781. Non-Tuberculous Mycobacterium: Often a Missed Entity
Saaraa B, MBBS; Aval, MD1; MRCPC(UK); Atul Kalaker, DNB and S. P. Byotra, MBBS, MD2; Sri Ganga Ram Hospital, New Delhi, India
Session: 70. Tuberculosis and Other Mycobacterial Infections
Thursday, October 4, 2018: 12:30 PM

Background. Initially referred to as Lady Windermere syndrome, the prevalence of Non-Tuberculous Mycobacterium (NTM) is on the rise globally. In India, the TB capital of the world, these infections still go unrecognized, as the clinical presentation of all mycobacterial diseases are similar. This is of clinical relevance as misdiagnosis may lead to unnecessary or inappropriate antimicrobial treatment.

Methods. We conducted a retrospective study of adults suspected of having mycobacterial infection. Records of patients admitted with suspected TB from January 2015 to December 2017 were reviewed; clinicoradiological features were correlated with the organisms isolated; treatment given and outcomes were recorded.

Results. Out of 877 suspected patients, 245 patients had microbiologically proven Mycobacterium tuberculosis and 34 had NTM (3.8%). Pulmonary infection was seen in 19 cases (56%), rest were extra pulmonary (34%).

Fever was the commonest symptom (62%) others being cough (50%), breathlessness (41%), hemoptysis (15%), weight loss (5%), chest pain (3%) and back ache (12%). Symptoms were prolonged (31 month) in 65% of cases. Radiologically, cavitations were seen in 42%, lung nodules (32%), and infiltrates (32%) were commonly seen. Upper zone predilection was noted in 68% of cases. Past tuberculosis was the major risk factor seen in 42% of cases while 26% were immunocompromised. Macrolide resistance was noted in none of our patients. Twenty-four out of 34 cases were AFB smear positive (71%), but M Tuberculosis growth was negative. Our series includes four patients who did not respond to first-line anti-tubercular therapy (ATT) and were suspected to have multi-drug-resistant (MDR) tuberculosis. Cultures later grew NTM and the patients improved with macrolide regime.

Conclusion. NTM is an underreported infection in a developing country like India with a high TB prevalence. Similar clinical features and morphology create a greater diagnostic dilemma. Usage of molecular techniques and AFB culture should be considered in ATT nonresponders before starting them on MDR regime.

782. Risk Factors, Clinical Characteristic, and Treatment Outcomes for Nontuberculous Mycobacterial Disease in Mexico
Bruno Rodriguez, MD; Roberta de Leon, MD; Nestor Rodriguez, MD; Miriam Bobadilla-Del Valle, PhD; Alfredo Ponce-De-Leon, MD and José Sifuentes-Osornio, MD, FIDSA1; Infectious Diseases, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; Department of Medicine, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico
Session: 70. Tuberculosis and Other Mycobacterial Infections
Thursday, October 4, 2018: 12:30 PM

Background. Nontuberculous mycobacteria (NTM) cause diverse clinical manifestations in multiples clinical setting, and in the past years, there has been an increasing prevalence and variability among geographic regions, this associated with a diversity of hosts and clinical manifestations. We objective was evaluated the clinical and microbiologic characteristic, and the treatment outcomes related to slowly growing mycobacteria (SGM) and rapidly growing mycobacteria (RGM).

Methods. When conducting a retrospective study between January 2001 and December 2017, retrospectively their medical records were reviewed for obtainments of site of isolation or infection, comorbidities or predisponent condition, clinical and radiographic presentation, and treatment outcomes.

Results. A total of 90 patients with isolated of RGM and 87 within SGM were evaluated among these M. avium and M. fortuium were the most predominant species. HIV infection was the predominant risk factor for SGM infections (P < 0.001); the conditions associated to RGM infections were cancer (P = 0.0287); diabetes mellitus (DM) (P = 0.01418), chronic kidney disease (CKD) (P = 0.04662), use of immunosuppressive medication (P < 0.001), and use of invasive device only were present in the RGM group. In the RGM group, lung infection was the most common site of infection (43%); in the SGM group, the disseminated disease was the most common (54%). The time of treatment was more prolonged in the SGM group (196 vs. 229 days, P = 0.0309). In the RGM group, the rate of cure in the subgroup of Mycobacterial stream infections and disseminated infection was 15 vs. 5, P = 0.0146. In the analysis of lung infection who meet the IDSA/ATS criteria were divided into the group with treatment and the group without treatment, the outcomes were not significant in both groups.

Conclusion. The NTM infection is an important cause of disease in patients with chronic conditions such as cancer, immunosuppressive medication, CKD, use of invasive device, and DM. HIV infection persist as the first risk factor for M. avium disseminated disease, the treatment for this latter condition in spite of more prolonged, it had a lower rate of cure. The treatment of lung infections for NTM must be individualized although the IDSA/ATS criteria are met.

783. Characterization of Non-tuberculous Mycobacteria Isolates in a National Mycobacterial Laboratory in Panama: 2012–2015
Sofia Zavala, MD1; Samantha Rosas, MD2; Arlene Galo, MD3; Nestor Sosa, MD4; German Henostroza, MD5 and Ana Belen Arazu Rodriguez, MD6-7; University of Alabama at Birmingham, Birmingham, Alabama, “Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama City, Panama, University of South Florida, Tampa, Florida, “Hospital Santu Tomas, Panama City, Panama
Session: 70. Tuberculosis and Other Mycobacterial Infections
Thursday, October 4, 2018: 12:30 PM

Background. Nontuberculous mycobacteria (NTM) are becoming more frequent isolated in microbiology laboratories. There is no standardized diagnostic treatment, and/or monitoring of patients with NTM disease. We described the experience of the Panama National Mycobacteriological Laboratory in isolating NTM in patients suspected to have active tuberculosis in Panama.

Methods. Data registries of the National TB Program Laboratory of Panama between 2012 and 2015 were reviewed. Demographic information, relevant history, sample source, and isolate identified for each specimen obtained at the time of specimen submission was extracted. Identification of mycobacterial species were made using culture and PCR. Data were exported to an Excel workbook and a descriptive analysis was performed using STATA.

Results. A total of 4,545 samples were received during this period. Of these, 288 (6.3%) were not processed. From the remaining 4,257 samples, 705 (16.5%) were negative, 2,783 (65.6%) were positive for M. tuberculosis, and 769 (18%) were confirmed NTM. NTM species identification was achieved in 715 (93%) using PCR. Median age was 55 years (0 – 92); 49.4% were male. The most frequent NTM isolate was M. avium complex in 172 (22.3%) samples, followed by M. fortuium in 131 (17%). M. chelonae was isolated in 98 (12.7%) samples, M. gordone in 50 (6.5%), M. scrofulaceum in 20 (2.6%), and M. triviale in 16 (2.0%). NTM isolation steadily rose over the study period with 490 (63.7%) of the samples being from 2015 and 465 (94.5%) of these typed by PCR. Specimens mainly originated from the Panamanian metropolitan area (88.2%) and were mostly sputum samples (70.8%).

Conclusion. Nontuberculous mycobacteria represented an important proportion of isolates among TB suspect in Panama. The implementation of more sensitive diagnostic techniques is increasing the recovery of NTM. Further evaluation of the clinical significance of these findings is required for appropriate guideline implementation.

Disclosures. G. Henostroza, Aeras: Investigator, Grant recipient.

784. The Changing Epidemiology of Disseminated Mycobacterium avium complex in the United States
Khalid M. Douss, MD, FACP, CABIM1; Rafael Ponce-Terashima, MD2; Daniel Van Aartzen, MD3; Alejandro De La Hor, MD Student3 and John L. Johnson, MD1, Infectious Disease, University Hospitals, Case Western Reserve University, Cleveland, Ohio, 3Case Western Reserve University, Cleveland, Ohio, 3University Hospitals, Case Western Reserve, Cleveland, Ohio, 3Grupo de Investigación en Enfermedades Infecciosas, Hospital Universitario San Ignacio, Pontificia Universidad Javeriana, Bogotá, Colombia, 2Tuberculosis Research Unit, Department of Medicine, Case Western Reserve University and University Hospitals Cleveland Medical Center, Cleveland, Ohio
Session: 70. Tuberculosis and Other Mycobacterial Infections
Thursday, October 4, 2018: 12:30 PM

Background. The epidemiology of disseminated Mycobacterium avium complex (DMAC) infection in the United States is changing. Previously most DMAC occurred in adults with advanced AIDS. Since the development of effective antiretroviral therapy, the incidence of DMAC in AIDS has fallen more than 10-fold. Malignancy, immunosuppression, and tumor necrosis factor inhibitors are known risk factors for DMAC. We sought to describe the epidemiology of DMAC disease in HIV seronegative patients in the United States.

Methods. We performed a Retrospective analysis of a commercial database (Exployre Inc., Cleveland, OH). This database contains an aggregate of Electronic Health Record data from 26 major integrated healthcare systems in the United States from 1999 to present. Exployre contains de-identified information from over 50 million patients, 360 hospitals, and over 317,000 providers. We identified a total of 571 persons diagnosed with DMAC, based on Systemized Nomenclature of Medicine-Clinical
