ABSTRACT

Background: Intracranial migration of odontoid screws is a rare but serious complication of anterior odontoid screw fixation not often reported in literature by neurosurgeons. Here, we describe the second case in literature of intracranial migration of an odontoid screw.

Case Description: A 64-year-old neurologically intact patient with a type II odontoid fracture secondary to trauma underwent anterior odontoid screw fixation without any intraoperative complications. He tolerated the procedure well, and postoperative imaging demonstrated near anatomic correction of the fracture with satisfactory placement of the lag screw. Unfortunately, the patient was subsequently lost to follow up and he presented 7 months later for a routine outpatient computed tomography (CT) of the cervical spine, which demonstrated upward migration of the screw into the intracranial cavity abutting the medulla, with CT angiography of the neck also confirming the screw lying between the two vertebral arteries. Magnetic resonance imaging of the cervical spine also demonstrated the odontoid screw lying within close proximity to the ventral cervicomedullary junction, marginating the left vertebral artery. Subsequently, the patient was managed with removal of the odontoid screw and posterior cervical arthrodesis and instrumented fusion.

Conclusion: Our case demonstrates the rare but serious complication of intracranial odontoid screw migration, which we bring to the attention of the neurosurgical community. The recognition of risk factors for this complication and optimized management of this rare occurrence is important for surgeons to recognize.

Keywords: Anterior odontoid screw fixation, C2 odontoid screw, Postoperative intracranial migration

INTRODUCTION

Odontoid fractures are the most common cervical spine fractures with an occurrence of approximately 20% of all cervical fractures.¹,² Broadly speaking, odontoid fractures are divided into three categories, based on Anderson and d'Alonzo classification: (1) type I: oblique fracture through the tip of the dens; (2) type II: fracture at the base of the dens, in the junction with the axis body; and (3) type III: fracture extending into the body of the axis, with or without the involvement of atlantoaxial joint.¹,³ Of the three classes of odontoid fracture, type II is the most common, occurring approximately 65%–74% among elderly population.⁴,¹⁶
Treatment options for type II odontoid fractures can be conservative or surgical. Due to the patient discomfort and high risk of nonunion and mortality with conservative approaches in a subpopulation of patients, surgical stabilization is typically favored and is becoming the norm for this subpopulation.\textsuperscript{8,19} Among surgical techniques, the two widely practiced procedures are anterior odontoid screw fixation (AOSF) and posterior cervical instrumented fusion (PCIF). While each of these procedures has unique indications and contraindications, AOSF is preferred by some spine surgeons due to its minimally invasive nature, minimal blood loss, high fusion rate from 89% to 100%, quicker postoperative recovery with preservation of normal atlantoaxial rotation, and maximum postoperative cervical spine motion.\textsuperscript{10,19} However, this procedure is technically quite challenging with screw breakage, malposition, and loss of fixation as some of the many possible complications – hardware failure occurs generally in a delayed fashion and is often associated with pseudoarthrosis.

We present a rare case of a 64-year-old male who presented with a posttraumatic type II odontoid fracture which was managed through AOSF. A routine computed tomography (CT) scan of the cervical spine 7 months later demonstrated intracranial migration of the screw, with the patient undergoing subsequent removal of the screw and PCIF. To the best of our knowledge, intracranial migration of odontoid screws has only been described in literature once, making our case, the second reported case of upward migration of an odontoid screw. We provide a comprehensive review of literature demonstrating postoperative migration of anterior odontoid screws and discuss the current management that spine surgeons must face when dealing with this rare, yet critical, complication.

**CASE DESCRIPTION**

A 64-year-old male presented as an intoxicated pedestrian who was involved in a hit-and-run incident. Initial trauma workup demonstrated that the patient had sustained a type II odontoid fracture [Figure 1]. He subsequently underwent AOSF for this fracture, without any intraoperative complications. He tolerated the procedure well and postoperative imaging demonstrated near anatomic correction of the fracture with satisfactory placement of the lag screw [Figures 2 and 3]. Postoperatively, the patient was to attend physical therapy. Unfortunately, the patient was subsequently lost to follow up and he presented 7 months later for a routine outpatient CT of the cervical spine, which demonstrated upward migration of the screw into the intracranial cavity abutting the medulla [Figure 4], with CT angiography of the neck also demonstrating the screw lying between the two vertebral arteries [Figure 5]. The patient had also obtained a magnetic resonance imaging of the cervical spine which demonstrated the odontoid screw lying within close proximity to the ventral cervicomedullary junction, marginating the left vertebral artery [Figures 6 and 7]. Although he did not exhibit any neurological symptoms at this
time, given the migration of the screw, there was nonunion of the patient’s fracture with increased risk of poor recovery and neurological deterioration. He was subsequently taken for an anterior removal of the odontoid screw with posterior open treatment and reduction, C1-4 posterolateral arthrodesis and instrumented fusion, and Brooks sublaminar wire placement of C1-2 posterior instrumentation [Figure 8]. He tolerated the procedure well and remained intact neurologically postoperatively.

DISCUSSION

Fractures of the C2 odontoid process are the most common cervical injury.[1,4] These fractures lead to instability of the atlantoaxial joint which may result in cervical myelopathy and cervical spine compression. Management of these fractures can be done either conservatively by immobilizing the joint using a rigid or halo brace or surgically by AOSF or PCIF.[2,12] However, nonsurgical management of these fractures is generally associated with poor outcomes and morbidity.[2] While there is no current consensus on the best surgical treatment of type II odontoid fractures, AOSF has become popular among spine surgeons due to its minimal

Figure 6: Sagittal magnetic resonance imaging sequences of the cervical spine demonstrating the odontoid screw lying within the ventral cervicomedullary junction.

Figure 7: Axial magnetic resonance imaging sequences of the cervical spine demonstrating the odontoid screw lying within the ventral cervicomedullary junction.

Figure 8: Sagittal computed tomography images of the cervical spine demonstrating subsequent removal of the odontoid screw with C1–4 posterior cervical instrumented fusion.
In an interesting case reported by Simonin et al., an odontoid screw migrated upward over a decade after AOSF and caused progressive dysphagia and for immediate and robust stability of the fracture without compromising the normal atlantoaxial rotation. There has been some consideration in literature evaluating two-screw fixation versus single screw fixation. Jenkins et al. demonstrated that in a series of 42 consecutive patients with odontoid screw placement, there was no significant difference in the successful union rates between one and two-screw fixation techniques (fusion was found to be 81% and 85%, respectively). Moreover, Sasso et al. showed that the two-screw fixation technique did provide an increased stiffness in extension loading, with no significant difference in the biomechanical fixation rate between one- and two-screw fixation methods. Thus, we did not find it necessary to perform a two-screw fixation in our patient.

Postoperative anterior or posterior migration of odontoid screws is rarely reported in literature, being reported in literature only three times [Table 1]. Our patient sustained a posttraumatic type II odontoid fracture which was initially managed with AOSF and caused progressive dysphagia which we bring to the attention of the neurosurgical community.

To rectify the fixation and nonfusion of the fracture, we performed a PCIF and C1-C4 posterolateral arthrodesis and instrumented fusion following anterior screw removal. While PCIF is typically done to fuse C1-C2, we extended the fusion from C1-C4 to provide additional robustness to the fusion given that our patient was elderly and that his fracture still showed significant nonfusion in spite of 7-month post-AOSF.

**CONCLUSION**

Intracranial migration of odontoid screws is a rare but serious complication of AOSF. Here, we report the second case in literature of intracranial migration of an odontoid screw in a neurologically intact patient, managed with subsequent removal and PCIF. Our case demonstrates the rare but serious complication of intracranial odontoid screw migration, which we bring to the attention of the neurosurgical community.

### Table 1: Cases of odontoid screw migration in type II odontoid fractures.

| Authors and year | Age* (years) | Cause of migration | Time to screw migration** | Presenting symptoms | Site of migration | Complications | Outcome |
|------------------|--------------|--------------------|--------------------------|---------------------|------------------|---------------|---------|
| Lee et al., 2012 | 27, F        | Malposition of screw and local infection | 3 years | Dysphagia | Pharyngeal soft tissue | None | Surgical screw removal without complications |
| Simonin et al., 2016 | 70, M | Pseudoarthrosis of fracture and erosion of C1-C2 facet joints | 10 years | Neck pain and quadriaparesis | Medulla oblongata | None | Surgical screw removal and posterior C1-C2 fusion without complications |
| Leitner et al., 2017 | 78, M | Suboptimal fixation of screw | 8 years | Neck tension and dysphagia | Gastrointestinal tract | Esophageal perforation | Excreted through gastrointestinal tract |

*Age: Male = M, Female = F  **Time to screw migration: 3 years, 10 years, 8 years **Site of migration: Pharyngeal soft tissue, Medulla oblongata, Gastrointestinal tract **Complications: Surgical screw removal without complications, Surgical screw removal and posterior C1-C2 fusion without complications, Excreted through gastrointestinal tract **Outcome: Surgical screw removal without complications, Surgical screw removal and posterior C1-C2 fusion without complications, Excreted through gastrointestinal tract
