the art in word alignment while significantly reducing the training and decoding time on average. Further ablation analysis and case studies show the superiority of our proposed SLUA. Notably, we recognize our model as a pioneer attempt to unify bilingual word embedding and word alignments. Encouragingly, our approach achieves $16.4 \times$ speedup against GIZA++, and $50 \times$ parameter compression compared with the Transformer-based alignment methods. We will release our code to facilitate the community.

1 Introduction

Word alignment, aiming to find the word-level correspondence between a pair of parallel sentences, is a core component of the statistical machine translation (SMT, [Brown et al., 1993]). It also has benefited several downstream tasks, e.g., computer-aided translation [Dagan et al., 1993], semantic role labeling [Kozhevnikov and Titov, 2013], cross-lingual dataset creation [Yarowsky et al., 2001] and cross-lingual modeling [Ding et al., 2020].

Recently, in the era of neural machine translation (NMT, [Bahdanau et al., 2015; Vaswani et al., 2017]), the attention mechanism plays the role of the alignment model in translation system. Unfortunately, [Koehn and Knowles, 2017] show that attention mechanism may in fact dramatically diverge with word alignment. The works of [Li et al., 2019; Ghader and Monz, 2017] also confirm this finding.

Although there are some studies attempt to mitigate this problem, most of them are rely on a sophisticated translation architecture [Zenkel et al., 2020; Garg et al., 2019]. These methods are trained with a translation objective, which computes the probability of each target token conditioned on source tokens and previous target tokens. This will bring tremendous parameters and noisy alignments. Most recent work avoids the noisy alignment of translation models but employed too much expensive human-annotated alignments [Stengel-Eskin et al., 2019]. Given these disadvantages, simple statistical alignment tools, e.g., FastAlign [Dyer et al., 2013] and GIZA++ [Och and Ney, 2003]$^1$, are still the most representative solutions due to its efficiency and unsupervised fashion. We argue that the word alignment task, intuitively, is much simpler than translation, and thus should be performed before translation rather than inducing alignment matrix with heavy neural machine translation models. For example, the IBM word alignment model, e.g., FastAlign, is the prerequisite of SMT. However, related research about super lightweight neural word alignment without NMT is currently very scarce.

Inspired by cross-lingual word embeddings (CLWEs) [Luong et al., 2015], we propose to implement a super lightweight unsupervised word alignment model in §3, named SLUA, which encourages the embeddings between

---

$^1$GIZA++ employs the IBM Model 4 as default setting.
aligned words to be closer. We also provide the theoretical justification from mutual information perspective for our proposed contrastive learning objective in §3.4, demonstrating its reasonableness. Figure 1 shows an English sentence, and its corresponding Chinese and Japanese sentences, and their word alignments. The links indicate the correspondence between English⇔Chinese and English⇔Japanese words. If the Chinese word “举行” can be aligned to English word “held”, the reverse mapping should also hold. Specifically, a bidirectional attention mechanism with contrastive estimation is proposed to capture the alignment between parallel sentences. In addition, we employ an agreement loss to constrain the attention maps such that the alignments follow symmetry hypothesis [Liang et al., 2006].

Our contributions can be summarized as follows:

- We propose a super lightweight unsupervised alignment model (SLUA), even merely updating the embedding matrices, achieves better alignment quality on several public benchmark datasets compare to baseline models while preserving comparable training efficiency with FastAlign.

- To boost the performance of SLUA, we design a theoretically and empirically proved bidirectional symmetric attention with contrastive learning objective for word alignment task, in which we introduce extra objective to follow the mirror-like symmetry hypothesis.

- Further analysis show that the by-product of our model in training phase has the ability to learn bilingual word representations, which endows the possibility to unify these two tasks in the future.

2 Related Work

Word alignment studies can be divided into two classes:

Statistical Models Statistical alignment models directly build on the lexical translation models of [Brown et al., 1993], also known as IBM models. The most popular implementation of this statistical alignment model is FastAlign [Dyer et al., 2013] and GIZA++ [Och and Ney, 2000; Och and Ney, 2003]. For optimal performance, the training pipeline of GIZA++ relies on multiple iterations of IBM Model 1, Model 3, Model 4 and the HMM alignment model [Vogel et al., 1996]. Initialized with parameters from previous models, each subsequent model adds more assumptions about word alignments. Model 2 introduces non-uniform distortion, and Model 3 introduces fertility. Model 4 and the HMM alignment model introduce relative distortion, where the likelihood of the position of each alignment link is conditioned on the position of the previous alignment link. FastAlign [Dyer et al., 2013], which is based on a reparametrization of IBM Model 2, is almost the existing fastest word aligner, while keeping the quality of alignment.

In contrast to GIZA++, our SLUA model achieves nearly 15× speedup during training, while achieving the comparable performance. Encouragingly, our model is at least 1.5× faster to train than FastAlign and consistently outperforms it.

Neural Models Most neural alignment approaches in the literature, such as [Alkhouli et al., 2018], rely on alignments generated by statistical systems that are used as supervision for training the neural systems. These approaches tend to learn to copy the alignment errors from the supervising statistical models. [Zenkel et al., 2019] use attention to extract alignments from a dedicated alignment layer of a neural model without using any output from a statistical aligner, but fail to match the quality of GIZA++. [Garg et al., 2019] represents the current state of the art in word alignment, outperforming GIZA++ by training a single model that is able to both translate and align. This model is supervised with a guided alignment loss, and existing word alignments must be provided to the model during training. [Garg et al., 2019] can produce alignments using an end-to-end neural training pipeline guided by attention activations, but this approach underperforms GIZA++. The performance of GIZA++ is only surpassed by training the guided alignment loss using GIZA++ output. [Stengel-Eskin et al., 2019] introduce a discriminative neural alignment model that uses a dot-product-based distance measure between learned source and target representation to predict if a given source-target pair should be aligned. Alignment decisions condition on the neighboring decisions using convolution. The model is trained using gold alignments. [Zenkel et al., 2020] uses guided alignment training, but with large number of modules and parameters, they can surpass the alignment quality of GIZA++.

They either use translation models for alignment task, which introduces a extremely huge number of parameters (compare to ours), making the training and deployment of the model cumbersome. Or they train the model with the alignment supervision, however, these alignment data is scarce in practice especially for low resource languages. These settings make above approaches less versatile.

Instead, our approach is fully unsupervised at word level, that is, it does not require gold alignments generated by human annotators during training. Moreover, our model achieves comparable performance and is at least 50 times smaller than them, i.e., #Parameters: 4M (ours) vs. 200M (above).

3 Our Approach

Our model trains in an unsupervised fashion, where the word level alignments are not provided. Therefore, we need to leverage sentence-level supervision of the parallel corpus. To achieve this, we introduce negative sampling strategy with contrastive learning to fully exploit the corpus. Besides, inspired by the concept of cross-lingual word embedding, we design the model under the following assumption: If a target token can be aligned to a source token, then the dot product of their embedding vectors should be large. Figure-2 shows the schema of our approach SLUA.

3.1 Sentence Representation

For a given source-target sentence pair $(s, t)$, $s_i, t_j \in \mathbb{R}^d$ represent the $i$-th and $j$-th word embeddings for the source and target sentences, respectively. In order to capture the contextualized information of each word, we perform mean pooling
operation with the representations of its surrounding words. Padding operation is used to ensure the sequence length. As a result, the final representation of each word can be calculated by element-wisely adding the mean pooling embedding and its original embedding:

\[ x_i = \text{MEANPOOL}([s_i]^{\text{win}}) + s_i, \]

where \( \text{win} \) is the pooling window size. We can therefore derive the sentence level representations \( [x_1, x_2, ..., x_{|s|}], [y_1, y_2, ..., y_{|t|}] \) for s and t.

### 3.2 Bidirectional Symmetric Attention

Bidirectional symmetric attention is the basic component of our proposed model. The aim of this module is to generate the source-to-target (aka. s2t) and target-to-source (aka. t2s) soft attention maps. The details of the attention mechanism: given a source side word representation \( x_i \) as query \( q_i \in \mathbb{R}^d \) and pack all the target tokens together into a matrix \( V_t \in \mathbb{R}^{t \times d} \).

The attention context can be calculated as:

\[
\text{ATTENTION}(q_i, V_t, V_s) = (a^s_i \cdot V_s)^\top, \tag{2}
\]

where the vector \( a^s_i \in \mathbb{R}^{1 \times |t|} \) represents the attention probabilities for \( q_i \) in source sentence over all the target tokens, in which each element signifies the relevance to the query, and can be derived from:

\[
a^s_i = \text{SOFTMAX}(V_t \cdot q_i)^\top. \tag{3}
\]

For simplicity, we denote the attention context of \( q_i \) in the target side as \( \text{ATT}(q_i) \). s2t attention map \( A_{s,t} \in \mathbb{R}^{|s| \times |t|} \) is constructed by stacking the probability vectors \( a^s_i \) corresponding to all the source tokens.

Reversely, we can obtain t2s attention map \( A_{t,s} \) in a symmetric way. Then, these two attention matrices \( A_{s,t} \) and \( A_{t,s} \) will be used to decode alignment links. Take s2t for example, given a target token, the source token with the highest attention weight is viewed as the aligned word.

### 3.3 Agreement Mechanism

Intuitively, the two attention matrices \( A_{s,t} \) and \( A_{t,s}^\top \) should be very close. However, the attention mechanism suffers from symmetry error in different direction [Koehn and Knowles, 2017].

To bridge this discrepancy, we introduce agreement mechanism [Liang et al., 2006], acting like a mirror that precisely reflects the matching degree between \( A_{s,t} \) and \( A_{t,s} \), which is also empirically confirmed in machine translation [Levinboim et al., 2015]. In particular, we use an agreement loss to bind above two matrices:

\[
\text{Loss}_{\text{disagree}} = \sum_i \sum_j (A^t_{i,j} - A^{\top}_{j,i})^2. \tag{4}
\]

In §4.6, we empirically show this agreement can be complementary to the bidirectional symmetric constraint, demonstrating the effectiveness of this component.

### 3.4 Training Objective and Theoretical Justification

Suppose that \((q_i, \text{ATT}(q_i))\) is a pair of s2t word representation and corresponding attention context sampled from the joint distribution \( p_i(q, \text{ATT}(q)) \) (hereinafter we call it a positive pair), the primary objective of the s2 training is to maximize the alignment degree between the elements within a positive pair. Thus, we first define an alignment function by using the sigmoid inner product as:

\[
\text{ALIGN}(q, \text{ATT}(q)) = \sigma(\langle q, \text{ATT}(q) \rangle), \tag{5}
\]

where \( \sigma(\cdot) \) denotes the sigmoid function and \( \langle \cdot, \cdot \rangle \) is the inner product operation. However, merely optimizing the alignment of positive pairs ignores important positive-negative relation knowledge [Mikolov et al., 2013].

To make the training process more informative, we re-form the overall objective in the contrastive learning man-
ner [Saunshi et al., 2019; Oord et al., 2018] with Noise Contrastive Estimation (NCE) loss [Mikolov et al., 2013]. Specifically, we first sample \( k \) negative word representations \( q_j \) from the margin \( p_h(q) \). Then, we can formulate the overall NCE objective as following:

\[
\text{Loss}_{s \rightarrow t} = - \mathbb{E}_{\{\text{att}_t(q), q, j\}} \left[ \log \frac{\text{ALIGN}(q_i, \text{att}_t(q_i))}{\text{ALIGN}(q_i, \text{att}_t(q_i)) + \sum_{j=1}^{k} \text{ALIGN}(q_j, \text{att}_t(q_j))} \right],
\]

(6)

It is evident that the objective in Eq. (6) explicitly encourages the alignment of positive pair \( \{q_i, \text{att}_t(q_i)\} \) while simultaneously separates the negative pairs \( \{q_j, \text{att}_t(q_j)\} \).

Moreover, a direct consequence of minimizing Eq. (6) is that the optimal estimation of the alignment between the representation and attention context is proportional to the ratio of joint distribution and the product of marginals \( p_h(q) \cdot p_h(\text{att}_t(q)) \) which is the point-wise mutual information, and we can further have the following proposition with respect to the mutual information:

**Proposition 1.** The mutual information between the word representation \( q \) and its corresponding attention context \( \text{att}_t(q) \) is lower-bounded by the negative \( \text{Loss}_{s \rightarrow t} \) in Eq. (6) as:

\[
I(q, \text{att}_t(q)) \geq \log(k) - \text{Loss}_{s \rightarrow t},
\]

(7)

where \( k \) is the number of the negative samples.

The detailed proof can be found in [Oord et al., 2018]. Proposition 1 indicates that the lower bound of the mutual information \( I(q, \text{att}_t(q)) \) can be maximized by achieving the optimal NCE loss, which provides theoretical guarantee for our proposed method.

Our training schema over parallel sentences is mainly inspired by the bilingual skip-gram model [Luong et al., 2015] and invertibility modeling [Levinboim et al., 2015]. Therefore, the ultimate training objective should consider both forward \( (s \rightarrow t) \) and backward \( (t \rightarrow s) \) direction, combined with the mirror agreement loss. Technically, the final training objective is:

\[
\text{Loss} = \sum_{i} \text{Loss}_{s \rightarrow t}^{i} + \sum_{j} \text{Loss}_{t \rightarrow s}^{j} + \alpha \cdot \text{Loss}_{\text{disagree}},
\]

(8)

In the contrastive learning setting, \( q_i \) and \( \text{att}_t(q_i) \) can be sampled from different sentences. If \( q_i \) and \( \text{att}_t(q_i) \) are from the same sentence, \( i \neq j \); otherwise, \( j \) can be a random index within the sentence length. For simplicity, in this paper, we use \( q_i \) where \( i \neq j \) to denote the negative samples, although with a little bit ambiguity.

### Table 1:

| Method | EN-FR | FR-EN | sym | RO-EN | EN-RO | sym | DE-EN | EN-DE | sym |
|--------|-------|-------|-----|-------|-------|-----|-------|-------|-----|
| NNSA   | 22.2  | 24.2  | 15.7| 47.0  | 45.5  | 40.3| 36.9  | 36.3  | 29.5|

where \( \text{Loss}_{s \rightarrow t} \) and \( \text{Loss}_{t \rightarrow s} \) are symmetrical and \( \alpha \) is a loss weight to balance the likelihood and disagreement loss.

### 4 Experiments

#### 4.1 Datasets and Evaluation Metrics

We perform our method on three widely used datasets: English-French (EN-FR), Romanian-English (RO-EN) and German-English (DE-EN). Training and test data for EN-FR and RO-EN are from NAACL 2003 share tasks [Mihalcea and Pedersen, 2003]. For RO-EN, we merge Europarl v8 corpus, increasing the amount of training data from 49K to 0.4M. For DE-EN, we use the Europarl v7 corpus as training data and test on the gold alignments. All above data are lowercased and tokenized by Moses. The evaluation metrics are Precision, Recall, F-score (F1) and Alignment Error Rate (AER).

#### 4.2 Baseline Methods

Besides two strong statistical alignment models, i.e. FastAlign and GIZA++, we also compare our approach with neural alignment models where they induce alignments either from the attention weights or through feature importance measures.

**FastAlign** One of the most popular statistical method which log-linearly reparameterize the IBM model 2 proposed by [Dyer et al., 2013].

**GIZA++** A statistical generative model [Och and Ney, 2003], in which parameters are estimated using the Expectation-Maximization (EM) algorithm, allowing it to automatically extract bilingual lexicon from parallel corpus without any annotated data.

**NNSA** A unsupervised neural alignment model proposed by [Legrand et al., 2016], which applies an aggregation operation borrowed from the computer vision to design sentence-level matching loss. In addition to the raw word indices, fol-
lowing three extra features are introduced: distance to the diagonal, part-of-speech and unigram character position. To make a fair comparison, we report the result of raw feature in NNSA.

Naive Attention  Averaging all attention matrices in the Transformer architecture, and selecting the source unit with the maximal attention value for each target unit as alignments. We borrow the results reported in [Zenkel et al., 2019] to highlight the weakness of such naive version, where significant improvement are achieved after introducing an extra alignment layer.

Others  [Garg et al., 2019] and [Zenkel et al., 2020] represent the current developments in word alignment, which both outperform GIZA++. However, They both implement the alignment model based on a sophisticated translation model. Further more, the former uses the output of GIZA++ as supervision, and the latter introduces a pre-trained state-of-the-art neural translation model. It is unfair to compare our results directly with them. We report them in Table 2 as references.

4.3 Setup

For our method (SLUA), all the source and target embeddings are initialized by xavier method [Glorot and Bengio, 2010]. The embedding size $d$ and pooling window size are set to 256 and 3, respectively. The hyper-parameters $\alpha$ is tested by grid search from 0.0 to 1.0 at 0.1 intervals. For FastAlign, we train it from scratch by the open-source pipeline\(^3\). Also, we report the results of NNSA and machine translation based model(Sec.§4.2). All experiments of SLUA are run on 1 Nvidia K80 GPU. The CPU model is Intel(R) Xeon(R) CPU E5-2620 v3 @ 2.40GHz. Both FastAlign and SLUA take nearly half a hour to train one million samples.

4.4 Main Results

Table 2 summarizes the AER of our method over several language pairs. Our model outperforms all other baseline models. Comparing to FastAlign, we achieve 1.3, 0.5 and 2.2 AER improvements on EN-FR, RO-EN, DE-EN respectively.

Notably, our model exceeds the naive attention model in a big margin in terms of AER (ranging from 8.2 to 26.1) over all language pairs. We attribute the poor performance of the straightforward attention model (translation model) to its contextualized word representation. For instance, when translating a verb, contextual information will be paid attention to determine the form (e.g., tense) of the word, that may interfere the word alignment.

Experiment results in different alignment directions can be found in Table 1. The grow-diag symmetrization benifits all the models.

---

\(^3\)https://github.com/lilt/alignment-scripts
To better present the improvements brought by adding each component, we visualize the alignment case in Figure-3. As we can see, each component is complementary to others, that is, the attention map becomes more diagonally concentrated after adding the bidirectional symmetric attention and the agreement constraint.

| Table 3: Ablation results on EN-FR dataset. |
|-------------------------------------------|
| **Setup** | **P** | **R** | **F1** | **AER** |
| $\text{Loss}_{s\rightarrow t}$ | 74.9 | 86.0 | 80.4 | 20.9 |
| $\text{Loss}_{t\rightarrow s}$ | 71.9 | 85.3 | 77.3 | 23.3 |
| $\text{Loss}_{s\leftrightarrow t}$ | 81.5 | **90.1** | 86.1 | 14.1 |
| SLUA | **91.8** | 89.1 | **90.8** | **9.2** |

Table 4: Top 5 nearest English (EN) and German (DE) words for each of the following words: china, distinctive, easily, cat, love and January.

| EN | DE | EN | DE |
|---|---|---|---|
| china | chinas | distinctive | unverwechselbaren |
| chinese | chinese | peculiar | markante |
| china’ | chinesische | differences | charakteristische |
| republic | chinesischer | diverse | einzelnen |
|china’ | chinesischem | cat | love |
| cat | hundefelle | affection | liebt |
| dog | katzenfell | loved | liebe |
| toys | hundefellen | loves | lieben |
| cats | kuchen | passion | lieb |

5 Analysis

5.1 Alignment Case Study

We analyze an alignment example in Figure-4. Compared to FastAlign, our model correctly aligns “do not believe” in English to “glauben nicht” in German. Our model, based on word representation, makes better use of semantics to accomplish alignment such that inverted phrase like “glauben nicht” can be well handled. Instead, FastAlign, relied on the positional assumption, fails here.

Word Embedding Clustering

To further investigate the effectiveness of our model, we also analyze the word embeddings learned by our model. In particular, following [Collobert et al., 2011], we show some words together with its nearest neighbors using the Euclidean distance between their embeddings. Table-4 shows some examples to demonstrate that our learned representations possess a clearly clustering structure bilingually and monolingually.

We attribute the better alignment results to the ability of our model that could learn bilingual word representation.

6 Conclusion and Future Work

In this paper, we presented a super lightweight neural alignment model, named SLUA, that has achieved better alignment performance compared to FastAlign and other existing neural alignment models while preserving training efficiency. We empirically and theoretically show its effectiveness and reasonableness over several language pairs.

In future works, we would further explore the relationship between CLWEs and word alignments. A promising attempt is using our model as a bridge to unify cross-lingual embeddings and word alignment tasks. Also, it will be interesting to design alignment model in a non-autoregressive fashion [Gu et al., 2018; Wu et al., 2020] to achieve efficient inference.

---

\[ h(i, j, m, n) = - \left\{ \frac{1}{m} - \frac{1}{n} \right\} \]  # A feature \( h \) of position is introduced in FastAlign to encourage alignments to occur around the diagonal.
