ABSTRACT

Compare to the other metal ion, silver nanoparticles has wide application in the field of microbiology and pharmacology drug. The aim of present study was to synthesize cheap and eco-friendly silver nanoparticles on Commiphora gileadensis extract and evaluate its antimicrobial properties against selected bacterial strains. Aqueous extract of C. gileadensis was used for the synthesis of silver nanoparticles. These synthesized nanoparticles were characterized by using UV spectrophotometer, scanning electron microscope (SEM) and EDX. The characterization of AgNPs was carried out by UV-visible spectrum at λmax = 435 nm and the peak was correlated to the plasmonic nature of the particles as reported by number of earlier reports. In addition, EDX spectrum has been showed four peaks corresponding to the silver, zinc, carbon and oxygen. The results of present study indicated that the plant extract has very important role in the synthesis of AgNPs. Antibacterial activity of nanoparticles was evaluated using CFU method against E.coli O157:H7 and Methicillin-resistant Staphylococcus aureus (MRSA). Synthesized nanoparticles exhibit significant antibacterial activity against the infectious bacteria.

KEYWORDS

Commiphora gileadensis
Silver nanoparticles
E.coli
Multi-drug resistant Staphylococcus aureus (MRSA)

1 Introduction

Plant extracts are very important and many of them possess excellent biological properties (Abdul-Ghani & Amin, 1997; Adelawo et al., 2014; Shaheen et al., 2017). *Commiphora gileadensis* (syn. *C. opobalsamum*) is very common aromatic shrub and the Red sea area is known as its native land, which encompasses the territory of Saudi Arabia, Ethiopia, Oman, Yemen and some other countries of this region (Wineman et al., 2015). *C. gileadensis* was first discovered by Carl Linnaeus from Yemen and identified as “Balm of Gilead” (Amiel et al., 2012). It is also known as balsam and find very useful for perfume industry (Miller et al., 1988). All parts of the balsam such as bark, wood, seeds, extract (Al-siemi, 2013) and plant Sap (Iluz et al., 2010) are frequently used in pharmaceutical industries. Oil containing balsam sap was considered of prime an incentive in getting ready medicinal balsams (Iluz et al., 2010). According to Iluz et al. (2010), sap of balsam has capacity to cure cerebral pains. Crude methanol extract of *C. gileadensis* showed significant antibacterial activity against *E. coli*, and *Bacillus cereus*, with a minimum inhibitory concentration of 62.5 μg/ml (Al-siemi., 2013).

Medicinal properties of this plant are well known and because of this it became active ingredient of many therapeutic drugs. For instance, dried bark has been placed on wounds as a germicide, while a tincture of ground balsam bark is utilized to treat various skin sicknesses such as aggravations and dermatitis (Mittal et al., 2013). Researcher also reported hypotensive impact of *C. gileadensis*; oral administration of plant extract initiate muscarinic cholineric receptors of the mind, which initiate hypotensive impact which is at par the effect given by atropine sulfate (1-4 mg/kg). In addition, the leaves of balsam plant were utilized by Arab populaces as pain relieving, purgative and diuretic operators (Abdul-Ghani & Amin, 1997). Another investigation on rats revealed positive impact of plant extricate in the treatment of tentatively delivered stomach ulcers.

As stated earlier that extract of *C. gileadensis* has been used effectively against the bacterial growth but its high dosage was recommended. Therefore, it is utmost important to explore the alternate ways of using this plant extract for the bacterial growth inhibition. One of the effective way of using plant extracts is to utilize it for the synthesis of metal nanoparticles (Nps). In fact, metal Nps have been found highly significant in many studies related to various scientific fields (Ahmed et al., 2016a; Ali et al., 2017a; Ali et al., 2017b). Nowadays, plant extracts based Nps synthesis is one of the emerging field of nanotechnology. Various studies have reported the use of Silver nanoparticles (AgNps) in medicine, consumer products, food-technology and in other industrial products because of their exclusive chemical, catalytic, sensing, wound healing and physical properties (Ahmed et al., 2016a; Kamal et al., 2017; Haider et al., 2018; Ali et al., 2018a; Ali et al., 2018b). The AgNps have attained lots of attention because of their physical and chemical properties i.e., conductivity, catalytic activity, stability, being non-reactive & non-toxic and eco-friendly. Along with above mentioned properties, AgNps have extremely exalted antifungal, anti-inflammatory, antiviral and antibacterial activities and can be used in field of medicine for treating and diagnosis many chronic and acute diseases (Mittal et al., 2013; Bello et al., 2017b; Borros et al., 2018; Singh et al., 2018). The AgNps have great application in biomedical leading to the production of antiseptic sprays, dressing’s wound fabrics as well as antiseptic topical creams. Antibacterial and antifungal properties of the AgNps have also been reported, which demonstrated that AgNps disrupt cell membrane of the unicellular microbes leading to plasmolysis and hence kill the microbes (Khan et al., 2015; Wajid Ullah et al., 2016). In addition, disruption of the cell membrane results deterioration of membrane bound enzymes and cause deactivation of the enzymes, which cause death of microorganisms (Kamal et al., 2016; Bello et al., 2017b). The efficacy of the AgNps is greatly dependent of pH, size, ionic strength and capping agent of nanoparticles (Ahmed et al., 2016b). The synthesis of AgNps attained greater attention of the researchers because of their broader applications range and utilities in medicine and diagnosis against variety of cancers (Kuppusamy et al., 2016). Present study has been undertaken to assess the antimicrobial properties of AgNps synthesized on *C. gileadensis* extract. Moreover, these AgNps were synthesized against *E.coli* O157:H7 and a common antibacterial drug-resistant *Staphylococcus aureus* (MRSA).

2 Materials and Methods

2.1 Culturing of Pathogenic Bacteria

*E.coli* O157:H7 and multi drug-resistant *Staphylococcus aureus* MRSA which used as model bacteria were provided by King Fahad Center, King Abdulaziz University, Jeddah, Saudi Arabia. These microorganisms were used for the evaluation of bactericidal activity of synthesized nanoparticles. Nutrient agar (Sigma-Aldrich-70148) contains 5 g/L peptones, 2 g/L yeast extract, 1 g/L meat extract, 2 g/L sodium chloride and 15 g/L agar in deionized water was used for culturing these pathogenic bacteria. Media was prepared, autoclaved and pours into plates. Bacterial cells were transferred after solidification of media to culture plates.

2.2 Antibacterial Assessment

Colony forming unit (CFU) was used for the enumeration of bactericidal activity of silver nanoparticles synthesized using balsam plant extract. 100 μl of *E.coli* O157:H7 and multi-drug-resistant *S. aureus* (MRSA) were added to 10 ml of tube
containing nutrient broth medium along with silver nanoparticles. These tubes were incubated for 24 hours at 35°C. The samples were serially diluted and then spreaded onto nutrient agar containing plates. Nutrient Agar plates were incubated for 24 hours in order to check colony formation. Colony counter was used in order to count the bacterial colonies. Each treatment was repeated thrice.

### 2.3 Balsam extraction

A highly acclaimed method of obtaining the plant extract was used for this study. First, a whole plant of balsam was obtained from Baddar, Madinah region, Saudi Arabia. Plant material cut into small pieces and transfer to mortar containing liquid nitrogen. These pieces were crushed into fine pieces using mortar and then incubate on magnetic stirrer for 48 hours. Then filtered using filter paper concentrated and dried. This whole process was performed over a period of one week.

### 2.4 Biosynthesis of AgNPs

Aqueous extract of balsam was treated with a solution of AgNO₃. The treatment was performed in such a way that a solution of 1 Mm of AgNO₃ in final concentration was made. The mixture was stirred on a magnetic stirrer at 60 °C. Next, the synthesis AgNPs was indicated by color change (brown) of the solution. After two days, the solution was centrifuged and mixture was collected after discarding the supernatant. The collected AgNPs were washed with distilled water and air-dried for characterization and further studies.

### 2.5 Characterization of AgNPs

Generally, the characterization of NPs required determining the size, shape, surface area and dispersity because its properties are dependent on these features. Formation of AgNPs was confirmed by Ultraviolet-visible spectral analysis (UV-vis) spectroscopy. The absorbance spectra were recorded using a UV-Vis spectrophotometer at a wavelength range of 300–700 nm. Fourier Transform Infrared Spectroscopy (FTIR) was performed on FTIR Spectrometer to detect the possible functional groups in biomolecules present in the plant extract.

The surface morphology and size of the AgNPs were analyzed by employing a Scanning electron microscope (SEM) and energy dispersive X-ray spectroscopy (EDX). The particle size distribution and surface charge of AgNPs were determined using particle size analyzer (Zetasizernano ZS) at 25 °C with 90° detection angle.

### 3 Results and Discussion

#### 3.1 Antibacterial study

Various properties of the AgNps such as cryogenic super conducting materials, composite fibers, food industry, cosmetic products and in electronic gadgets have been well reported by various researcher's. In present study, the plant extract assisted AgNps have been used against the growth of two selected bacterial strains. Result of present study revealed that synthesized AgNPs have significant antibacterial activities and inhibiting the bacterial growth which is a major concern. Growth characteristics of *E. coli* O157:H7 and MRSA are shown in figure 1 & table 1.

| Treatments                | Incubation Periods | Reduction (%) |  |  |
|---------------------------|--------------------|---------------|---|---|
|                           | 12 Hrs (Cfu/ml)    | 24 Hrs (Cfu/ml) | 12 Hrs (Cfu/ml) | 24 Hrs (Cfu/ml) |
| Control (*E. coli* O157:H7) | 76×10⁶             | 102×10⁶       | 0                     | 0                     |
| *E. coli* O157:H7 + Ag Nps       | 0×10⁶              | 0×10⁶         | 100                   | 100                   |
| MRSA (Control)             | 86×10⁶             | 109×10⁶       | 0                     | 0                     |
| MRSA + Ag Nps              | 0×10⁶              | 0×10⁶         | 100                   | 100                   |

Figure 1 Growth of *E. coli* O157:H7 and Methicillin-resistant *Staphylococcus aureus* (MRSA) on Nutrient, plate agar showing inhibition in the presence of AgNPs
Efficacy of silver nanoparticles synthesized on *Commiphora gileadensis* extract against infectious bacteria

Results of study revealed that control (without AgNps nanoparticles) did not have any inhibition activity after 24 hours, while silver nanoparticles showed highest inhibition in *E.coli* O157:H7 and MRSA multiplication. This enhanced activity may be attributed to the silver nanoparticles. As *E.coli* is gram-negative bacteria that has a thin peptidoglycan layer and has complex cell wall containing two cell membrane (Kamal et al., 2016). The cell membrane of this bacteria is negatively charged, which may interact with the positively charged silver nanoparticle. This interaction alters cell membrane properties by forming pits and blocking the intake of nutrients to the cell subsequently AgNPs penetrating inside bacterial cell, thereby causes DNA damage (Khan et al., 2015). Other than this mechanism, these nanocomposite can also produce highly reactive species when heavy metals react with proteins which leads to the inactivation of proteins, i.e. hydrogen peroxide, superoxide’s or hydrogen radicals. In addition, toxicity studies of AgNPs was observed against Gram-positive *Staphylococcus aureus ATCC 35696* showed silver ions can interact with the thiol groups in proteins and inactivate them as well DNA molecules become condensed by losing its replication ability (Sondi & Salopek-Sondi, 2004).

3.2 UV-visible spectroscopy analysis

Figure 2 shows UV-vis spectrum of the synthesized silver nanoparticles. The spectrum was obtained after 48 h of mixing AgNO3 aqueous solution and balsam plant extract. The nearly colorless solution turned from faint light to yellowish and finally in brown color due to excitation of surface plasmonic nature in AgNps (Figure 3), which indicated the formation of the nanoparticles in the solution (Pourmortazavi et al., 2015).

In fact, strong absorbance occurred between the shapes of the surface plasmonic resonances (SPR) and wavelength, which related to the particle size and relative dimensions, consequently increasing in particle size makes the SPR peak move to longer wavelength. This observation was in line with other reports in the literature (Sondi & Salopek-Sondi, 2004). A single broad peak at $\lambda_{max} = 435$ nm was observed in a UV-vis spectrum. The peak was correlated to the plasmonic nature of the particles as reported by earlier researchers (Bello et al., 2017a). It has been reported by Bello et al. (2017a) that the peak positions in the UV-vis spectrum of smaller particles (20nm or below size) can be observed in the range of 400-420nm. The existence of peak at 435nm in this study reveals that the nanoparticles were larger than the 30nm size.

3.3 Scanning Electron Microscopy

Figure 4a represents a typical overview of the sample at very low magnification (X 7500). Analysis of figure reveals the presence of various size particles. Figure 4b is an enlarged view of synthesized AgNPs (X 15000 magnification). This image reveals that sample contained few nanometers sized particles. However, most of the particles were of smaller dimensions. Figure 4c also shows enlarge view of high magnification (X 15000 magnification), this revealed the presence of some viburnum leaf like structures in the sample at different locations. Final figure (Figure 4d) shows the FESEM image at highest magnification (X 60000), analysis of image (Figure 4d) showed the presence of ~70-115nm size AgNPs. These observations are in agreement with the UV-vis spectrum datum, which indicated that the particles were of larger dimensions than 35nm. These finding corroborate the results obtained by Chauhan et al. (2013) who reported the size of biologically synthesized Ag nanoparticles in the range of 20-70 nm.

3.4 Elemental Analysis

The elemental analysis data of the Ag nanoparticles have been represented in Figure 5. Further, EDX spectrum of these data have been shown in Figure 5a, there are four peaks corresponding to the
silver, zinc, carbon and oxygen. Obviously, the Ag signals were due to the Ag nanoparticles in the sample. The other elements in the sample might be due to the plant source. The total elemental composition of the other elements like carbon, oxygen and zinc in the form of element weight (%) was 5.17, 3.70 and 5.21 (total 14.07%) and atomic 27.99, 15.03 and 5.18 (total 48.2%), respectively as shown in Figure 5b. It was found that the most of the samples was composed of the Ag nanoparticles, as its weight percentage was highest (85.93%). Indeed, these results revealed strong signal in the silver region and confirmed the formation of AgNps.

3.5 Functional Groups analysis

The FTIR analysis of Ag Nps is shown in Figure 6. Since, the AgNPs were prepared using balsam plant aqueous extract; the organic compounds might be present because of the composition of balsam plant extract. This indicates that the plant extract has played dual role in synthesizing the AgNPs. First, it played a vital role in reducing Ag\(^{1+}\) ions and secondly it worked as capping agent for the synthesized AgNPs. A band of 3789 cm\(^{-1}\) is

| Element | Weight% | Atomic% |
|---------|---------|---------|
| C K     | 5.17    | 27.99   |
| O K     | 3.70    | 15.03   |
| Zn L    | 5.21    | 5.18    |
| Ag L    | 85.93   | 51.80   |

| Totals  | 100.00  |

Figure 5 EDX spectrum (a) and composition of the sample (b)
Efficacy of silver nanoparticles synthesized on Commiphora gileadensis extract against infectious bacteria

Conclusion

In this study, synthesis of AgNps using balsam extract was found efficient and eco-friendly. The characterization of the synthesized AgNps was assessed by several instrumental techniques and it reveals the successful formation of AgNps. Further, antibacterial ability of the synthesized AgNps was proven against E. coli O157:H7 and multi-drug-resistant Staphylococcus aureus (MRSA). Use of C. gileadensis medicinal plant extract for synthesis of AgNps, is a safer and economic. It can be used as potent broadb and antibacterial agents for biomedical applications.

Significance Statement

This study elaborated the antibacterial properties of silver nanoparticles against infectious bacteria. It may be beneficial for researcher in order to investigate the mechanism of silver nanoparticle bactericidal activity.
