ABSTRACT

Background
Urinary schistosomiasis is caused by an intravascular infection with parasitic *Schistosoma haematobium* worms. The adult worms typically migrate to the venous plexus of the human bladder and excrete eggs which the infected person passes in their urine. Chronic infection can cause substantial morbidity and long-term complications as the eggs become trapped in human tissues causing inflammation and fibrosis. We summarised evidence of drugs active against the infection. This is a new edition of a review first published in 1997.

Objectives
To evaluate the efficacy and safety of drugs for treating urinary schistosomiasis.

Search methods
We searched the Cochrane Infectious Diseases Group Specialized Register, MEDLINE, CENTRAL, EMBASE and LILACS and reference lists of articles up to 23 May 2014.

Selection criteria
Randomized controlled trials (RCTs) of antischistosomal drugs and drug combinations compared to placebo, no intervention, or each other.

Data collection and analysis
Two researchers independently screened the records, extracted the data and assessed risk of bias. The primary efficacy outcomes were parasitological failure (defined as the continued presence of *S. haematobium* eggs in the urine at time points greater than one month after treatment), and percent reduction of egg counts from baseline. We presented dichotomous data as risk ratios (RR), and continuous data as mean difference (MD), alongside their 95% confidence intervals (CIs). Where appropriate we combined trials in meta analyses or tables. We assessed the quality of evidence using the GRADE approach.

Main results
We included 30 RCTs enrolling 8165 participants in this review. Twenty-four trials were conducted in children in sub-Saharan Africa, and 21 trials were over 20 years old. Many studies were assessed as being at unclear risk of bias due to inadequate descriptions of study methods.
Praziquantel

On average, a single 40 mg/kg dose of praziquantel reduced the proportion of people still excreting eggs in their urine by around 60% compared to placebo at one to two months after treatment (treatment failure: RR 0.42, 95% CI 0.29 to 0.59, 864 participants, seven trials, high quality evidence). The proportion of people cured with praziquantel varied substantially between trials, from 22.5% to 83.3%, but was higher than 60% in five of the seven trials. At one to two months following praziquantel treatment at 40 mg/kg, the mean number of schistosome eggs in the urine was reduced by over 95% in five out of six trials (678 participants, six trials, high quality evidence).

Splitting praziquantel 40 mg/kg into two doses over 12 hours probably has no benefits over a single dose, and in a single trial of 220 participants the split dose caused more vomiting (RR 0.5, 95% CI 0.29 to 0.86) and dizziness (RR 0.39, 95% CI 0.16 to 0.94).

Metrifonate

A single dose of metrifonate 10 mg/kg reduced egg excretion (210 participants, one trial, at eight months), but was only marginally better than placebo at achieving cure at one month (RR 0.83, 95% CI 0.74 to 0.94, 142 participants, one trial). In a single trial comparing one, two and three doses, the absolute number of participants cured improved from 47% after one dose to 81% after three doses (93 participants, one trial, low quality evidence).

Two small trials compared 40 mg/kg single dose praziquantel with two or three doses of 10 mg/kg metrifonate and found no clear evidence of differences in cure (metrifonate 2 x 10 mg/kg at one month: RR 1.03, 95% CI 0.8 to 1.34, 72 participants, one trial; metrifonate 3 x 10 mg/kg at three months: RR 0.33, 95% CI 0.07 to 1.57, 100 participants, one trial. In one trial both drugs performed badly and in one trial both performed well.

Other drugs

Three trials have evaluated the antimalarial artesunate; with inconsistent results. Substantial antischistosomal effects were only seen in one of the three trials, which was at unclear risk of bias due to poor reporting of the trial methods. Similarly, another anti-malarial mefloquine has been evaluated in two small trials with inconsistent effects.

Adverse events were described as mild for all evaluated drugs, but adverse event monitoring and reporting was generally of low quality.

Authors' conclusions

Praziquantel 40 mg/kg is the most studied drug for treating urinary schistosomiasis, and has the strongest evidence base.

Potential strategies to improve future treatments for schistosomiasis include the combination of praziquantel with metrifonate, or with antimalarial drugs with antischistosomal properties such as artesunate and mefloquine. Evaluation of these combinations requires rigorous, adequately powered trials using standardized outcome measures.

Update pending

Studies awaiting assessment

The CIDG is currently examining a new search conducted in April 2019 for potentially relevant studies. These studies have not yet been incorporated into this Cochrane Review.

PLAIN LANGUAGE SUMMARY

Drugs for treating urinary schistosomiasis

What is urinary schistosomiasis and how is it treated?

Urinary schistosomiasis is a disease caused by infection of people with the parasitic worm Schistosoma haematobium. These worms live in blood vessels around the infected person’s bladder and the worm releases eggs which are released in the person’s urine. If the urine is passed into ponds or lakes, the eggs can hatch and infect people that are washing or swimming there. Infection can cause blood in the urine and if left untreated can eventually lead to anaemia, malnutrition, kidney failure, or bladder cancer. Urinary schistosomiasis is diagnosed by looking for worm eggs in the urine.

The disease occurs mainly in school-aged children and young adults in sub-Saharan Africa. The drug currently recommended for treatment is praziquantel, which can be given as a single dose, but other drugs such as metrifonate, artesunate, and mefloquine have also been evaluated.

After examining the research published up to 23th May 2014, we included 30 randomized controlled trials, enrolling 8165 children and adults.
What does the research say?

On average, the standard dose of praziquantel cures around 60% of people at one to two months after treatment (high quality evidence), and reduces the number of schistosome eggs in the urine by over 95% (high quality evidence).

Metrifonate, an older drug no longer in use, had little effect when given as a single dose but an improved effect when given as multiple doses two weeks apart. Two trials compared three doses of metrifonate with the single dose of praziquantel and found similar effects.

Two more recent trials evaluated a combination of artesunate and praziquantel compared to praziquantel alone. In one trial artesunate improved cure and in one it made no difference.

Authors conclusions

Future treatments for schistosomiasis could include combining praziquantel with metrifonate, or with artesunate, but these need to be evaluated in high quality trials.
## SUMMARY OF FINDINGS

### Summary of findings for the main comparison. Praziquantel 40 mg/kg versus placebo for treating urinary schistosomiasis

| Outcomes                      | Illustrative comparative risks* (95% CI) | Relative effect (95% CI) | No of participants (trials) | Quality of the evidence (GRADE) |
|-------------------------------|-----------------------------------------|--------------------------|-----------------------------|---------------------------------|
|                               | Assumed risk                            | Corresponding risk       |                             |                                 |

| Adverse events                | —                                        | —                        |                             |                                 |

The basis for the assumed risk is the mean risk in the control groups across trials. The corresponding risk (and its 95% CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI). CI: Confidence interval; RR: Risk ratio.

GRADE Working Group grades of evidence

- **High quality**: Further research is very unlikely to change our confidence in the estimate of effect.
- **Moderate quality**: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
- **Low quality**: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

1. No serious risk of bias: Several trials were at unclear or low risk of selection bias. However, a sensitivity analysis excluding these trials still found a strong effect.
2. No serious inconsistency: Six of the seven trials found large consistent effects. The seventh trial found no difference, this may be explained by the different diagnostic criteria used in this trial.
3. No serious indirectness: These seven trials are all conducted in children in endemic areas of sub-Saharan Africa.
4. No serious imprecision: The result is statistically significant and the 95% CI is narrow around a clinically important effect.
5. No serious imprecision: The trials are small and most did not report tests of statistical significance, however the differences are large.
6. No serious risk of bias: This trial was well conducted.
7. Downgraded by 1 for serious indirectness: Only a single trial reports this outcome. Further trials from different settings would be needed to be confident in this effect.
8. Downgraded by 1 for serious imprecision: This trial is underpowered.
9. Downgraded by 1 for serious risk of bias: both trials had inadequate sequence generation and allocation concealment.
10. No serious inconsistency: Low statistical heterogeneity.
11. No serious imprecision: only two trials reported this outcome. CIs are narrow. The effect is not statistically significant and does not appear to be clinically important, when compared to the baseline data.
12. Downgraded by 2 for serious risk of bias: Three trials do not comment on adverse events. Six trials made comments that praziquantel was generally well tolerated and no statistically significant differences were noted. However, adverse events were poorly reported in all six trials such that meta-analysis, and assessment of other quality criteria was not possible.

Summary of findings 2. Praziquantel 40 mg/kg single dose versus 30 mg/kg single dose

Praziquantel 40 mg/kg compared to praziquantel 30 mg/kg for treating urinary schistosomiasis

| Outcomes                      | Illustrative comparative risks* (95% CI)                      | Relative effect (95% CI) | No of participants (trials) | Quality of the evidence (GRADE) |

| At 6 months          | The mean reduction in control groups ranged from an 97% reduction to a 99% reduction. | The mean reduction in the intervention groups ranged from a 46% reduction to a 99% reduction | 0.89   | 117           | low    |
|                      | (0.47 to 1.67) |                    | (1 trial) | 11,12,13 | very low |

#### Haematuria

| Failure Type | Control Group | Intervention Group | RR     | No. of Studies | GRADE |
|--------------|---------------|--------------------|--------|---------------|--------|
| At 6 months  | 26 per 100    | 23 per 1000        | 0.85   | 117           | low    |
|              | (12 to 44)    |                    | (1 trial) | 11,12,13 | very low |

#### Proteinuria

| Failure Type | Control Group | Intervention Group | RR     | No. of Studies | GRADE |
|--------------|---------------|--------------------|--------|---------------|--------|
| At 6 months  | 15 per 100    | 13 per 100         | 0.85   | 117           | low    |
|              | (5 to 31)     |                    | (1 trial) | 11,12,13 | very low |

### Adverse events

| Type       | RR     | No. of Studies | GRADE |
|------------|--------|---------------|--------|
|            |        |               |        |

*The basis for the assumed risk (for example, the median control group risk across studies) is provided in footnotes. The corresponding risk (and its 95% CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

**Cf:** Confidence interval; **RR:** Risk ratio.

**GRADE Working Group grades of evidence**

- **High quality:** Further research is very unlikely to change our confidence in the estimate of effect.
- **Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
- **Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
- **Very low quality:** We are very uncertain about the estimate.

---

1. Downgraded by 1 for serious risk of bias: None of the trials described a method of allocations concealment or blinding outcome assessors.
2. No serious inconsistency: No statistical heterogeneity in the relative effect of the two praziquantel doses. However, treatment failure with praziquantel 40 mg/kg ranged from 0% to than more than 50%.
3. No serious indirectness: All trials were conducted in sub-Saharan Africa, in patients aged from seven to 20 years.
4. Downgraded by 1 for serious imprecision: None of the individual studies found statistical significant differences, and overall, the meta-analysis remains underpowered to confidently detect an effect.
5. No serious inconsistency: Three of the four trials report the difference was not statistically significant. The fourth trial did not report significance but effects were similar.
6. Downgraded by 1 for serious imprecision: We were unable to pool the data, and as such cannot exclude a small difference in effect between the two doses in a pooled analysis.
7. No serious inconsistency. Low statistical heterogeneity.
8. No serious imprecision. The effect is of no clinically important difference between the two doses, and the 95% CIs are narrow.
9. Downgraded by 1 for serious inconsistency: In one trial praziquantel 40 mg/kg had a very low percent egg reduction of 46%. The reasons for this are unclear.
10. Unable to assess precision as the data were not pooled.
11. Downgraded by 1 for serious risk of bias: This trial did not adequately describe allocation concealment. Participants and clinicians were not blinded.
12. Downgraded by 1 for serious indirectness: Only one trial from one setting.
Summary of findings 3. Praziquantel 40 mg/kg multiple doses versus single dose

GRADE Working Group grades of evidence

**High quality:** Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** We are very uncertain about the estimate.

1. Downgraded by 1 for serious risk of bias; the single trial reporting this outcome did not adequately describe sequence generation, allocation concealment and blinding of participants, clinicians or outcome assessors.
2. No serious inconsistency. Only one trial.
3. No serious indirectness. This single trial was conducted in children in rural sub-Saharan Africa.
4. Downgraded by 1 for serious imprecision. The trial was underpowered.
5. Downgraded by 1 for serious risk of bias. The trial did not report on sequence generation and allocation concealment. The study described blinding of participants, clinicians and outcome assessors.
6. No serious imprecision. CIs are narrow and both CI limits have clinically important effects. The trial is adequately powered for this outcome.
7. No serious imprecision. The difference in effect between metrifonate and placebo group is large.
8. None of the trials reported on adverse events.

**Summary of findings 5. Artesunate versus placebo**

Artesunate compared to placebo for treating urinary schistosomiasis

**Patient or population:** patients with treating urinary schistosomiasis

**Settings:** endemic settings

**Intervention:** artesunate 4 mg/kg for three days

**Comparison:** placebo

| Outcomes | Illustrative comparative risks* (95% CI) | Relative effect (95% CI) | No of participants (studies) | Quality of the evidence (GRADE) |

*The basis for the assumed risk (for example, the median control group risk across studies) is provided in footnotes. The corresponding risk (and its 95% CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio.

**GRADE Working Group grades of evidence**

**High quality:** Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** We are very uncertain about the estimate.

1 Downgraded by 1 for serious risk of bias. One trial described sequence generation, allocation concealment and blinding adequately, whereas the second study did not.
2 Downgraded by 1 for serious inconsistency. One of the trials (at high risk of bias) reported a large effect, while the other trial (at low risk of bias) detected no effect.
3 No serious indirectness. The trials were conducted in Gabon and Nigeria in patients of a similar age range.
4 Downgraded by 1 for serious imprecision. The CI is very wide and reaches from no benefit to a significant benefit after treatment.
5 No for serious inconsistency. Percent egg reductions the studies reported were similar.
6 Downgraded by 1 for serious imprecision. The meta analysis is underpowered.
7 No serious risk of bias. The one trial reporting the outcome reported adequately on sequence generation, allocation concealment and blinding.
8 No serious inconsistency: only one trial.
9 No serious indirectness: This trial was conducted in school children in Gabon.
10 Downgraded by 2 for very serious imprecision: only one trial reporting 74 events in 119 participants evaluated this outcome.
11 Downgraded by 1 for serious risk of bias: only one trial was blinded. Both trials reported on adverse events, but the methods are unclear.
12 Downgraded by 1 for imprecision. One study reported on clinically diagnosed outcomes per treatment group, but was underpowered to confidently detect a difference.
### Summary of findings 6. Praziquantel and artesunate versus praziquantel

**Praziquantel plus artesunate compared to praziquantel alone for treating urinary schistosomiasis**

**Patient or population:** patients with urinary schistosomiasis  
**Settings:** Countries endemic for urinary schistosomiasis  
**Intervention:** Praziquantel plus artesunate  
**Comparison:** Praziquantel alone

| Outcomes                    | Illustrative comparative risks* (95% CI) | Relative effect (95% CI) | No of participants (trials) | Quality of the evidence (GRADE) |

*The basis for the assumed risk (for example, the median control group risk across studies) is provided in footnotes. The corresponding risk (and its 95% CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio.

**GRADE Working Group grades of evidence**

- **High quality:** Further research is very unlikely to change our confidence in the estimate of effect.
- **Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
- **Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
- **Very low quality:** We are very uncertain about the estimate.

1 Downgraded by 1 for serious risk of bias: only one out of two studies did report adequate random sequence generation, allocation concealment and blinding or participants and clinicians, while the other study did not provide enough information to allow a judgement.
2 No serious inconsistency. Both studies favour the combination of Praziquantel and ARS over Praziquantel alone.
No serious indirectness. The trials were conducted in rural communities in Gabon and Nigeria, in children (6 to 15 years) and young adults (4 to 20 years).

- Downgraded by 1 for serious imprecision: Only two studies were included in this comparison. The effect size, described by the 95% CI, ranged from a very small, clinically non-important effect to a clinically important effect.
- Downgraded by 1 for serious inconsistency: Egg reduction varied widely between the two trials.
- Downgraded by 1 for serious imprecision: Only two studies reported this outcome. The one study that reporting this outcome described adequate random sequence generation, allocation concealment, and blinding.
- Downgraded by 2 for serious imprecision: Only one small study reported this outcome. The outcome is not statistically significant with wide 95% CI. This study did not provide enough information to allow a judgment regarding sequence generation, allocation concealment, and blinding.
- Downgraded by 1 for serious imprecision: Only one study reported on adverse events. The study was underpowered, and no difference in adverse events was detected between treatment groups.
**BACKGROUND**

Urinary schistosomiasis, also called bilharzia or snail fever, is an intravascular infection caused by parasitic *Schistosoma haematobium* worms. It is endemic in sub-Saharan Africa, the Arabian peninsula and the Middle East. According to the World Health Organization (WHO), at least 243 million people required treatment for schistosomiasis in 2011 (WHO 2013), and more than 700 million people live in endemic areas (WHO 2014).

The WHO currently recommends regular chemoprophylaxis with praziquantel for populations at risk to prevent the long term consequences of infection. These programmes usually target school children (Table 1), but may be extended to the whole community in high risk settings (King 2011).

**Description of the condition**

Human infection with *S. haematobium* is acquired through contact with water bodies containing cercariae, the larval form of the parasite. The cercariae are able to penetrate human skin and migrate via blood vessels to the liver, where they mature into male and female forms for reproduction. Typically, they then migrate further to the venous plexus of the urinary bladder, and begin to produce eggs which the infected person excretes in their urine (Gryseels 2006). If these eggs reach water, they hatch into miracidia, infect specific freshwater snails which act as intermediate hosts, before emerging as cercariae that can infect humans (Gray 2011; Ross 2002).

Any illness associated with acute infection is typically mild, but chronic schistosomiasis can cause considerable morbidity with chronic pain, anaemia, fatigue, under nutrition and reduced exercise tolerance (King 2005). A review of 124 observational studies and 11 randomized controlled trials (RCTs) in 2005 estimated that up to 15% of people infected with any form of schistosomiasis suffer disabling long-term complications (King 2005). The main pathological process occurs when schistosome eggs become trapped in the tissue around the bladder and ureters causing chronic inflammation, which may obstruct the ureters, damage the kidneys, and lead to bladder cancer. Occasionally, eggs can become trapped in other tissues such as the brain and spinal cord (WHO 1985).

Two-thirds of all infected persons are schoolchildren (aged five to 14 years), and the intensity of infection with *S. haematobium* is highest in children aged ten to 14 years (WHO 1985).

The standard test for urinary schistosomiasis is urine filtration and microscopic examination of the urine sample (WHO 1991). The urine sample is passed through a filter paper and the eggs retained on the filter are counted either with or without staining. Sedimentation and centrifugation is less commonly used for urine concentration (Cook 2003). High urine egg counts are related to high infection intensity.

Parasitologists define cure when eggs can no longer be detected in one or more urine samples using standard methods. Besides parasitological cure, researchers also record the relative reduction in egg output after treatment compared to pre-treatment levels. This outcome, expressed as % egg reduction, is an indirect estimate of a reduction of the worm burden (Cook 2003).

Blood and protein excretion in the urine is usually elevated in urinary schistosomiasis and decreases when the infection resolves. The most commonly used test is a dipstick test. Ultrasound can demonstrate organ involvement of the urinary tract as well as its resolution.

**Description of the intervention**

Praziquantel is the current treatment for urinary schistosomiasis recommended by the WHO (WHO 2006). Historically, metrifonate was also used but this fell out of favour due to the need for multiple doses (Feldmeier 1999; WHO 1998). More recently, there has been interest in the antischistosomal properties of artemisinin derivates and mefloquine, more commonly used for treating malaria (Utzinger 2004).

Praziquantel is an pyrazinoisoquinoline derivative with activity against adult worms of all schistosome species (*S. mansoni*, *S. intercalatum* and *S. japonicum*), but not against maturing worms. Praziquantel has a rapid onset of action. It is well-tolerated, can be given as a single dose (Utzinger 2004) and paediatric formulations are available (Stothard 2013).

Metrifonate, an organophosphorous cholinesterase inhibitor, is active against *S. haematobium* but not against other schistosome species (Utzinger 2004).

Artemisinin, extensively used as potent antimalarial, has highest activity against immature schistosomes. Artemisinins are safe and well-tolerated (Utzinger 2004).

**How the intervention might work**

After treatment with praziquantel, the worms appear to die quickly but egg excretion continues for several weeks. There are several possible reasons for this:

- **Firstly**, some worms might not have been mature at the time of praziquantel treatment and therefore not killed by praziquantel (Cioli 2003). Maturation of the worms after infection takes four to six weeks, and after two months eggs can be detected in the urine.
- **Secondly**, the patient might have been re-infected (Cioli 2003).
- **Thirdly**, dead eggs still wander out of the tissue into the urine several weeks after clearing adult worms (Taylor 1988 ZWE). Therefore, a follow-up four to six weeks after treatment is useful (Renganathan 1998). There is also considerable variation in daily urinary egg output (Cook 2003).

Although there is concern that *S. haematobium* might develop resistance against praziquantel (Fenwick 2006), there is no clinically relevant evidence for resistance up to now (Doenhoff 2008).

In endemic settings, reinfection with *S. haematobium* is likely, and cure (often defined as complete cessation of egg excretion) is not a sustainable long term goal. However, reduction of infection intensity results in clinical improvement, low morbidity and prevention of long term complications. Therefore, WHO promotes morbidity control rather than cure as an objective for schistosomiasis control programmes (WHO 2002).
Why it is important to do this review

At present, praziquantel as the only drug in use that is exposed to resistance development. It is therefore important to monitor its performance and to assess the effects of other drugs against urinary schistosomiasis.

Dosing regimens for subgroups such as highly infected patient groups, incremental benefits of drug combinations, double dosing and optimal interval between doses have to be determined to inform control programmes for urinary schistosomiasis.

Paediatric schistosomiasis has gained attention as a public health problem, and evaluation of existing treatment studies is indicated.

OBJECTIVES

To evaluate the efficacy and safety of drugs for treating urinary schistosomiasis.

METHODS

Criteria for considering studies for this review

Types of studies

Randomized controlled trials.

Types of participants

Patients diagnosed with urinary schistosomiasis by:

- detection of macro or microhaematuria;
- identification of schistosome eggs by urine microscopy;
- detection of parasite antigens in blood or urine.

Types of interventions

Intervention

Drugs used to treat urinary schistosomiasis. Drugs considered as obsolete (such as ambilhar, oltipraz and niridazole) were not included. Metrifonate was included.

Control

Placebo, no intervention, an alternative regimen of the same drug, or an alternative drug used to treat urinary schistosomiasis.

Types of outcome measures

Primary outcomes

- Parasitological failure at one month post-treatment (as defined by the trial authors);
- Percent egg reduction at one month.

Secondary outcomes

- Parasitological failure at time-points > one month;
- Percent egg reduction from baseline at > one month;
- Clinical outcomes: resolutions of signs and symptoms (for example, haematuria and proteinuria);
- Anaemia (decrease of the number of red blood cells or the quantity of haemoglobin in the blood);
- Growth outcomes (gain in body weight, body length).

Adverse events

- Serious adverse events;
- Other adverse events

Search methods for identification of studies

We attempted to identify all relevant trials regardless of language and publication status (published, unpublished, in press, under review and in progress).

Electronic searches

We searched the following databases using the search terms outlined in Appendix I: The Cochrane Infectious Diseases Group Specialized Register (23 May 2014); Cochrane Central Register of Controlled Trials (CENTRAL), published in The Cochrane Library (2014, Issue 4); MEDLINE (1966 to 23 May 2014); EMBASE (1974 to 23 May 2014); and LILACS (1982 to 23 May 2014). We also searched the metaRegister of Controlled Trials (mRCT) using 'Schistosoma haematobium' as the search term (23 May 2014).

Searching other resources

We checked the reference lists of all studies identified by the above methods for additional studies relevant to this review.

Data collection and analysis

Selection of studies

Vittoria Lutje, the Cochrane Infectious Diseases Group (CIDG) Information Retrieval Specialist, searched the literature and retrieved trial titles and abstracts.

VK and FZ independently screened the results of the search and retrieved full trial reports of all potentially relevant trials. Then, VK and FZ independently assessed each trial for inclusion using an eligibility form based on the inclusion criteria. We resolved any discrepancies by discussion with PG.

Data extraction and management

VK and FZ independently extracted data using pre-tested standardized forms. We resolved any differences through discussion with PG. For each trial we extracted details of the trial methods, participants, interventions and outcomes.

VK and FZ extracted the number of participants randomized and number of participants followed up in each treatment arm. For dichotomous outcomes, we extracted the number of participants experiencing the event in each group. For continuous outcomes summarized as geometric means, we extracted means and their standard error, if reported. If the data were presented as arithmetic means, we extracted arithmetic means and their standard deviations (SD), if reported, for each treatment group. Where continuous data were summarized as medians and ranges, these were extracted and entered into tables.

VK and FZ double-entered the data and cross-checked to minimise errors. VK tried to contact trial authors for clarification or insufficient of missing data when necessary and summarised data reported in multiple publications as one single data set.
Assessment of risk of bias in included studies

VK and FZ independently assessed the risk of bias of each trial using an assessment form based on the Cochrane Collaboration’s ‘Risk of bias’ tool (Higgins 2008). DS verified the assessment results.

We assessed the risk of bias for six domains: sequence generation; allocation concealment; blinding (of participants, personnel, and outcome assessors); incomplete outcome data; selective outcome reporting; and other sources of bias. We categorized these judgments as low, high or unclear risk of bias.

For sequence generation, allocation concealment and blinding, we quoted the method as described in the trial in the Characteristics of included studies tables. For blinding, we stated the blinding method and who was blinded separately for different outcomes. For incomplete outcome data, we assigned a judgement for different outcomes (for example, loss to follow-up at different time points).

We resolved disagreements by discussion or consultation. Where risk of bias was unclear, we attempted to contact the trial authors for clarification.

Measures of treatment effect

We presented dichotomous outcomes as risk ratios (RR), and continuous outcomes as mean differences or geometric mean ratios. All results are shown with a 95% confidence interval (CI).

Unit of analysis issues

For trials including more than two comparison groups, we split and analysed as individual pair-wise comparisons. When conducting meta-analysis we ensured that participants and cases in the placebo group were not counted more than once, by dividing the placebo cases and participants evenly between the intervention groups.

Dealing with missing data

The primary analysis is a complete case analysis where the number of evaluable participants at each time point is used as the denominator.

Assessment of heterogeneity

We assessed heterogeneity by inspecting forest plots for overlapping CIs and outlying data. We applied the Chi² test with a P value < 0.10 to indicate statistically significant heterogeneity, and the I² statistic with a value of greater than 50% to indicate moderate heterogeneity.

Assessment of reporting biases

We planned to evaluate the possibility of publication bias by constructing funnel plots, but there were too few trials within each comparison to make this meaningful.

Data synthesis

We analysed the data in pair-wise comparisons using Review Manager (RevMan). We stratified the primary analysis by drug dose and the time point after treatment. Data were combined in meta-analyses using a fixed-effect model. If we detected moderate heterogeneity but still considered combination of the trials to be appropriate we used a random-effects model. We presented data which could not be presented in forest plots in tables (medians, means without measure of variance, ranges).

We assessed quality of evidence using the GRADE approach, and displayed the results in ‘Summary of Findings’ tables. The GRADE approach defines quality as a measure of ‘our confidence in the effect estimates’ and defines four levels of quality: high, moderate, low and very low. The evidence from RCTs is rated as ‘high quality’ but can be downgraded where there are major concerns about: 1) the risk of bias of the trials; 2) inconsistency between the trial results; 3) a mismatch between the question being asked and the trial setting, population, intervention or control; 4) the trial being underpowered; or 5) evidence of publication bias.

Subgroup analysis and investigation of heterogeneity

We planned to conduct the following subgroup analyses to explore the potential causes of heterogeneity. However, there were too few trials within each comparison to make this meaningful: patient age (children versus adults), intensity of infection, endemicity.

Sensitivity analysis

Data were insufficient to assess the robustness of results by sensitivity analyses to evaluate risk of bias components and the effects of missing data.

RESULTS

Description of studies

Results of the search

Following database searches, we identified 116 individual citations, and a further 40 potential studies after we checked trial abstracts. Following abstract screening, we assessed 71 full text articles for inclusion. Figure 1 shows the flow diagram of these trials.
Figure 1. Study flow diagram

104 records identified through database searching (1st search, 06 August 2012)
12 records identified through database search update (09 May 2013)

156 records after duplicates removed

156 records screened (title or abstract)

85 records excluded based on title or abstract

71 full-text articles assessed for eligibility

31 full-text articles excluded, of these, 10 studies excluded after a change in protocol
40 full-text articles reported on 30 trials

30 trials included in qualitative synthesis

30 trials included in quantitative synthesis (meta-analysis)
One trial contributed data to summary tables only
Included studies
We included 30 RCTs, enrolling 8965 participants, and reported in 39 publications. Twenty trials were over 20 years old, and only eight were published since the year 2000.

Settings
All but one trial were conducted in sub-Saharan Africa; 13 trials from East Africa: Somalia (one), Sudan (three), Tanzania (two), Kenya (six), Malawi (one); 13 trials from West Africa: Cameroon (two), Gabon (three), Niger (two), Mali (one), Nigeria (two), Cote d’Ivoire (one), Ghana (one), Gambia (one); and three trials from southern Africa: Zimbabwe (two), and Zambia (one). Most trials were based in rural settings, but two were conducted in peri-urban or semi-rural settings, three were from urban settings, and in one trial the setting was not described. The remaining trial was conducted in an urban setting in Saudi Arabia.

Twenty trials were based in schools and one in a college, seven in villages, farms or settlements, one in antenatal clinics and two in referral hospitals.

Participants
Twenty-four trials enrolled school-age children and young adults, although the exact age-range varied; age six to 20 years (16 trials), age five to 18 years (three trials), age two to 23 years (five trials). Two trials enrolled adults only, and four trials didn’t clearly state the age range.

Interventions
Eight trials compared praziquantel with placebo, and 14 trials published between 1981 and 2009 compared different doses or regimens of praziquantel.

Five trials compared metrifonate with placebo, and seven trials published between 1983 and 1990 directly compared the efficacy of praziquantel and metrifonate.

More recently, three trials published between 2001 and 2009 evaluated artesunate as single agent or in combination with praziquantel, and two trials published in 2009 and 2011 evaluated mefloquine.

Excluded studies
We excluded 65 studies for the reasons given in the ‘Characteristics of excluded studies’ table.

Risk of bias in included studies
Many trials lacked adequate descriptions of methods to allow judgements on risk of bias, and so have been classified as unclear (see Figure 2).
Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included trial.
Figure 2. (Continued)

| Study                        | Allocation | Blinding | Incomplete outcome data | Selective reporting | Other potential sources of bias |

### Allocation

Fourteen trials adequately described a random method of sequence generation, but only six described a method of allocation concealment and could be considered at low risk of selection bias (Abden Abdi 1989 SOM; Basra 2012 GAB; Borrmann 2001 GAB; Olds 1999 KEN; Pugh 1983 MWI; Sacko 2009 MLI).

### Blinding

Ten trials reported adequate attempts to blind participants and trial staff to treatment allocation, six trials were unblinded and blinding was unclear in the remaining trials. Seven trials reported adequate blinding of outcome assessors.

### Incomplete outcome data

Many trials had high levels of attrition, particularly at later time points. When trials presented cure or failure rates as percentages, we were unable to assess attrition. We considered the risk of attrition bias to be unclear in 13 trials and high in nine trials.

### Selective reporting

We found evidence of reporting bias in one trial, as trial authors did not present pre-specified outcomes. In three trials, selective reporting was at unclear risk of bias.

### Other potential sources of bias

Trial authors reported baseline imbalances in two trials, which we identified as sources of other bias.

The trials were mostly funded by funds, trusts or international agencies (see Characteristics of included studies tables). Eight trials did not declare funding, four received drug donations and only two trials declared funding by pharmaceutical companies (both Dafra Pharma).

### Effects of interventions

See: **Summary of findings for the main comparison**  Praziquantel 40 mg/kg versus placebo for treating urinary schistosomiasis;  **Summary of findings 2**  Praziquantel 40 mg/kg single dose versus 30 mg/kg single dose;  **Summary of findings 3**  Praziquantel 40 mg/kg multiple doses versus single dose;  **Summary of findings 4**  Metrifonate 3 x 7.5 mg/kg given two weeks apart versus placebo;  **Summary of findings 5**  Artesunate versus placebo;  **Summary of findings 6**  Praziquantel and artesunate versus praziquantel

#### Section A: Praziquantel

**Praziquantel 40 mg/kg single dose versus placebo (comparison 1)**

On average, a single 40 mg/kg dose of praziquantel reduces the proportion of people still excreting eggs at one to two months after treatment by around 60% compared to placebo, and reduces the mean number of eggs excreted by over 95%.

Eight trials compared a single 40 mg/kg dose of praziquantel with placebo or no treatment in schoolchildren in sub-Saharan Africa. We have listed the definitions of parasitological failure in Table 2.

#### Parasitological failure

Praziquantel 40 mg/kg as a single dose reduced parasitological treatment failure by around 60% at one to two months compared to placebo (RR 0.42, 95% CI 0.29 to 0.59; 864 participants, seven trials, Analysis 1.1). The absolute level of treatment failure with praziquantel ranged from 16.6% (McMahon 1979 TZA) to 77.5% (de Jonge 1990 SDN). Treatment failure with placebo was greater than 80% in all seven trials and over 90% in four trials.

Four trials reported follow-up beyond two months (Analysis 1.1). Failure rate increased over time in two trials, as might be expected in areas of schistosomiasis transmission as people become re-infected (McMahon 1979 TZA; Pugh 1983 MWI). However, treatment outcomes improved in Taylor 1988 ZWE over time, with moderate
reductions in treatment failure at one month and three months and a 70% reduction at six months. The trial authors stated that this improvement might have been due to excretion of remaining eggs from the urinary tract over time.

The fourth trial, de Jonge 1990 SDN, found no difference in treatment failure between praziquantel and placebo at any time point. The trial authors used a more sensitive diagnostic method (three urine samples, filtration of the whole volume up to 350 mL when the 10 mL urine sample contained fewer than 10 eggs) and a strict definition of cure (no excretion of eggs, no viability testing of eggs). This may explain the high failure rates observed despite high percent egg reductions comparable to other trials.

Stephenson 1989 KEN reported treatment failure at eight months, its only time point. A single dose of praziquantel reduced treatment failure by 86% compared to placebo (RR 0.14, 95% CI 0.08 to 0.22; 209 participants, one trial, Analysis 1.1).

Six trials reported parasitological failure stratified by intensity of infection; the categorisation of strata varied between trials (642 participants, see Appendix 2). At the first follow-up at four to six weeks, three out of four trials had a tendency to higher failure in participants with higher infection intensity. The pattern attenuated at later time points.

**Percent egg reduction**

Seven trials reported mean urine egg counts per 10 mL urine at baseline, and at one to two months after a single dose of praziquantel 40 mg/kg or placebo (867 participants, seven trials, see Table 3), although we were only able to reliably interpret this data for six trials (678 participants).

The mean egg count was reduced by more than 95% at one to two months following praziquantel in five trials, and by 75% in one trial. In the placebo group the change in mean egg count ranged from a 53% decrease to a 115% increase.

Percent egg reduction in the praziquantel group remained high (> 95%) in all three trials reporting at three months, and in all four trials at six months. Percent egg reduction was variable in the placebo group, ranging from 26% increase to 54% reduction at three months and from 5% to 64% reduction at six months (see Table 4). One additional trial, Stephenson 1989 KEN, reported percent egg reduction at eight months as its only time point (209 participants, see Table 4). Percent egg reduction after praziquantel was 99% compared to 5% with placebo.

Five trials reported percent egg reduction stratified by intensity of infection (764 participants, Appendix 2). At four to six weeks, all trials reported percent egg reductions over 90% across the strata. Percent egg reduction as a relative measure was at least as high in heavy infections as in mild infections, but post-treatment egg counts as an absolute measure tended to be higher in people with high intensity infections. This pattern persisted at later time points.

**Clinical resolution**

At eight weeks the proportion of patients with persistent haematuria (defined as > 5 erythrocytes/mL) was lower in those given praziquantel than placebo in one small trial which reported this (RR 0.53, 95% CI 0.33 to 0.84; 119 participants, one trial, Analysis 1.2). There were substantial reductions in the mean number of erythrocytes in the urine in three trials at one to two months, but we could not combine these data in a meta-analysis (357 participants, three trials, see Appendix 3).

Proteinuria was reduced by 65% to 84% at one to two months after praziquantel compared to increases in the placebo groups (238 participants, two trials, see Appendix 3).

Two trials reported mean haemoglobin at baseline and at six to eight months after treatment with no difference between groups (mean difference -0.08, 95% CI -0.24 to 0.09; 727 participants, two trials, Analysis 1.3).

Three trials measured a variety of growth parameters (Befidi Mengue 1992 CMR; Olds 1999 KEN; Stephenson 1989 KEN). Two trials reported little or no effect on the outcomes measured (Befidi Mengue 1992 CMR; Olds 1999 KEN). The third trial (Stephenson 1989 KEN) reports 14 measures, some of which are reported as statistically significant, but all appear to be of no or only borderline clinical importance (see Appendix 4). Most notably, there is a reported increase in children's physical fitness as measured by the Harvard Step test. The difference in mean improvement between groups was 6.8% at five weeks (mean end scores 81.2% praziquantel versus 75.5% placebo). Scores between 68% and 82% are considered average. Children that took praziquantel also gained 1.2 kg more weight than those in the control group, however baseline differences between groups were of a similar magnitude to this effect.

**Adverse events**

Of nine trials, six (with 1286 participants) commented on adverse events. Only four described the methods used for data collection, but rarely reported them in detail (see Appendix 5). Adverse events were usually monitored in the first days after medication. Only two trials actually reported numbers of adverse events, and only abdominal pain was reported by both trials. The absolute number of adverse events was low and none were more common with praziquantel than placebo (see Analysis 1.4). The other trials summarized narratively with comments such as “both treatments were well tolerated” (see Appendix 5).

**Praziquantel 40 mg/kg versus lower doses (comparison 2)**

Praziquantel doses of 20 to 40 mg/kg result in similar reductions in mean egg excretion, but 40 mg/kg is marginally superior at achieving cure.

Ten trials compared praziquantel 40 mg/kg with lower doses: 30 mg/kg (seven trials), 20 mg/kg (three trials), and 10 mg/kg (three trials). All trials were conducted in sub-Saharan Africa in schoolchildren, apart from one trial, which recruited college students and army recruits.

Treatment with praziquantel 40 mg/kg had fewer treatment failures than lower doses when measured at four to six weeks after treatment (versus 30 mg/kg; RR 0.76, 95% CI 0.59 to 0.99; 401 participants, four trials, Analysis 2.1, versus 20 mg/kg; RR 0.74, 95% CI 0.59 to 0.93; 338 participants, two trials, Analysis 2.1). However, there was no difference between 40 mg/kg and 30 mg/kg at two to three months (517 participants, five trials, Analysis 2.2), or six months after treatment (699 participants, six trials, Analysis 2.3).

In the five trials comparing praziquantel 40 mg/kg and 30 mg/kg, the mean number of eggs excreted was reduced by greater than
90% with both doses and without significant differences between groups (495 participants, five trials, see Table 5).

In trials comparing 40 mg/kg and 20 mg/kg, again the mean number of eggs excreted was reduced by more than 95% for both doses and differences in percent egg reduction appeared small (636 participants, four trials, see Appendix 2). Treatment with praziquantel 40 mg/kg appeared to result in greater percent egg reductions than 10 mg/kg (357 participants, three trials, see Appendix 2).

One small trial from Kenya (King 1989 KEN) reported similar numbers of participants with persistent haematuria or proteinuria at three months with praziquantel 40 mg/kg, 30 mg/kg and 20 mg/kg, but 40 mg/kg was superior to 10 mg/kg (haematuria at three months: RR 0.35, 95% CI 0.21 to 0.58, 119 participants, one trial, Analysis 2.4; proteinuria at three months: RR 0.25, 95% CI 0.12 to 0.51; 119 participants, one trial, Analysis 2.5). A larger trial by the same authors comparing 40 mg/kg and 20 mg/kg (King 2002 KEN) detected fewer participants with haematuria at six weeks following praziquantel 40 mg/kg (RR 0.63, 95% CI 0.47 to 0.86; 245 participants, one trial, Analysis 2.6), and fewer participants with proteinuria (RR 0.66, 95% CI 0.46 to 0.96; 245 participants, one trial, Analysis 2.7). These differences were still observed at nine months (haematuria: RR 0.59, 95% CI 0.44 to 0.78; 215 participants, one trial, Analysis 2.8; proteinuria RR 0.67, 95% CI 0.5 to 0.9; 214 participants, one trial, Analysis 2.9). King 2002 KEN also reported ultrasound findings (bladder thickening, bladder irregularity and hydronephrosis) before and after treatment with praziquantel 40 mg/kg and 20 mg/kg respectively, but the results were inconclusive (264 participants, see Appendix 6).

Six of these trials did not comment on adverse events. Four trials described the methods of data collection, but often in insufficient detail; two out of four trials used active, prospective surveillance for adverse events (Appendix 5). Two trials stated for all treatment arms collectively that adverse events after praziquantel treatment were mild and transient. Two trials reported numbers of adverse events with no differences between groups (183 participants, Analysis 3.2).

**Praziquantel 40 mg/kg single dose versus split dose (comparison 3)**

Splitting the dose of praziquantel 40 mg/kg into two 20 mg/kg doses over 24 hours has not been shown to improve tolerability and may actually cause more vomiting and dizziness.

Three trials compared the single 40 mg/kg dose with a split dose regimen giving two doses of 20 mg/kg over 24 hours. There was no statistically significant difference in treatment failure at one month (RR 0.75, 95% CI 0.51 to 1.11; 374 participants, three trials), three months (RR 0.74, 95% CI 0.45 to 1.2; 361 participants, three trials), or six months (RR 0.83, 95% CI 0.51 to 1.35; 234 participants, three trials, Analysis 3.1). Similarly percent egg reduction was over 90% for both groups (332 participants, three trials, see Appendix 2).

These trials enrolled 191 participants for a single dose of praziquantel 40 mg/kg and 195 participants for a split dose of 2 x 20 mg/kg. All trials used active surveillance for adverse events (see Appendix 5). Adverse events were generally reported to be mild and transient. However one trial reports significantly more vomiting and dizziness with the split dose compared to the single dose (vomiting: RR 0.5, 95% CI 0.29 to 0.86; dizziness: RR 0.39, 95% CI 0.16 to 0.94; 373 participants, three trials, Analysis 3.2).

**Praziquantel 40 mg/kg single dose versus multiple doses (comparison 4 and 5)**

There are too few trials to determine the optimal frequency and timing of repeated praziquantel dosing.

Two trials compared the standard single dose of praziquantel (40 mg/kg) with two or three doses given at two or three week intervals, and found no statistically significant differences in parasitological failure (Analysis 4.1, Analysis 4.2), percentage egg reduction (Appendix 2), or clinical resolution (Appendix 3; Analysis 4.3).

One additional very small trial from a high transmission setting in Gabon (van den Biggelaar 02 GAB), compared praziquantel 40 mg/kg every three months for two years to a single dose of praziquantel 40 mg/kg given at the beginning of the trial. At two years, patients who received only one dose of praziquantel had almost three times the risk of treatment failure compared to multiple doses (RR 2.71, 95% CI 1.47 to 5.00; 62 participants, one trial, Analysis 5.1). Percent egg reduction was 96% after multiple doses and 80% after a single dose of praziquantel at two years (90 participants, see Table 6). These effects were no longer apparent one year after the last praziquantel dose.

These trials did not report on adverse events.

**Section B: Metrifonate**

**Metrifonate single dose versus placebo (comparison 6)**

A single dose of metrifonate 10 mg/kg probably reduces egg excretion but is only marginally better than placebo at achieving cure.

Two trials compared a single dose of metrifonate to placebo, although one trial only reported outcomes at a single time point eight months after treatment (Stephenson 1989 KEN).

In the first trial (Pugh 1983 MWI), 80% of those treated with metrifonate continued to excrete eggs one month after treatment which was only marginally better than placebo (RR 0.83, 95% CI 0.74 to 0.94; 142 participants, one trial, Analysis 6.1), and no difference was seen at six months (RR 0.94, 95% CI 0.87 to 1.02; 102 participants, one trial, Analysis 6.1).

In the second trial (Stephenson 1989 KEN), 61% of those treated with metrifonate continued to excrete eggs eight months after treatment compared with almost 100% who received placebo (RR 0.63, 95% CI 0.54 to 0.73, 210 participants, one trial, Analysis 6.1). Egg excretion was also reduced by more than 90% eight months after treatment compared to just 5% with placebo (210 participants, see Appendix 2).

The second trial also reported mean haemoglobin at baseline and eight months (with no difference between groups, Analysis 6.2), and various measures of nutrition and growth (see Appendix 4). However, this trial had three arms and the nutritional measures are reported for the metrifonate and praziquantel groups combined. Consequently, we were unable to evaluate the effect of metrifonate. Trial authors did not report adverse events.
Section C: Praziquantel versus metrifonate

Praziquantel 40 mg/kg single dose versus metrifonate 10 mg/kg single dose (comparison 10)

Single dose praziquantel 40 mg/kg was more effective than single dose metrifonate 10 mg/kg in curing patients and reducing egg excretion.

Three trials compared the standard dose of praziquantel 40 mg/kg with a single dose of metrifonate 10 mg/kg, although one trial only reported outcomes at eight months after treatment (Stephenson 1989 KEN).

In the first trial (Pugh 1983 MWI), parasitological failure at one month was halved with praziquantel 40 mg/kg compared to metrifonate 10 mg/kg (RR 0.46, 95% CI 0.34 to 0.61; 183 participants, one trial, Analysis 10.1). Treatment failure increased in both groups over the following five months which the authors suspect was due to egg excretion by maturing worms, as transmission and re-infection were low in the trial setting (Analysis 10.1). The second trial (Wilkins 1987 GMB), also found praziquantel to be superior to metrifonate at two to three months as its only time point (RR 0.45, 95% CI 0.27 to 0.75; 72 participants, one trial, Analysis 10.1).

The third trial (Stephenson 1989 KEN), found substantial reductions in both treatment failure (RR 0.21, 95% CI 0.13 to 0.36; 208 participants, one trial, Analysis 10.1) and egg excretion (see Appendix 2), with praziquantel compared to metrifonate. Haemoglobin levels measured in this trial were higher in the praziquantel treatment arm both at baseline and at follow-up (208 participants, one trial, Analysis 10.2). The trial did not detect a difference in growth parameters between groups but does not report them separately (see Appendix 4).

None of the trials reported on adverse events.

Praziquantel 40 mg/kg single dose versus multiple doses of metrifonate 10 mg/kg

Two small trials found no difference in parasitological treatment failure or egg excretion between single dose praziquantel 40 mg/kg and two or three doses of metrifonate 10 mg/kg.

Two small trials compared praziquantel 40 mg/kg single dose to two and three doses of metrifonate 10 mg/kg given two weeks apart. The trials detected no difference in parasitological treatment failure at different time points and with different metrifonate regimens. However, in one trial both drugs performed poorly (de Jonge 1990 SDN), and in one trial both performed well (Al Aska 1990 SAU) (see Analysis 10.3). The trial where both drugs performed poorly for parasitological failure has been discussed above and this is likely to be due to the very sensitive method for detecting eggs. In this trial, both drugs reduced mean egg excretion by over 98% at one month and five months (see Appendix 2), and a decrease in haematuria by over 90% at one month. Reduction in proteinuria was almost 80% in both groups (see Appendix 3).

Only Al Aska 1990 SAU reported adverse events; dizziness was more common after praziquantel (RR 2.9, 95% CI 1.59 to 5.3; 100 participants, one trial, Analysis 10.4). Dizziness (20% in the praziquantel group and 10% in the metrifonate group) and adverse events were mild and transient. Headache and abdominal pain were most common.
abdominal pain (12% both in the praziquantel and metrifonate group) were the most common side effects (Appendix 5).

Additional comparisons of praziquantel and metrifonate

One small trial compared a single dose of praziquantel 30 mg/kg to three doses of metrifonate 10 mg/kg given two weeks apart and found no difference in parasitological failure at two months, but a statistically significant difference in favour of praziquantel at four months (RR 0.24, 95% CI 0.07 to 0.8; 52 participants, one trial, Analysis 10.5). Egg reduction at four months was above 98% in both treatment groups (Appendix 2). In this trial, abdominal pain was more common in the metrifonate group (RR 0.33, 95% CI 0.12 to 0.92; 60 participants, one trial, Analysis 10.6), while no difference was detected for the eight other clinically diagnosed symptoms reported.

One large population-based trial from Kenya compared praziquantel 40 mg/kg given once a year to metrifonate 10 mg/kg given three times a year. After one year, this trial detected no difference in treatment failure, haematuria or proteinuria (1400 participants, one trial, Analysis 10.7), but mean egg excretion was reduced by over 80% in both groups at one year (Appendix 2). There continued to be no difference in parasitological failure at two years, but praziquantel was superior in the third year (RR 0.62, 95% CI 0.42 to 0.93; 827 participants one trial, Analysis 10.8). Ultrasound findings, recorded in a sub-sample of children, were inconclusive (373 participants, Appendix 6).

One further small trial compared a single dose of praziquantel 40 mg/kg with a combination of praziquantel 10 mg/kg and metrifonate 10 mg/kg. At two to three months there was no difference in treatment failure (72 participants, one trial, Analysis 10.9). Percent egg reduction was 99.4% after praziquantel alone and 92.9% after the combination treatment (see Appendix 2).

Section D: Artesunate

Artesunate versus placebo (comparison 11)

The two placebo controlled trials of artesunate had inconsistent results, and the single trial at low risk of bias found only a modest effect on egg excretion compared to placebo.

Two trials compared artesunate 4 mg/kg once daily for three days with placebo. The two trials had inconsistent results on parasitological failure, with one trial finding no difference between artesunate and placebo, and one finding lower treatment failures with artesunate at eight weeks (251 participants, two trials, Analysis 11.1). The trial finding an effect was at unclear risk of both selection and detection bias due to an inadequate description of trial methods (Inyang Etoh 2009 NGA).

Both trials found that artesunate reduced egg excretion compared to placebo (Table 8), but the percent reduction was low compared to that seen in placebo controlled trials of praziquantel (percent egg reductions of between 52% and 69%).

The trial at unclear risk of bias also reported improved reductions in haematuria and proteinuria compared to placebo, while the trial at low risk of bias (Borrmann 2001 GAB) found no effect on proteinuria (see Appendix 3). No differences in adverse events were reported (see Appendix 5, Analysis 11.3).

Praziquantel versus artesunate (comparison 12)

The results of the three trials are inconsistent, with the single trial at low risk of bias finding only a modest reduction in egg excretion with artesunate.

Three trials (Borrmann 2001 GAB; Inyang Etoh 2009 NGA; Keiser 2010 CIV) compared artesunate 4 mg/kg/d for three days with praziquantel 40 mg/kg single dose.

The three trials had mixed results. In two trials artesunate performed poorly, with parasitological treatment failures of over 70% at one month and two months respectively (Borrmann 2001 GAB; Keiser 2010 CIV). In these trials praziquantel was clearly superior (Analysis 12.1). In the third trial (Inyang Etoh 2009 NGA), at unclear risk of bias due to inadequate description of trial methods, artesunate performed similarly to praziquantel with 28% treatment failures at two months (Analysis 12.1).

The percent egg reduction with artesunate varied across the three trials from 52% to 85% (see Appendix 2). In the single trial where both praziquantel and artesunate performed well at reducing treatment failures, both drugs had fairly modest effects on egg excretion (Inyang Etoh 2009 NGA).

Only the trial at unclear risk of bias (Inyang Etoh 2009 NGA) reported substantial effects of artesunate on haematuria and proteinuria (see Appendix 3). In the trial at low risk of bias (Borrmann 2001 GAB) praziquantel was clearly superior at reducing microhematuria (RR 0.43, 95% CI 0.3 to 0.62; 178 participants, one trial, Analysis 12.2).

All trials reported on adverse events with no significant differences noted between groups (see Appendix 5, Analysis 12.3).

Praziquantel versus praziquantel plus artesunate (comparison 13)

The results of the two trials were inconsistent but the trial at low risk of bias found no benefit with adding artesunate to praziquantel.

Two of the trials comparing artesunate with praziquantel also had a treatment arm where patients received both drugs (Borrmann 2001 GAB; Inyang Etoh 2009 NGA). Again, in the trial at low risk of bias (Borrmann 2001 GAB) adding artesunate to praziquantel did not substantially reduce treatment failures or percent egg reduction at eight weeks compared to praziquantel alone, whereas in the trial at unclear risk of bias (Inyang Etoh 2009 NGA), adding artesunate improved outcomes (Analysis 13.1; Table 9; Appendix 2). No differences in adverse events were reported (see Appendix 5).

Section E: Others

Mefloquine versus sulfadoxine-pyrimethamine (comparison 14)

In a single trial comparing the use of mefloquine and sulfadoxine-pyrimethamine as intermittent preventive treatment for malaria in pregnancy, a re-analysis of the small number of mothers infected with S. haemataobium found more women were cured at one month after mefloquine compared to sulfadoxine-pyrimethamine (RR 0.57, 95% CI 0.4 to 0.83; 44 participants, one trial, Analysis 14.1), and an egg reduction of 80% four weeks after treatment and 98% ten weeks after treatment (see Appendix 2).
Praziquantel versus mefloquine alone or mefloquine in combination with artesunate (comparison 15 and 16)

A single small trial (Keiser 2010 CIV) reported lower treatment failures with praziquantel 40 mg/kg alone than with mefloquine 25 mg/kg (RR 0.15, 95% CI 0.05 to 0.43; 45 participants, one trial, Analysis 15.1) or with mefloquine in combination with artesunate 4 mg/kg/d for three days (RR 0.23, 95% CI 0.07 to 0.74; 44 participants, one trial, Analysis 16.1). At four weeks, this trial reports a percent egg reduction of 74% at four weeks with mefloquine alone (19 participants), 96% with mefloquine and artesunate combined, and 97% with praziquantel (Appendix 2).

Keiser 2010 CIV recorded adverse events by active, prospective surveillance. Adverse events were mild to moderate and common in all groups. There were no statistically significant differences in any individual adverse event (Appendix 3).

Praziquantel versus praziquantel and albendazole (comparison 17)

One trial (Olds 1999 KEN) compared a single dose of praziquantel 40 mg/kg with a combination of single dose praziquantel 40 mg/kg plus albendazole 400 mg at day 45 (RR 0.9, 95% CI 0.62 to 1.3; 193 participants, one trial, Analysis 17.1). The authors concluded that albendazole does not influence the effect of praziquantel.

Adverse events were monitored by active, prospective surveillance and described as mild and transient. Diarrhoea, headache and abdominal pain were observed most frequently, but adverse events were reported for participants treated for *S. haematobium* and *S. mansoni* together (Appendix 5).

**DISCUSSION**

For a summary of the main results of the review and GRADE assessment of the quality of evidence see: Summary of findings for the main comparison; Summary of findings table 2; Summary of findings 2; Summary of findings 3; Summary of findings 4; Summary of findings 5; and Summary of findings 6.

**Summary of main results**

On average, a single 40 mg/kg dose of praziquantel reduced the proportion of people still excreting *S. haematobium* eggs in their urine by around 60% compared to placebo at one to two months after treatment (high quality evidence), and reduced the mean number of schistosome eggs in the urine by over 95% in five out of six trials (high quality evidence). Splitting praziquantel 40 mg/kg into two doses over 12 hours probably has no benefits over a single dose.

Two small trials compared a single 40 mg/kg dose of praziquantel with two or three doses of 10 mg/kg metrifonate and found no differences in cure. In one trial both drugs performed badly and in one trial both performed well.

Three trials evaluated the antimalarial artesunate, and two trials evaluated mefloquine, with inconsistent results.

**Overall completeness and applicability of evidence**

The WHO currently recommend that schistosomiasis is treated with a single dose of praziquantel of at least 40 mg/kg (*WHO 2006*). In this review we found no trials evaluating doses higher than 40 mg in urinary schistosomiasis, but doses of 40 mg/kg or even 30 mg/kg are effective at reducing egg excretion and achieving cure.

Of all the drugs that have been evaluated for treating urinary schistosomiasis, praziquantel has by far the strongest evidence base. It has been evaluated across a wide range of endemic countries, and most trials were conducted in children who bear the highest burden of disease. However, few trials included children younger than five years of age, and Stothard 2013 suggested that higher doses of praziquantel might be required for this group. We would have liked to explore this possibility through an analysis stratified by age, but the data did not allow this and no firm conclusions can be made. In addition, most trials concentrated on parasitological efficacy, and few reported clinical outcomes such as improvement in haematuria or anaemia. Data on resolution of long-term morbidity after treatment, as nutritional outcomes and sonographic findings are very rare, and follow-up is limited to less than one year.

The absolute proportion of people cured by praziquantel varied between trials while percent egg reduction was relatively homogenous. This may be explained by low sensitivity and negative predictive value of the diagnostic test, compounded with the fact that egg yield varies during the day and with physical activity. This means that patients with few eggs in their urine may be variably declared as positive or negative in different settings. The proportional reduction in the mean egg counts from before to after treatment is less prone to this error. It also appears that some trials based post-treatment egg reduction on the whole trial population (including cured patients with zero egg counts), while other trials based the post-treatment calculations on those patients still excreting eggs. We were unable to combine egg reduction values in meta-analysis, and assess statistical significance, due to the poor reporting of standard deviations and methods for calculating the mean (Table 2).

None of the included trials suggested drug resistance as a possible cause of high parasitological failure, or of recurrent schistosomiasis over prolonged follow-up. In high transmission areas two mechanisms could explain rising parasitological failure over time: maturation of immature worms (which escape the action of praziquantel) to egg producing adults, and reinfection.

Previously the WHO also recommended metrifonate at 7.5 mg/kg for three doses (given two weeks apart), but this drug is now largely unavailable (*Danso-Appiah 2008*). We found some evidence that repeated doses of metrifonate had reasonable anthischistosomal effects but we found no trials directly comparing this dose with the standard dose of praziquantel. Combining praziquantel with metrifonate is one possible strategy for improving parasitological cure as they attack *S. haematobium* by different mechanisms (*Utzinger 2004*). However, we only found one small trial evaluating a combination approach and this used a low dose of praziquantel rather than the standard 40 mg/kg (*Wilkins 1987 GMB*).

Antimalarials (such as artesunate and mefloquine) given alone or in combination with praziquantel are another potential future treatment option, but the current evidence base is limited to a few trials with inconsistent results. As many locations in sub-Saharan Africa are co-endemic for schistosomiasis and malaria, there are also concerns about development of *Plasmodium* parasite resistance to artemisinins, especially as they would be used in a single dose and without a companion antimalarial drug (*Utzinger...*).
2004). Any change in policy would need to fully consider this potential public health harm.

Quality of the evidence

We used the GRADE approach to assess the quality for the evidence.

We consider the evidence for substantial benefits with praziquantel compared to placebo to be of high quality, meaning we have confidence in this result. Many of the included trials are old, but reassuringly the findings of the most recent trial conducted in 2005/2006 are consistent with the older studies.

However, we consider most of the evidence for other comparisons in this review to be of low or even very low quality. Most of the trials evaluating metrifonate are old and precede guidelines on transparent reporting of clinical trials. As such, many trials lacked adequate descriptions of methods to allow judgements on risk of bias, and so risk of bias has been classified as unclear. Trials were also generally small and underpowered to reliably detect or exclude effects.

Of the three trials reporting on the antischistosomal effects of artesunate, only one was at low risk of bias and this trial found little effect with artesunate compared to placebo (Borrmann 2001 GAB). Although the metaanalysis suggests artesunate may improve cure when added to praziquantel, this evidence was of low quality due to inconsistency between trials, and the single trial showing a large effect being at unclear risk of bias for all domains.

Potential biases in the review process

Our information specialist followed a detailed, reproducible search strategy, and we searched reference lists of included trials. However, some trials might not be available online, and therefore an electronic search will not identify them.

In many cases, clarification of information with authors was not possible as no contact e-mail addresses were available as the trials were very old.

Agreements and disagreements with other studies or reviews

Two recent systematic reviews evaluated the use of artemisinins in treating urinary schistosomiasis (Liu 2011; Pérez del Villar 2012), and both concluded that the combination of artesunate plus praziquantel is superior to praziquantel alone. We find some evidence to support this we conclude that this evidence is only of low quality and encourage further high quality and adequately powered trials before any change in treatment policy. Of note, the trial at lowest risk of bias (Borrmann 2001 GAB), found no significant difference in cure between artesunate alone and placebo, or between praziquantel plus artesunate and praziquantel alone.

One further systematic review evaluated single or repeated doses of praziquantel, and found no evidence of benefit with repeated dosing compared to a single dose in people with S. haematobium infection (King 2011). We would agree that repeating doses two or three weeks apart does not seem to provide benefit over a single dose based on two trials with 686 participants. However, repeating doses at three monthly intervals over two years did seem to provide some additional benefits in a single small trial and further trials could evaluate this.

AUTHORS’ CONCLUSIONS

Implications for practice

Praziquantel is the most studied drug for treating urinary schistosomiasis and has the strongest evidence base. Although there is some evidence that 30 mg/kg may be sufficient, operationally this would prove difficult as 40 mg/kg is used to treat people with intestinal schistosomiasis, and the two diseases often overlap.

Implications for research

Potential strategies to improve future treatments for schistosomiasis include the combination of praziquantel with metrifonate, or with antimalarials with antischistosomal properties such as artesunate and mefloquine. Evaluation of these combinations requires rigorous, adequately powered trials using standardized outcome measures. It is both important and urgent that these parameters be agreed upon and applied. Trial protocols with standardised diagnostic methods, time points of follow-up and efficacy outcomes would enable us to combine trials in meta-analysis and to reduce heterogeneity between trials.

ACKNOWLEDGEMENTS

We would like to thank the authors of the previous version of this review Anthony Danso-Appiah, Jürg Utzinger, and Jianping Liu, who stood down for this update.

We thank the trial authors for their research, which enabled us to conduct a systematic review and particularly trial authors that responded to our requests for further information. We acknowledge Paul Garner for his expertise, experience and encouragement; Anne Marie Stephani, whose ready technical assistance with Review Manager (RevMan) was most helpful; and to Vittoria Lutje for her approachability and support. The editorial base of the Cochrane Infectious Diseases Group is funded by the UK Department for International Development for the benefit of developing countries.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Abden Abdi 1989 SOM

Methods
RCT

Diagnostics: egg excretion in a single, mid-day urine sample, mixing an aliquot of 10 mL urine, filtration (nucleopore)

Follow-up at 1, 2, 3 and 6 months

Participants
Children aged 11 to 12 years on average

Number randomized 300

Number analysed for primary outcome at one month 201, at six months 139

Inclusion criteria: excreting 20 or more S. haematobium eggs per 10 mL urine

Exclusion criteria: concomitant disease

Interventions
1. Metrifonate 3 x 7.5 mg/kg dose interval two weeks
2. Metrifonate 3 x 5 mg/kg within one day
3. Placebo

Drugs for treating urinary schistosomiasis (Review)

### Abden Abdi 1989 SOM (Continued)

| Outcomes          | Cure rate                                      |
|-------------------|-----------------------------------------------|
|                   | Percentage egg reduction                      |
|                   | Adverse events                                 |

| Notes             | Location: Somalia, southern part               |
|-------------------|-----------------------------------------------|
|                   | Setting: rural, five villages                  |
|                   | Endemicity: high                              |
|                   | Dates: not stated                              |
|                   | Source of funding: SAREC (Swedish agency for research cooperation with developing countries) |
|                   | Authors' conclusion: Both metrifonate regimens have similar efficacy |

**Risk of bias**

| Bias                                               | Authors' judgement | Support for judgement                                      |
|----------------------------------------------------|--------------------|------------------------------------------------------------|
| Random sequence generation (selection bias)        | Low risk           | Randomized, randomly assigned, table of random numbers.    |
| Allocation concealment (selection bias)            | Low risk           | All doses were kept in coded envelopes.                    |
| Blinding of participants and personnel (performance bias) | Low risk           | Double blind, placebo controlled "and the distributor of the drug and the participants were all blind to the type of treatment." |
| Blinding of outcome assessment (detection bias)     | Low risk           | Blinding of the lab technician.                            |
| Incomplete outcome data (attrition bias)           | High risk          | High loss to follow-up, 33% at one month, 53% at six months, balanced between treatment arms |
| Selective reporting (reporting bias)               | Low risk           | No evidence of selective reporting.                        |
| Other bias                                         | Low risk           | No evidence of other bias.                                 |

### Al Aska 1990 SAU

**Methods**

- RCT

  - Diagnostics: ova excretion in 10 mL midday urine after sedimentation
  - Follow-up: three and six months

**Participants**

- Adult patients referred to hospital, age not stated. Saudi and Jemeni
- Number randomized: not reported
- Number analysed: 100
Al Aska 1990 SAU (Continued)

Inclusion criteria: *S. haematobium* infection
Exclusion criteria: none stated
Co-infection with *S. mansoni*

| Interventions | Cure rates |
|---------------|------------|
| 1. Praziquantel 40 mg/kg single dose | |
| 2. Metrifonate 10 mg/kg three doses in intervals of two weeks | |

Outcomes

| Failure rates |

Notes

Location: Saudi Arabia
Setting: King Abdul Aziz University hospital, Riyadh. Patient referral
Endemity: not reported
Dates: not stated
Funding: not stated

Authors' conclusion: Metrifonate and praziquantel in the stated dosage are effective against *S. haematobium*, side effects are minor and transient

Risk of bias

| Bias | Authors' judgement | Support for judgement |
|------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk | "allocated randomly". |
| Allocation concealment (selection bias) | Unclear risk | Not mentioned. |
| Blinding of participants and personnel (performance bias) | Unclear risk | Not mentioned, no placebo mentioned. |
| Blinding of outcome assessment (detection bias) | Unclear risk | Not mentioned. |
| Incomplete outcome data (attrition bias) | Unclear risk | Loss to follow-up not reported. |
| Selective reporting (reporting bias) | Low risk | No evidence of selective reporting. |
| Other bias | Low risk | Few baseline characteristics reported. |

Basra 2012 GAB

Methods

RCT
Participants

Pregnant women attending ANC clinics, aged 19 to 25 years
Number randomized 65
Number analysed 44
Inclusion criteria: *S. haematobium* infection, pregnancy
Exclusion criteria: intake of antihelminthic and antimalarial drug within the previous two months, HIV pos

Interventions

1. Praziquantel 40 mg/kg single dose
2. Metrifonate 10 mg/kg two doses, dose interval two weeks

Outcomes

Cure rates
Failure rates
Egg counts at baseline, four and six weeks

Notes

Location: Gabon
Setting: two ANC health care centres
Endemicity: highly endemic for *S. haematobium* and malaria
Dates: Sept 2009 to Dec 2011
Funding: European and Developing Countries Clinical Trial Partnership (EDCCTP), Malaria in Pregnancy consortium, Karl Landsteiner Gesellschaft
Authors' conclusion: Mefloquine IPTp is effective against *S. haematobium* in pregnant women.

Risk of bias

| Bias                                           | Authors' judgement | Support for judgement |
|------------------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias)    | Low risk           | The randomizations list was computer-generated and provided by the independent MIPPAD trial management team. |
| Allocation concealment (selection bias)        | Low risk           | Trial assignment was concealed via sealed opaque envelopes which were opened only after enrolment of a patient by a trial investigator. |
| Blinding of participants and personnel (performance bias) | High risk          | Open-label. |
| Blinding of outcome assessment (detection bias) | Low risk           | Blinding of outcome assessors. |
| Incomplete outcome data (attrition bias)       | High risk          | High loss to follow-up, unbalanced (in the intervention group 18/48 = 37.5%, in the control group 3/48 = 6.25%) reasons partly stated. |
### Basra 2012 GAB (Continued)

| Selective reporting (reporting bias) | Low risk | No evidence of selective outcome reporting. |
|-------------------------------------|----------|-------------------------------------------|
| Other bias                          | Low risk | No risk of other bias.                    |

### Befidi Mengue 1992 CMR

**Methods**
- RCT
  - Diagnostics: urine sample preserved with 5 mg sodium azide, sedimentation for one hour, examination of sediment, egg count
  - Follow-up: six months (as only time point)

**Participants**
- Male primary school students, aged six to 15 years
- Number randomized 653, 436 in groups of interest for this review
- Exclusion: heavy *S. haematobium* infections (> 499 eggs/10 mL)
- Inclusion: positive for *S. haematobium*

**Interventions**
- 1. Praziquantel 40 mg/kg single dose
- 2. Placebo

**Outcomes**
- Geometric mean egg counts
- Weight
- Height
- Height for age
- Weight for age
- Weight for height
- MUAC
- Triceps skinfold thickness
- Mean muscle mass
- Hb (reported in a separate publication Befidi Mengue 1993, see reference Befidi Mengue 1992 CMR with slightly higher numbers of participants: 771 randomized, 518 in treatment groups of interest of this review).

**Notes**
- Location: Cameroon, Eastern Province, Bertoua
- Setting: urban (capital city of Eastern province), primary school
- Endemicity: polyparasitism is common
- Dates: not reported
- Funding: USAID Cameroon health constraints to rural production project 1608 - 1408
- Authors' conclusion: only demonstrable effect of a single praziquantel treatment on MUAC
Befidi Mengue 1992 CMR (Continued)

| Bias                                                                 | Authors' judgement | Support for judgement                                                                 |
|---------------------------------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)                         | Unclear risk       | Randomly assigned, method not stated.                                                  |
| Allocation concealment (selection bias)                             | Unclear risk       | Not mentioned.                                                                         |
| Blinding of participants and personnel (performance bias)           | Low risk           | The placebo tablets were physically identical to the praziquantel tablets.             |
| Blinding of outcome assessment (detection bias)                     | Unclear risk       | Not stated.                                                                            |
| Incomplete outcome data (attrition bias)                            | Unclear risk       | Loss to follow-up unclear, as numbers followed up not reported.                        |
| Selective reporting (reporting bias)                                | Low risk           | No evidence for selective reporting.                                                   |
| Other bias                                                          | Low risk           | No evidence for other bias.                                                            |

Borrmann 2001 GAB

Methods

RCT
Diagnostics: two urine samples. filtration of 10 mL of urine through polycarbonate filters (Millipore), staining with Trypan blue
Follow-up at day 56 (as only time point)

Participants

School children aged six to 15 years
Participants randomized: 300
Inclusion: S. haematobium positive, asymptomatic S. haematobium infection
Exclusion: symptomatic schistosomiasis, recent schistosomiasis treatment, serious underlying disease, pregnancy or lactation, anaemia (Hb < 7 G/dL)

Interventions

1. Praziquantel 40 mg/kg single dose
2. Artesunate 4 mg/kg once daily for three days
3. Artesunate 4 mg/kg once daily for three days and praziquantel 40 mg/kg single dose
4. Placebo

Outcomes

Cure rates
Failure rates
Egg reduction rates
Microhaematuria
Cochrane Database of Systematic Reviews

Borrmann 2001 GAB (Continued)

(Adverse events day seven)

Notes
Location: Gabon, province Moyen Ogone
Setting: rural villages
Endemicity: high (prevalence 80% in school children)
Dates: Oct. 2000 to Feb 2001
Funding: tablet donation Sanofi (Artesunate), Medochemie (Praziquantel)
Authors’ conclusions: Efficacy of artemesunate for S. haematobium treatment as single medication or in combination is low.

Risk of bias

| Bias                                       | Authors’ judgement | Support for judgement                                                                 |
|--------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | The randomization code was generated by computer.                                      |
| Allocation concealment (selection bias)    | Low risk           | The trial drugs were prepared in plastic bags, which were labelled sequentially with treatment numbers according to the randomization code. |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk           | Double blind. Praziquantel placebo and artemesunate placebo were identical in appearance to the respective active substance tablets. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                                                         |
| Incomplete outcome data (attrition bias) All outcomes | Low risk           | Low loss to follow-up (7.6%).                                                          |
| Selective reporting (reporting bias)       | Unclear risk       | Haemoglobin measurements, proteinuria and leucocyturia at day 56 not reported.          |
| Other bias                                 | Low risk           | No evidence for other bias.                                                             |

Davis 1981 ZMB

Methods
RCT
Diagnostics: three successive daily schistosome egg counts made on a random 10 mL urine sub sample of the total bladder content by a filtration staining technique; quantitative hatching technique (enumeration of miracidia, recently dead eggs and black eggs)
Follow-up: three consecutive daily urine samples, quantitative hatching test
Follow-up: at 1, 3, 7, 12 and 24 months

Participants
School children aged seven to 17 years
Number followed up after one month 151, number randomized not reported
Inclusion: S. haematobium positive
Exclusion: pregnant or lactating women, no serious acute coexistent diseases or complications, no other treatment during the past six months, older than six years

Interventions
1. Praziquantel 30 mg/kg single dose
2. Praziquantel 40 mg/kg single dose
3. Praziquantel 20 mg/kg 2 x daily

Outcomes
Cure rate
Failure rate

Notes
Location: Zambia, Ndola
Setting: eight rural schools
Dates: not reported
Endemicity: high
Funding: Parasitic Disease Programme for Research and Training in Tropical diseases
Authors' conclusion: treatment groups clinically and statistically comparable

Risk of bias

| Bias                                         | Authors' judgement | Support for judgement                                      |
|----------------------------------------------|--------------------|------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | Randomly assigned, random number table.                    |
| Allocation concealment (selection bias)     | Unclear risk       | Not mentioned.                                             |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk           | Single blind technique.                                    |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                             |
| Incomplete outcome data (attrition bias) All outcomes | Low risk           | Low loss to follow-up (3.7% to 6%) at 1, 3 and 7 months.  |
| Selective reporting (reporting bias)        | Low risk           | No evidence of selective reporting (some investigations at baseline not report-ed). |
| Other bias                                  | Low risk           | No evidence of other bias.                                 |

Davis 1981 ZMB (Continued)

Methods
RCT
Diagnoses: urine collection after 250 mL soda drink at midday. Trypan blue staining technique (if the egg concentration was less than 10 eggs per 10 mL urine, the whole volume (up to 350 mL) was filtered).

Follow-up one and five months

Participants

Male primary school children aged six to 11 years

Patients randomized 160, participants randomized into treatment groups of interest for this review: 107

Inclusion: co-infection with S. haematobium and S. mansoni

Exclusion: not reported

Interventions

1. Praziquantel 40 mg/kg single dose
2. Metrifonate 2 x 10 mg/kg, dose interval 14 weeks
3. Oxamnique 60 mg/kg single dose
4. Multivitamin single dose

Outcomes

Failure
Egg count

Notes

Location: Sudan Gezira
Setting: rural, village primary schools
Funding: Science and Technology for Development, EC, WHO, UNDP, World bank, Special Programme for Training & Research. Gesellschaft für technische Zusammenarbeit
Dates: not reported
Endemicity: high for both S. mansoni and S. haematobium

Authors' conclusion: discussion of correlation of parasitological outcomes and CAA titles

Risk of bias

| Bias                                      | Authors' judgement | Support for judgement                  |
|-------------------------------------------|--------------------|----------------------------------------|
| Random sequence generation (selection bias) | Unclear risk       | "randomly divided".                    |
| Allocation concealment (selection bias)   | Unclear risk       | Not mentioned.                         |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk       | Multivitamin as placebo, but blinding not mentioned. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                         |
| Incomplete outcome data (attrition bias)  | High risk          | Loss to follow-up high, at one months up to 23%, at five months up to 28%. |
**de Jonge 1990 SDN (Continued)**

**All outcomes**

| Selective reporting (reporting bias) | Low risk | No evidence for selective reporting. |
|--------------------------------------|----------|-------------------------------------|
| Other bias                           | Low risk | No evidence for other bias.         |

**Methods**

- **RCT**

  Diagnostics: collection of two urine samples at midday (12.00 to 14.00) after exercise on two consecutive days, agitation of urine sample, preservation of eggs, staining (1% aqueous solution, carbol fuchsin), filtration, egg counts

  Follow-up at eight weeks (as only time point)

**Participants**

- School children aged four to 20 years (nursery school, primary and junior secondary schools, students)

  Number randomized 260 children into five groups

  Inclusion: healthy, able to swallow the medication

  Exclusion: serious underlying disease, recent treatment for schistosomiasis, > 20 yrs, < 4 yrs old

**Interventions**

1. Praziquantel 40 mg/kg single dose and placebo
2. Praziquantel 40 mg/kg single dose only
3. Artesunate 4 mg/kg 1 x daily for three days and placebo
4. Artesunate 4 mg/kg 1 x daily for three days only
5. Praziquantel 40 mg/kg single dose and artesunate 4 mg/kg 1 x daily for three days
6. Placebo and placebo

**Outcomes**

- Cure

  Egg counts and egg reduction rate

  Haematuria

  Proteinuria

**Notes**

- Location: Nigeria, Adim community, Cross River State

  Setting: school students

  Dates: August 2005 to June 2006

  Endemicity: seasonal transmission

  Funding: partly funded by the management of the University of Calabar

  Authors' conclusion: both praziquantel and artesunate in the stated doses are safe, well-tolerated and effective in the trial area. Combined treatment is more effective and single treatment with any of the drugs.

---

| Other bias                                                          | Low risk           | No evidence of other bias.                  |

**Jewsbury 1976 ZWE**

**Methods**

RCT  
Diagnostics: three urine samples on three consecutive days, determination of egg counts and cure rates  
Follow-up at week 11 and week 36

**Participants**

Children, aged three to 15 years (and older)  
Number of children randomized: 179  
Number of children analysed 114 (complete case analysis)  
Inclusion: S. haematobium positive  
Exclusion: not reported

**Interventions**

1. Metrifonate 7.5 mg x 3, dose interval two weeks  
2. Control: no intervention

**Outcomes**

Cure rate  
Failure rate  
Median urine egg counts

**Notes**

Location: Zimbabwe near Salisbury  
Setting: rural, four farms  
Dates: not reported
Jewsbury 1976 ZWE (Continued)

Endemicity: high (pre-infection rate with *S. haematobium* 80%)

Funding: Drug donation by Bayer

Authors’ conclusion: Metrifonate is safe and effective for the treatment of *S. haematobium*

### Risk of bias

| Bias                              | Authors' judgement | Support for judgement |
|-----------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk | "randomised". |
| Allocation concealment (selection bias) | Unclear risk | Not mentioned. |
| Blinding of participants and personnel (performance bias) | Unclear risk | Not mentioned. |
| All outcomes                      |                    |                       |
| Blinding of outcome assessment (detection bias) | Unclear risk | Not mentioned. |
| All outcomes                      |                    |                       |
| Incomplete outcome data (attrition bias) | High risk | Participant numbers not reported at week 11, high loss to follow-up of 46% at week 36. |
| All outcomes                      |                    |                       |
| Selective reporting (reporting bias) | Unclear risk | Data of week 11 not reported. |
| Other bias                        | High risk          | Baseline imbalance; for the infected, untreated control group, an infection rate of 89.4% is given at baseline. |

Kardaman 1985 SDN

**Methods**

RCT

Diagnostics: centrifugation, sediment taken for egg counts

Follow-up at five weeks and three months

**Participants**

School children aged seven to 11 years

Number of children included: 237

Inclusion: co-infection *S. haematobium* and *S. mansoni*

Exclusion: receiving medication for any other infection, treatment for schistosomiasis during the preceding 6 months.

**Interventions**

1. Praziquantel 40 mg/kg single dose

2. Praziquantel 2 x 20 mg/kg in one day, dose interval four to six hours

**Outcomes**

Cure

Failure
### Kardaman 1985 SDN (Continued)

#### Adverse events

| Notes |
|-------|
| Location: Sudan, Galaga Village |
| Setting: rural, primary schools |
| Dates: not reported |
| Endemicity: high (mixed infections common) |
| Funding: Parasitic disease programme, WHO |
| Authors' conclusion: Results of two regimens not significantly different. Treatment for this setting has to be repeated every six months. |

### Risk of bias

| Bias                                      | Authors' judgement | Support for judgement |
|-------------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk       | Randomly assigned.    |
| Allocation concealment (selection bias)   | Unclear risk       | Not mentioned.        |
| Blinding of participants and personnel (performance bias) | Unclear risk       | Not mentioned.        |
| Blinding of outcome assessment (detection bias) | Unclear risk       | Not mentioned.        |
| Incomplete outcome data (attrition bias)  | Low risk           | Loss to follow-up at five weeks up to 4.7%, at three months up to 8.4%. |
| Selective reporting (reporting bias)      | Low risk           | No evidence for selective reporting. |
| Other bias                                | Low risk           | No evidence for other bias. |

### Keiser 2010 CIV

#### Methods

- RCT
  - Diagnostics: collection of two urine specimen at midday (10.00 to 14.00), samples were rigorously shaken, filtration of 10 mL through a 13 mL filter with 25 μm diameter
  - Follow-up at 26 days

#### Participants

- School children aged eight to 12 years
- Participants randomized 83
- Inclusion: confirmed *S. haematobium* infection
**Keiser 2010 CIV** (Continued)

Exclusion: not reported

| Interventions |               |
|---------------|---------------|
| 1. Praziquantel 40 mg/kg single dose |
| 2. Mefloquine 25 mg/kg single dose |
| 3. Artesunate 4 mg/kg 1 x daily for three days |
| 4. Artesunate 3 x 100 mg and mefloquine 250 mg |

| Outcomes        |               |
|-----------------|---------------|
| Cure rates      |               |
| Failure rate    |               |
| Egg count       |               |
| Egg reduction rate |            |
| Adverse effects |               |

| Notes |               |
|-------|---------------|
| Location: Côte d’Ivoire, district Agboville |
| Setting: rural, school children |
| Dates: November to December 2009 |
| Funding: support Dafra Pharma, Mepha for drug donations |
| Endemicity: highly endemic, 40% among school children |
| Authors’ conclusion: High cure rates with praziquantel, promising results for mefloquine - artemisinin (in the standard dose for malaria) |

**Risk of bias**

| Bias                                      | Authors’ judgement | Support for judgement |
|-------------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk       | "using a computer generated randomisation code". Seven children were added to one treatment group in a non-randomized manner. |
| Allocation concealment (selection bias)   | High risk          | Not implemented (email correspondence with author). |
| Blinding of participants and personnel (performance bias) All outcomes | High risk          | Open label. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned. |
| Incomplete outcome data (attrition bias) All outcomes | Low risk           | No loss to follow-up during the trial (day 26). |
| Selective reporting (reporting bias)     | Low risk           | Urinary findings day 26 not reported (not available, email correspondence with author). |

Other bias | Low risk | No evidence of other sources of bias.
**King 1989 KEN**

**Methods**

RCT  
Diagnostics: collection of midday urine sample (10.00 to 13.00), urine filtration technique with nucleopore filters, egg count  
Follow-up at two to three months

**Participants**

Primary school students aged five to 17 years and adult participants over 20 years  
Number of patients randomized 280 (34 adults, 246 children)  
Inclusion: egg count > 50 eggs/10 mL urine  
Exclusion: not reported

**Interventions**

1. Praziquantel 10 mg/kg single dose  
2. Praziquantel 20 mg/kg single dose  
3. Praziquantel 30 mg/kg single dose  
4. Praziquantel 40 mg/kg single dose

**Outcomes**

Cure  
Egg counts  
Severity of infection  
Proteinuria  
Haematuria

**Notes**

Location: Kenya, Kwale district  
Setting: rural, primary schools  
Dates: not reported  
Endemicity: high  
Funding: Edna McConnell Clark Foundation  
Authors’ conclusion: low dose (20 mg/kg) is as effective as standard dose (40 mg/kg) of praziquantel (reductions in parasite burden and morbidity) for population based control programmes

**Risk of bias**

| Bias                                | Authors’ judgement | Support for judgement |
|-------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Low risk | Random allocation, pre-randomized cards. |
| Allocation concealment (selection bias) | Unclear risk | Not mentioned. |
| Blinding of participants and personnel (performance bias) | High risk | Clinicians not blinded to the intervention. |
| All outcomes                        |                    |                       |

### King 2002 KEN

#### Methods

| Details | Description |
|---------|-------------|
| RCT     | Diagnostics: Collection of two mid-day (10:00 to 14:00) on different days, filtration, Nucleopore) Intensity of infection assigned according to the highest one day egg count in the repeated daily testing.  
Follow-up at six weeks and nine months |

#### Participants

| Details | Description |
|---------|-------------|
| School children and adults, aged four to 23 years | Number of participants randomized 291  
Inclusion: *S. haematobium* positive  
Exclusion: not reported |

#### Interventions

| Details | Description |
|---------|-------------|
| 1. Praziquantel 40 mg/kg single dose  
2. Praziquantel 20 mg/kg single dose | |

#### Outcomes

| Details | Description |
|---------|-------------|
| Cure  
Egg count  
Ultrasound findings (Hydronephrosis, bladder thickening and bladder irregularity) | |

#### Notes

| Details | Description |
|---------|-------------|
| Location: Kenya, Coastal Province, Kwale District  
Setting: rural, village schools  
Dates: 1992 to 1993  
Endemicity: high  
Funding: WHO, TDR, Rockefeller Foundation Joint Funding Venture and National Institutes of Health | |
Authors' conclusion: Praziquantel 20 mg and praziquantel 40 mg are equally effective in reducing structural urinary tract morbidity over nine months. A praziquantel dose of 20 mg/kg may be sufficient for practical control of renal and bladder morbidity due to S. haematobium in certain settings: not reported (trial might be underpowered for ultrasound findings).

**Risk of bias**

| Bias                                      | Authors' judgement | Support for judgement                                                                 |
|-------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | "Infected students were then individually randomised to therapy...by computer random number generation." |
| Allocation concealment (selection bias)   | High risk          | Allocation was not concealed.                                                          |
| Blinding of participants and personnel (performance bias) | High risk            | No blinding of personnel: "Dosing assignment lists were transmitted to clinical staff responsible for treatment". |
| Blinding of outcome assessment (detection bias) | Low risk            | Blinding of outcome assessors (clinicians, parasitologists). "Assignments were masked form staff parasitologists and physicians responsible for follow-up until the end of the study." |
| Incomplete outcome data (attrition bias)  | High risk          | Loss to follow-up 31% at six weeks.                                                   |
| Selective reporting (reporting bias)      | Low risk           | No evidence of selective outcome reporting.                                            |
| Other bias                                | Low risk           | Important baseline characteristics (egg counts) not reported at baseline.              |

**McMahon 1979 TZA**

**Methods**

RCT

Diagnostics: Collection of three midday (10.00 to 13.00) urine samples on three consecutive days, sedimentation in a conical flask for 30 mins, taking of a 10 mL sample of the bottom of the flask, centrifugation and processing of the deposit 5 mL boiled, cooled water added to deposit, miracidia hatching test, fixing and staining of miracidia (alcohol and eosin), microscopy and count.

Follow-up at one, three and six months.

**Participants**

School children aged seven to 15 years

No. of children randomized: 138

Inclusion: S. haematobium positive

Exclusion: not reported

**Interventions**

1. Praziquantel 30 mg/kg single dose

2. Praziquantel 40 mg/kg single dose
McMahon 1979 TZA (Continued)

3. Praziquantel 2 x 20 mg in one day, dose interval four hours
4. Placebo

Outcomes
- Cure
- Egg counts
- Adverse effects

Notes
- Location: Tanzania, Tanga region
- Setting: school, rural area
- Endemicity: high, transmission may vary greatly from year to year and season to season.
- Dates: not reported
- Funding: MRC/WHO/Tanzania Helminthiasis Research Unit, Tanga

Authors’ conclusion: Praziquantel in the given doses is not toxic. Praziquantel 40 mg did not affect the therapeutic response in children with large egg loads.

As cure rates are influenced by pre-treatment egg loads, trials of higher doses in patients with high egg loads needed.

Risk of bias

| Bias                                   | Authors’ judgement | Support for judgement                                      |
|----------------------------------------|--------------------|------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | Randomly sub-divided into four groups according to previously arranged blocks. |
| Allocation concealment (selection bias)  | Unclear risk       | Not mentioned.                                             |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk | Not mentioned.                                             |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                             |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk       | Loss to follow-up 10% to 15% at 1, 3 and 6 months.         |
| Selective reporting (reporting bias)    | Low risk           | No evidence of selective reporting.                         |
| Other bias                             | Low risk           | Baseline characteristics not reported.                     |

McMahon 1983 TZA

Methods
- RCT
McMahon 1983 TZA (Continued)

Diagnostics: collection of two midday (10.00 to 14.00) samples on two consecutive days for initial diagnosis, of three samples for follow-up, quantitative hatching technique, sedimentation of 10 mL urine

Follow-up at two and four months

Participants

School children and adults
Number of participants randomized: 90
Inclusion: 250 miracidia/10 mL urine
Exclusion: not reported

Interventions

1. Praziquantel 30 mg/kg single dose
2. Metrifonate 10 mg/kg 1 x daily, dose interval 14 days
3. Niridazole 25 mg/kg 1 x daily for six days, dose interval one day

Outcomes

Cure rates
Egg reduction rates
Adverse effects

Notes

Location: Tanzania, Tanga region
Setting: not stated
Endemicity: high
Dates: not reported
Funding: MRC/WHO/Tanzania Helminthiasis Research unit, Tanga, Biltricide (Praziquantel) was supplied by Bayer.

Authors conclusion: Praziquantel was more effective than metrifonate and niridazole. Side effects were minor.

| Bias                                      | Authors' judgement | Support for judgement                                      |
|-------------------------------------------|--------------------|------------------------------------------------------------|
| Random sequence generation (selection bias) | Unclear risk       | Randomly allocated.                                         |
| Allocation concealment (selection bias)   | Unclear risk       | Not mentioned.                                              |
| Blinding of participants and personnel (performance bias) All outcomes | High risk | Not mentioned; use of different regimens, no use of placebo. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk | Not mentioned.                                               |
| Incomplete outcome data (attrition bias) All outcomes | High risk | Loss to follow-up partly high, not balanced (at four months 0% in the praziquantel group, 26% in the metrifonate and 30% in the niridazole group.) |

|-------------------------------|--------------------|---------------------------------------|
| Selective reporting (reporting bias) | Unclear risk       | No evidence of selective reporting.   |
| Other bias                    | Low risk           | Few baseline characteristics reported.|

#### Risk of bias

| Bias                          | Authors’ judgement | Support for judgement                |
|-------------------------------|--------------------|---------------------------------------|
| Random sequence generation (selection bias) | Unclear risk       | Randomly assigned.                    |
| Allocation concealment (selection bias)       | Unclear risk       | Not mentioned.                        |
| Blinding of participants and personnel (performance bias) | Unclear risk       | Not mentioned.                        |

### Mott 1985 Ghana

Methods

RCT

Diagnostics: collection or one urine sample, two random samples out of this urine sample were processed. Quantitative urine filtration technique

Follow-up at three and six months

Participants

Residents "entire population of five settlements", aged six years or older

Number of people randomized 266

Inclusion: *S. haematobium* infected

Exclusion: pregnancy, alcoholism, severe debilitating disease

Interventions

1. Praziquantel 30 mg/kg single dose
2. Praziquantel 40 mg/kg single dose

Outcomes

Cure rate

Egg count, egg reduction rate

(Urinary results not reported by treatment group)

Notes

Location: Ghana, Lake Volta

Setting: rural, five settlements

Dates: not reported

Endemi city: not reported

Funding: Parasitic Diseases Programme WHO/UNDP/Wold bank/WHO Special Programme for Research and Training in Tropical Diseases

Authors’ conclusions: Similar efficacy of Praziquantel 30 mg and 40 mg in this trial. Praziquantel reduces clinical signs (macrohaematuria) and morbidity in urinary schistosomiasis
### Mott 1985 GHA (Continued)

| All outcomes | Blinding of outcome assessment (detection bias) | Unclear risk | Not mentioned. |
|--------------|-----------------------------------------------|--------------|----------------|
| All outcomes | Incomplete outcome data (attrition bias)       | Low risk     | Loss to follow-up at six months 11.6%. |
| All outcomes | Selective reporting (reporting bias)           | Low risk     | No evidence of selective reporting. |
| All outcomes | Other bias                                     | Low risk     | Baseline characteristics not reported per group. |

### Olds 1999 KEN

| Methods | RCT |
|---------|-----|
|         | Diagnostics: Eggs from 2 x 10 mL samples were filtered on membranes (Nucleopore) |
|         | Follow at 45 days, 90 days, six months and one year |

| Participants | School children aged four to 18 years |
|--------------|--------------------------------------|
| Number of participants pos for *S. haematobium*: 380 |
| Inclusion: *S. haematobium* positive |
| Exclusion: pregnancy or marriage, failure to submit two stool specimens prior to initial therapy, known allergy to praziquantel or albendazole, treatment within the past six months |

| Interventions | 1. Praziquantel 40 mg/kg single dose and albendazole 400 mg single dose |
|---------------|---------------------------------------------------------------------|
|               | 2. Praziquantel 40 mg/kg single dose and placebo |
|               | 3. Albendazole 400 mg single dose and placebo |
|               | 4. Placebo and placebo |

| Outcomes | Cure |
|----------|------|
|          | Egg count |
|          | Ultrasound |
|          | Weight, height, skinfold thickness, MUAC |
|          | Hb |
|          | Adverse effects |

| Notes | Location: Kenya, Kwale District, Coast province for *S. haematobium* (multi centre trial for different *Schistosoma* species, conducted in different countries) |
|-------|-------------------------------------------------------------------------------------------------------------------------------------|
|       | Setting: rural |
|       | Endemicity: endemic ascariasis, hookworm, trichuris, *S. haematobium* |
|       | Dates: not reported |
Funding: WHO/TDR Tropical disease research

Authors' conclusion: Combined mass treatment of children with albendazole and praziquantel produced not more side effects than treatment with praziquantel alone.

Combined mass treatment should have an important impact on schistosoma and hookworm prevalence and intensity and improves Hb levels.

### Risk of bias

| Bias                                           | Authors' judgement | Support for judgement                                                                 |
|------------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)    | Low risk           | Randomized in one of four treatment groups, block design with block size of 80.       |
| Allocation concealment (selection bias)        | Low risk           | Randomization lists were prepared by WHO/TDR using a randomized block design.         |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk           | Double blind, placebo controlled; physically identical placebo.                       |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                                                        |
| Incomplete outcome data (attrition bias) All outcomes | Low risk           | Loss to follow-up 10% at six months, loss to follow-up 17% at one year (for all groups). |
| Selective reporting (reporting bias)          | High risk          | Hb values, proteinuria, hematuria, ultrasound findings not reported.                   |
| Other bias                                     | Low risk           | No evidence for other bias.                                                           |

### Omer 1981 SDN

**Methods**

RCT

Diagnosis: sedimentation concentration technique, miracidial hatching

Follow-up at seven days, one month, three to four months, six months

**Participants**

Patients presenting to the Hospital of Tropical diseases, Karthoum, aged eight to 16 years

Number of patients randomized: 152

Inclusion: mixed *S. haematobium* and *S. mansoni* infections

Exclusion: under eight years of age, advanced stage of disease, severe anaemia, poor general health

**Interventions**

1. Praziquantel 30 mg/kg single dose
2. Praziquantel 40 mg/kg single dose
3. Praziquantel 2 x 20 mg/kg within one day

**Outcomes**

Cure rates
Egg counts
Adverse events
Laboratory parameters at day 0 or 1 and at day 1 or 2, not of interest for this review

Notes
Location: Sudan, Karthoum
Setting: Hospital of Tropical Diseases, Karthoum
Endemicity: not reported
Dates: 1978 to 1979
Funding: not reported
Authors' conclusion: Praziquantel is easily applicable, safe and effective in the treatment of mixed (S. haematobium and S. mansoni) infections

Risk of bias

| Bias                                | Authors' judgement | Support for judgement               |
|-------------------------------------|--------------------|-------------------------------------|
| Random sequence generation (selection bias) | Unclear risk      | Randomized.                         |
| Allocation concealment (selection bias) | Unclear risk      | Not mentioned.                      |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk      | Single blind.                       |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk      | Not mentioned.                      |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk      | Loss to follow-up at six months 17% to 22%, balanced. |
| Selective reporting (reporting bias) | Low risk           | No evidence of selective reporting.  |
| Other bias                          | Low risk           | No evidence of other bias.           |

Oyediran 1981 NGA

Methods
RCT
Diagnostics: collection of a midday urine sample (12.00 to 2.00), taking a 10 mL sub sample, filtration of the urine, staining with Ninhydrin, counting of the eggs retained on the filter paper
Follow-up at one, three and six months

Participants
Primary school children aged nine to 16 years
Participants randomized: 90
Oyediran 1981 NGA (Continued)

Inclusion criteria: mean egg count 80 eggs/10 mL, viable eggs, aged over six years

Exclusion criteria: under six years, concurrent acute or serious illness, antischistosomal treatment within the past six months

**Interventions**

- Praziquantel 30 mg/kg single dose
- Praziquantel 40 mg/kg single dose
- Praziquantel 2 x 20 mg/kg, dose interval three to four hours
- Placebo

**Outcomes**

- Egg counts

**Notes**

- Nigeria, Oyo State
- Setting: Primary Schools
- Dates: not reported
- Funding: not reported

Authors' conclusion: No significant difference in efficacy between the three dosage regimens, trials on the effects of lower doses required.

**Risk of bias**

| Bias                                      | Authors' judgement | Support for judgement                                                                 |
|-------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | Table of random numbers.                                                              |
| Allocation concealment (selection bias)   | Unclear risk       | Not mentioned.                                                                        |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk       | Placebo single dose                                                                  |
|                                           |                    | The treatment group received a split dose of praziquantel, blinding not mentioned.    |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                                                        |
| Incomplete outcome data (attrition bias) All outcomes | High risk          | High loss to follow-up, not balanced (at one month 4 to 17%, at three months 17 to 23%, at six months 26 to 38%, at twelve months 76% to 87%). |
| Selective reporting (reporting bias)      | Low risk           | No evidence of selective reporting.                                                    |
| Other bias                                | Low risk           | No evidence of other bias.                                                             |

Pugh 1983 MWI

**Methods**

RCT
Diagnostics: collection of two midday urine samples on two consecutive days filtration, staining and egg count
Follow-up at one, three and six months. Further follow-up reported at nine, 12, 15 and 24 months in a separate publication (Pugh 1983 MWI)

| Participants          | School children aged five to 18 years |
|-----------------------|---------------------------------------|
| Number of participants randomized: 499 |
| Inclusion: mean egg count (S. haematobium) > 19/10 mL |
| Exclusion: malaise, febrile illness, treatment with schistosomical drugs in the past six months |

| Interventions | 1. Praziquantel 40 mg/kg single dose |
|---------------|--------------------------------------|
|               | 2. Niridazole 25 mg/kg single dose and metrifonate 10 mg/kg single dose |
|               | 3. Mefronate 10 mg/kg single dose |
|               | 4. Niridazole 25 mg/kg single dose |
|               | 5. Placebo |

| Outcomes | Cure |
|----------|------|
|          | Geometric mean egg counts |
|          | Egg reduction rates |

| Notes | Location: Malawi, Pirimiti Area, Phalombe plain |
|-------|-------------------------------------------------|
|       | Setting: rural |
|       | Endemicity: seasonal |
|       | Funding: Overseas Development Administration, U.K. MoH Malawi. Praziquatel supplied by Bayer |
|       | Authors' conclusion: Praziquantel is superior to the other drugs studied in this trial, it is the most efficient and convenient drug available. Maintained low egg output at 24 months was presumably influenced by low levels of transmission during the second year of the trial, which was very dry. |

**Risk of bias**

| Bias                                | Authors' judgement | Support for judgement |
|-------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Low risk         | Use of a randomized x-y list. |
| Allocation concealment (selection bias) | Low risk         | "An independent worker had sole and confidential access to a randomised x-y list." |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk         | Described as double blind. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk     | Not mentioned. |
### Pugh 1983 MWI (Continued)

| Bias                                      | Authors' judgement | Support for judgement |
|-------------------------------------------|--------------------|-----------------------|
| Incomplete outcome data attrition bias All outcomes | Unclear risk       | Loss to follow-up low at one months: 0% to 4.1%, at three months 8% to 11% in treatment groups, up to 23% in the placebo group; at six months 20% in the treatment group. Loss to follow-up high at 24 months, about 40% to 70%. |
| Selective reporting bias                  | Low risk           | No evidence of selective reporting. |
| Other bias                                | High risk          | Baseline imbalance in terms of intensity of infection. "In accordance to with local ethical guidelines the placebo group consisted only of children with light (20-124 ova/10mL or moderate (125 to 4999 ova/10 mL) infections before treatment. Important baseline characteristics not reported (age, weight)." |

### Rey 1983 NER

| Methods | RCT |
|---------|-----|
| Diagnostics: collection of two urine samples, filtration (Swinex 13 Filter Millipore, 13 mm diameter), fixation and staining (Lugol), egg counts | |
| Length of follow-up: one, three and six months | |

| Participants | Participants: recruits aged 18 to 20 years and college students aged 15 to 19 years |
|--------------|----------------------------------------------------------------------------------|
| Number of participants randomized | 207 |
| (co-infection with S. mansoni likely, but not investigated) | |
| Inclusion: S. haematobium positive | |
| Exclusion: not reported | |

| Interventions | 1. Praziquantel 30 mg/kg daily dose |
|---------------|------------------------------------|
| 2. Praziquantel 40 mg/kg daily dose | |
| 3. Oltipraz 17.5 mg/kg 2 x daily in one day | |

| Outcomes | Failure |
|-------------------------------|---------|
| Egg reduction rates | |

| Notes | Location: Niger |
|-------|----------------|
| Setting: not reported | |
| Endemicity: not reported | |
| Dates: not reported | |
| Funding: not reported | |
| Authors' conclusion: No significant difference found between praziquantel 30 mg/kg and praziquantel 40 mg/kg. | |

| Allocation concealment (selection bias)          | Unclear risk       | No comment.                                                |
| Blinding of participants and personnel (performance bias) | Unclear risk       | No comment.                                                |
| Blinding of outcome assessment (detection bias)  | Unclear risk       | No comment.                                                |
| Incomplete outcome data (attrition bias)         | High risk          | Loss to follow-up high: at one month 50%, at four months 39% |
| Selective reporting (reporting bias)             | Low risk           | No evidence of selective reporting.                         |
| Other bias                                        | Low risk           | No evidence of other bias, funding not stated.              |

Sacko 2009 MLI

Methods

RCT

Diagnostics: Collection of three urine samples between 10 am and 2 PM on three consecutive days. 10 mL of urine passed through a nucleopore filter, Swinnex filter support. Egg counts.

Follow-up at 3, 6 and 18 months

Participants

School children aged seven to 14 years

Number of participants randomized: 603

Inclusion: not reported

Exclusion: not reported

Interventions

Praziquantel 40 mg/kg single dose

Praziquantel 40 mg/kg two doses, interval two weeks

Outcomes

Cure rate

Egg reduction

Haematuria
### Sacko 2009 MLI (Continued)

**Notes**
- Location: Mali, Niger River Basin
- Setting: rural, primary schools
- Endemicity: not reported
- Dates: not reported
- Funding: not reported

Authors' conclusion: Significantly reduced prevalence of microhematuria with praziquantel x 2, this could indicate reduction of morbidity

**Risk of bias**

| Bias                                           | Authors' judgement | Support for judgement                                                                 |
|-----------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)   | Low risk           | Randomized (SPSS generated random number tables).                                      |
| Allocation concealment (selection bias)       | Low risk           | Not mentioned.                                                                        |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk           | Double blind, placebo-controlled. Placebo tablets were of the same form and colour as praziquantel. |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                                                        |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk       | Loss to follow-up unclear, as number randomized were not reported, only the numbers at first follow-up at three months. |
| Selective reporting (reporting bias)          | Low risk           | Follow-up data at six and 18 months reported in graphs, not in numbers.                |
| Other bias                                    | Low risk           | No evidence for other bias.                                                            |

### Stephenson 1985 KEN

**Methods**
- RCT
- Diagnostics: nucleopore filter method of Peters and others

- collection of a midday urine sample (complete bladder content, 11.00 to 12.00) after 200 mL of fruit drink, nucleopore filter method of Peters and others, staining with 0.5 trypan blue, egg counts in 10 mL of urine adjusted for the total volume of each urine specimen
- Follow-up for six months

**Participants**
- Primary school children aged six to 16 years
- Number of participants randomized: 400
- Inclusion: light to moderate *S. haematobium* infections at exam 1
Excursion: not reported

Interventions

1. Metrifonate 7.5 mg/kg three doses, dose interval one to two weeks
2. Placebo: gelatin capsules

Outcomes

Parasitological failure and cure
Egg counts
Egg reduction rate
Haemoglobin
Anthropometric measures weight, height, weight for height, middle upper arm circumference, triceps and subscapular skinfold thickness
Liver size
Spleen size

Notes

Location: Kenya, Kwale District, Coast Province
Setting: rural, four primary schools
Endemicity: highly endemic
Dates: not reported
Funding: not reported

Authors' conclusion: S. haematobium infections can precipitate or aggravate anaemia in vulnerable children (poor iron intake, high endemicity of other parasites). S. haematobium treatment improves Hb levels.

S. haematobium treatment may improve child growth (in populations were hookworm infections and Protein Energy Malnutrition is common). S. haematobium treatment may be associated with regression of splenomegaly and hepatomegaly in children treated for S. haematobium infection. Population-based treatment is recommended.

Risk of bias

| Bias                                      | Authors' judgement | Support for judgement                                      |
|-------------------------------------------|--------------------|------------------------------------------------------------|
| Random sequence generation (selection bias) | Unclear risk       | Allocated at random.                                        |
| Allocation concealment (selection bias)    | Unclear risk       | Not described.                                              |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk           | Use of placebo.                                             |
| Blinding of outcome assessment (detection bias) All outcomes | Low risk           | Examinations 1 and 2 were carried out in a blind fashion with the same team of workers. |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk       | Loss to follow-up unclear, as results were reported as proportions. |
Selective reporting (reporting bias) | Low risk | No evidence of selective outcome reporting.
---|---|---
Other bias | Low risk | No evidence of other sources of bias.

**Stephenson 1989 KEN**

Methods
RCT

Diagnostics: collection of a midday urine sample (complete bladder content, 11.00 to 12.00) after 200 mL of fruit drink, nucleotide filter method of Peters and others, staining with 0.5 trypan blue, egg counts in 10 mL of urine adjusted for the total volume of each urine specimen

Follow-up at eight months (as only time point)

Latham 1990, a sub-study nested within Stephenson 1989 KEN, followed up patients at five weeks (as only time point)

Participants
Primary school children, 98% Muslim of the Wadigo tribe, aged eight to 13 years

Number of participants randomized: not reported

Number of participants analysed: 312

Inclusion: light to moderate infections

Exclusion: anaemia (Hb < 8 G/dL, severe infections)

Latham 1990 included 48 boys aged seven to 15 years with no sign of puberty, high egg counts, Hb > 8 G/dL, cooperation for physical fitness test

Interventions
1. Praziquantel 40 mg/kg single dose
2. Metrifonate 10 mg/kg single dose
3. Placebo

As a nested study, Latham had the same study arms.

Outcomes
Parasitological failure

Egg counts (geometric and arithmetic)

Anthropometric measurements: weight, height, MUAC, triceps skinfold thickness, subcapular skinfold thickness,

Haemoglobin

Liver size

Spleen size

Latham 1990 (reference see Stephenson 1989 KEN) reports parasitological failure, egg reduction rate and anthropometric measures: weight, height, skinfold thickness, MUAC at five weeks at five weeks, and additionally reports on

Physical fitness: Harvard Step test,

Appetite (quantity of porridge consumed)

Questionnaire of clinical symptoms
Notes
Location: Kenya, Kwale district, Coast Province
Setting: rural, primary schools
Endemicity: endemic for *S. haematobium*, hookworm and malaria
Dates: March 1986 to April 1986
Funding: Edna McConnell Clark Foundation, grant 284-0120

Authors’ conclusion: Both metrifonate and praziquantel are effective in reducing egg excretion and are both recommended for population based treatment. Praziquantel is more effective. *S. haematobium* treatment with a single dose of either metrifonate or praziquantel may improve child growth in areas were hookworms and malnutrition are common and appears to have a beneficial effect on hepatomegaly and splenomegaly.

Treatment of moderate to heavy *S. haematobium* infections with metrifonate or praziquantel in undernourished schoolboys can improve physical fitness, growth rates and appetite within approximately one month.

Recommendation for widespread population based chemotherapy in highly endemic areas as Kwale district.

### Risk of bias

| Bias                                      | Authors' judgement | Support for judgement               |
|-------------------------------------------|--------------------|--------------------------------------|
| Random sequence generation (selection bias) | Unclear risk       | Allocated at random.                 |
| Allocation concealment (selection bias)   | Unclear risk       | Not mentioned.                       |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk | Use of placebo.                     |
| Blinding of outcome assessment (detection bias) All outcomes | Low risk | Examinations carried out in a blind fashion. |
| Incomplete outcome data (attrition bias) All outcomes | Low risk | Loss to follow-up 10%, 3 participants not accounted for. |
| Selective reporting (reporting bias)      | Low risk           | No evidence of selective reporting.  |
| Other bias                                | Low risk           | No evidence for other source of bias. |

### Taylor 1988 ZWE

Methods
RCT

Diagnostics: urine sample collection; three midday urine samples (10.00 to 14.00), filtration (13 mm nytrel filter), staining with Lugol
### Taylor 1988 ZWE (Continued)

| Follow-up at 1, 3 and 6 months |
|-------------------------------|

### Participants
- School children aged ten to 15 years, mixed infection with *S. haematobium* and *S. mansoni*
- Number of participants randomized: 373
- Inclusion: mixed *S. haematobium* and *S. mansoni* infection
- Exclusion: not reported

### Interventions
1. Praziquantel 10 mg/kg single dose
2. Praziquantel 20 mg/kg single dose
3. Praziquantel 30 mg/kg single dose
4. Praziquantel 40 mg/kg single dose
4. Control: Nil

### Outcomes
- Parasitological cure
- Egg count

### Notes
- Location: Zimbabwe
- Setting rural, primary school
- Endemicity: seasonal transmission
- Date: not reported
- Funding: Rockefeller Foundation (financial support)
- Authors’ conclusion: Doses of 20 to 40 mg praziquantel may be equally effective in *S. haematobium* infection

### Risk of bias

| Bias                                           | Authors' judgement | Support for judgement                                               |
|-----------------------------------------------|--------------------|---------------------------------------------------------------------|
| Random sequence generation (selection bias)   | Unclear risk       | Randomly assigned.                                                   |
| Allocation concealment (selection bias)       | Unclear risk       | Not mentioned.                                                      |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk | Single blind manner "only the principal investigator knew which children had been assigned to which treatment group." |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk | Not mentioned.                                                      |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk | Loss to follow-up unclear, as only means and percentages of cure are reported. |
Taylor 1988 ZWE (Continued)

| Selective reporting (reporting bias) | Low risk | No evidence of selective reporting. |
|--------------------------------------|----------|-------------------------------------|
| Other bias                           | Low risk | No evidence for other source of bias. |

Tchuent 2004 CMR

| Methods | RCT |
|---------|-----|
|         | Diagnostics: collection of two urine samples on two consecutive days in 50 mL plastic screw cap vials, processing in field laboratory, agitation of urine (from dispersal of eggs) filtration of 10 mL (Nucleopore filter), egg counts |
|         | Length of follow-up 3, 6 and 9 weeks |
| Participants | School children, age not reported |
| Number of participants randomized: 592 |
| Inclusion: S. haematobium positive |
| Exclusion: not reported |
| Interventions | 1. Praziquantel 40 mg/kg single dose |
|                | 2. Praziquantel 40 mg/kg two single doses, dose interval three weeks |
|                | 3. Praziquantel 40 mg/kg three single doses, dose interval three weeks |
| Outcomes | Cure rates |
|          | Egg counts, egg reduction rates |
|          | Proteinuria |
| Notes | Location: Cameroon, Loum |
| Setting: urban, schools |
| Date: April to June 2002 |
| Endemicity: endemic all year, prevalence amongst school children 41.8%, trial carried out during high transmission period |
| Funding: European Commission INCO-DC (ICA-4-CT-2001-10079) |
| Authors' conclusion: No significant differences between the three dosing regimens, persistent high cure rates with a single dose of Praziquantel. Findings suggest efficacy of praziquantel against immature schistosoma stages. |

Risk of bias

| Bias                                 | Authors' judgement | Support for judgement |
|--------------------------------------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk | Assigned to random groups. |
| Allocation concealment (selection bias) | Unclear risk | Not mentioned. |
### Tchuente 2004 CMR (Continued)

| Risk of bias | Unclear risk | No use of placebo mentioned. |
|-------------|--------------|-----------------------------|
| Blinding of participants and personnel (performance bias) | Unclear risk | Not mentioned. |
| All outcomes | High risk | High loss to follow-up of 13% at six weeks, very high loss to follow-up of 58.6% at nine weeks (change in schools schedules). |
| Blinding of outcome assessment (detection bias) | Low risk | No evidence of selective reporting. |
| All outcomes | Low risk | No evidence of other bias. |

### van den Biggelaar 02 GAB

| Methods | RCT |
|---------|-----|
| Diagnostics: collection of urine samples on three different days, filtration of 10 mL urine, nucleopore pore size 13 μm, staining with ninhydrin, eggs count |
| Follow-up at two and three years, length of follow-up three years |
| Participants | School children aged five to 14 years |
| Participants randomized: 135 |
| Inclusion: positive for *S. haematobium* eggs |
| Exclusion: not reported |
| Interventions | Praziquantel 40 mg/kg single dose |
| Praziquantel 40 mg/kg in repeated doses, dose interval three months, over two years |
| Outcomes | Cure rates, failure rates |
| Egg counts |
| Microhaematuria |
| Notes | Location: Gaboon, near Lambarene |
| Setting: rural, village schools |
| Endemicity: high |
| Funding: not reported |
| Dates: not reported |
| Authors’ conclusion: relate to immunologic outcomes also measured by this trial, but not of interest for this review |

### Risk of bias
van den Biggelaar 02 GAB (Continued)

| Bias                                          | Authors' judgement | Support for judgement                                                                 |
|-----------------------------------------------|--------------------|--------------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)   | Unclear risk       | Allocated randomly.                                                                       |
| Allocation concealment (selection bias)       | High risk          | "The allocation of children to the treatment group was open."                            |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk | Use of placebo (given every three months) not mentioned.                                   |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk | Not mentioned.                                                                            |
| Incomplete outcome data (attrition bias)      | High risk          | High loss to follow-up (not balanced, reasons not given):                                 |
|                                                |                    | at 24 months 8%, 23%, 44% in different treatment groups;                                   |
|                                                |                    | at 36 months 40%, 64%, 77%.                                                              |
| Selective reporting (reporting bias)          | Low risk           | No evidence of selective reporting.                                                       |
| Other bias                                    | Low risk           | No evidence of other bias.                                                                |

Wilkins 1987 GMB

Methods
RCT
Diagnostics:
Follow-up at two to three months

Participants
Residents aged two to 19 years, median age 9.5 years
Participants randomized: not reported

Interventions
1. Praziquantel 10 mg/kg
2. Praziquantel 20 mg/kg
3. Praziquantel 40 mg/kg
4. Metrifonate 10 mg/kg
5. Praziquantel 10 mg/kg and metrifonate 10 mg/kg

Outcomes
Egg counts
Side effects

Notes
Location: Gambia Upper River Division, Nyanamari
Setting: rural
Endemicity: seasonal, trial conducted during season of low transmission
Authors' conclusion: Mass treatment of intensely infected groups should be based on the standard dose of praziquantel, with metrifonate as second choice.

Note: only one of the two trials reported in this publication, the Nyanamari trial, fulfilled the inclusion criteria.

### Risk of bias

| Bias                                   | Authors' judgement | Support for judgement                                                                 |
|----------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias) | Low risk           | "Subjects...were stratified into four age groups and within each age stratum were ordered by intensity of egg counts. They were then placed sequentially into groups of five. Computer generated random sets of the numbers one to five were used to allocate on subject in each group of five to each of the five regimens used." |
| Allocation concealment (selection bias) | Unclear risk       | Not mentioned.                                                                        |
| Blinding of participants and personnel (performance bias) All outcomes | Unclear risk       | Placebo and blinding not mentioned.                                                   |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk       | Not mentioned.                                                                        |
| Incomplete outcome data (attrition bias) All outcomes | Unclear risk       | Loss to follow-up unclear, as cure rates are reported as percentages.                 |
| Selective reporting (reporting bias) | Low risk           | No evidence of selective reporting.                                                    |
| Other bias                              | Low risk           | Baseline characteristics not reported.                                                |

### Characteristics of excluded studies [ordered by study ID]

| Study         | Reason for exclusion                                                                 |
|---------------|---------------------------------------------------------------------------------------|
| Aryeetey 1999 | Study of health education and community participation.                                |
| Ayoya 2007    | No comparison group (treatment groups receive praziquantel with or without iron supplements and multivitamins). |
| Bausch 1995   | Not a RCT.                                                                            |
| Beasley 1999  | This study compares a combination of praziquantel and albendazole with placebo. This outcome is not of interest for this review. |
| Bejon 2008    | Study of gastrointestinal helminths, not urinary schistosomiasis.                     |
| Study               | Reason for exclusion                                                                 |
|--------------------|--------------------------------------------------------------------------------------|
| Bhargava 2003      | This study does not report baseline criteria for control group, as the control group was not screened at baseline. |
| Boulanger 2007     | No comparison group (both groups receive artemunate).                                |
| Burchard 1984      | This study compares praziquantel 2 x 30 mg/kg to oltipraz, which is obsolete. Details of this trial can be seen in earlier versions of this review. |
| Clarke 1969        | Not a RCT.                                                                           |
| Clarke 1973        | Not a RCT, allotted to groups, "for practical reasons, the infected children in the two senior grades were set aside for treatment with i.m. hycanthone". |
| Creasey 1986       | This study compares different doses of praziquantel (8 mg/kg, 15 mg/kg and 20 mg/kg) combined with oxamnique in patients with *S. haematobium* and *S. mansoni* co-infections. A comparison of the praziquantel dosages used is not of interest for this review. |
| Danso-Appiah 2009  | Systematic review.                                                                  |
| Davis 1966         | This study evaluates different doses of ambilhar which is now obsolete. Details of this trial can be seen in earlier versions of this review. |
| Davis 1979         | Outcomes are not reported per treatment group, only for the total number of participants randomized. |
| De Clercq 2002     | Not a RCT, "systematically allocated".                                               |
| Druilhe 1981       | Not a RCT.                                                                           |
| el Hawey 1990      | No comparison group.                                                                 |
| el Tayeb 1988      | This study compares praziquantel 2 x 20 mg/kg to oltipraz 2 x 15 mg/kg, which is now obsolete. Details of this trial can be seen in earlier versions of this review. |
| el-Zayadi 1985     | No outcome of interest reported.                                                    |
| Erikstrup 2008     | This is a study of HIV and *S. haematobium* or *S. mansoni* co-infection, no outcomes of interest for this review are reported. |
| Fontanilles 1964   | Conference speech.                                                                  |
| Forsyth 1964       | Not a RCT. "At three of the schools, every sixth injected child received "curative" treatment..." |
| Garba 2001         | Study of health education.                                                           |
| Garba 2004         | This study evaluates mass treatment with praziquantel without comparison group.     |
| Hammad 1997        | This cross-sectional study evaluates the diagnosis of urinary schistosomiasis by reagent strip and parasitological methods. |
| Jewsbury 1977      | No comparison group (sequence of treatment, then prophylaxis within one group).     |
| Jinabhai 2001      | This study compares a combination of praziquantel and albendazole with placebo. This outcome is not of interest for this review. |
| Study               | Reason for exclusion                                                                 |
|--------------------|---------------------------------------------------------------------------------------|
| Jordan 1966        | Quasi-RCT. “Children were allocated to Groups 1-4 corresponding to different regimens of treatment, in rotation down the list (pre-treatment results in descending order), thus ensuring four groups matched for egg output.” |
| Kardaman 1983      | No comparison group.                                                                   |
| Kern 1984          | Study of intestinal manifestations of schistosomiasis, very low number for *S. haematobium* positive patients, outcome data not reported separately. |
| King 1989          | Review article.                                                                        |
| King 1992          | Data reported in other publications.                                                   |
| Kurz 1986          | This study evaluates metrifonate in hookworm infections.                               |
| Latham 1983        | No comparison group.                                                                   |
| Lucas 1969         | This study reports ultrasound findings in patients with urinary schistosomiasis after treatment with niridazole to an untreated control. Niridazole is now obsolete. |
| Mwanakasale 2009   | Study of iron supplementation in *S. haematobium* treatment with no outcomes of interest for this review. |
| N’Goran 2003       | Study of *S. haematobium* prevention.                                                  |
| Nagaty 1962        | This trial studies the therapy of drug side effects in urinary schistosomiasis treatment. |
| Odongo-Aginya 1996 | Not a RCT, study of *S. mansoni*.                                                      |
| Olsen 2007         | Review article.                                                                        |
| Pitchford 1978     | No comparison group.                                                                   |
| Podgore 1994       | Study of *S. haematobium* prevention.                                                  |
| Rabarijaona 2001   | Epidemiological survey.                                                                |
| Rey 1984           | This study compares oltipraz 30 mg/kg to a combination of metrifonate 10 mg/kg and niridazole 25 mg/kg. Niridazole and oltipraz are now obsolete. |
| Rugemalila 1984    | Study of *S. mansoni*.                                                                 |
| Schutte 1983       | No comparison group.                                                                   |
| Sellin 1986        | This study compares metrifonate 10 mg/kg to oltipraz 30 mg/kg, which is now obsolete. |
| Sissoko 2009 MLI   | This study compared praziquantel to a combination of artesunate with sulfamethoxypyrazine pyrimethamine; it is therefore not possible to attribute observed effects to artesunate alone. |
| Snyman 1997        | Study of calcitriol as experimental antischistosomal treatment.                        |

| van Lieshout 1994   | Study of S. mansoni.                                                                  |
| Wilkins 1987 Simoto trial | Not a RCT, alternate allocation.                                                     |
| Wolfe 1967          | Not a RCT.                                                                            |
| Xiao 2002           | Review article.                                                                       |
| Zwingenberger 1990  | Case study.                                                                           |

### DATA AND ANALYSES

#### Comparison 1. Praziquantel 40 mg/kg single dose versus placebo

| Outcome or subgroup title | No. of studies | No. of participants | Statistical method | Effect size     |
|---------------------------|----------------|---------------------|--------------------|-----------------|
| 1 Parasitological failure | 8              |                     | Risk Ratio (M-H, Random, 95% CI) | Subtotals only  |
| 1.1 at one month to two months | 7              | 864                 | Risk Ratio (M-H, Random, 95% CI) | 0.42 [0.29, 0.59] |
| 1.2 at three months       | 3              | 354                 | Risk Ratio (M-H, Random, 95% CI) | 0.51 [0.34, 0.77] |
| 1.3 at five months        | 1              | 54                  | Risk Ratio (M-H, Random, 95% CI) | 0.73 [0.58, 0.91] |
| 1.4 at six months         | 3              | 332                 | Risk Ratio (M-H, Random, 95% CI) | 0.42 [0.10, 1.84] |
| 1.5 at eight months       | 1              | 209                 | Risk Ratio (M-H, Random, 95% CI) | 0.14 [0.08, 0.22] |
| 2 Haematuria at eight weeks | 1             | 119                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.53 [0.33, 0.84] |
| 3 Haemoglobin             | 2              |                     | Mean Difference (IV, Random, 95% CI) | Subtotals only  |
| Outcome or subgroup title | No. of studies | No. of participants | Statistical method | Effect size |
|---------------------------|---------------|---------------------|--------------------|-------------|
| 3.1 at baseline           | 2             | 727                 | Mean Difference (IV, Random, 95% CI) | -0.17 [-0.35, 0.02] |
| 3.2 at six to eight months | 2             | 727                 | Mean Difference (IV, Random, 95% CI) | -0.08 [-0.24, 0.09] |
| 4 Adverse events          | 2             |                     | Risk Ratio (M-H, Fixed, 95% CI) | Subtotals only |
| 4.1 Diarrhoea             | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.0 [0.0, 0.0] |
| 4.2 Vomiting              | 2             | 226                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.67 [0.15, 2.87] |
| 4.3 Dizziness             | 2             | 226                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.37 [0.11, 1.27] |
| 4.4 Anorexia              | 1             | 70                  | Risk Ratio (M-H, Fixed, 95% CI) | 0.20 [0.05, 0.85] |
| 4.5 Abdominal pain        | 2             | 226                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.50 [0.22, 1.14] |
| 4.6 Tiredness             | 1             | 70                  | Risk Ratio (M-H, Fixed, 95% CI) | 0.48 [0.14, 1.71] |
| 4.7 Weakness              | 1             | 70                  | Risk Ratio (M-H, Fixed, 95% CI) | 0.96 [0.36, 2.57] |
| 4.8 Headache              | 2             | 226                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.19 [0.02, 1.47] |
| 4.9 Fever                 | 2             | 226                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.12 [0.07, 17.22] |
| 4.10 Pain in limbs        | 1             | 70                  | Risk Ratio (M-H, Fixed, 95% CI) | 5.59 [0.28, 112.34] |
| 4.11 Itching              | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.0 [0.19, 5.28] |
| 4.12 Cough                | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.0 [0.09, 10.78] |
| 4.13 Chills               | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.5 [0.16, 14.07] |
| 4.14 Nausea               | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.0 [0.09, 10.78] |
| 4.15 Constipation         | 1             | 156                 | Risk Ratio (M-H, Fixed, 95% CI) | 1.51 [0.06, 36.54] |

### Analysis 1.1. Comparison 1 Praziquantel 40 mg/kg single dose versus placebo, Outcome 1 Parasitological failure.

| Study or subgroup | PZQ 40mg/kg n/N | Placebo n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-------------|--------------------------------|--------|--------------------------------|

Total events: 4 (PZQ 40mg/kg), 7 (Lower doses)
Heterogeneity: Tau²=0.79; Chi²=1.52, df=1(P=0.22); I²=34.26%
Test for overall effect: Z=0.34(P=0.73)

#### 2.10.4 Abdominal pain

| Study or subgroup | PZQ 40mg/kg n/N | Lower doses n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-----------------|--------------------------------|--------|--------------------------------|
| Davis 1981 ZMB    | 9/45            | 4/53            | 47.64%                         | 2.65[0.87,8.03] |
| McMahon 1979 TZA | 6/33            | 11/32           | 52.36%                         | 0.53[0.22,1.26] |
| **Subtotal (95% CI)** | **78**          | **85**          |                                | **100%** | **1.14[0.23,5.56]** |

Total events: 15 (PZQ 40mg/kg), 15 (Lower doses)
Heterogeneity: Tau²=1.05; Chi²=5.08, df=1(P=0.02); I²=80.32%
Test for overall effect: Z=1.16(P=0.87)

#### 2.10.5 Tiredness

| Study or subgroup | PZQ 40mg/kg n/N | Lower doses n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-----------------|--------------------------------|--------|--------------------------------|
| McMahon 1979 TZA | 3/33            | 9/32            | 61.42%                         | 0.32[0.1,1.09] |
| **Subtotal (95% CI)** | **33**          | **32**          |                                | **100%** | **0.32[0.1,1.09]** |

Total events: 3 (PZQ 40mg/kg), 9 (Lower doses)
Heterogeneity: Not applicable
Test for overall effect: Z=1.163(P=0.07)

#### 2.10.6 Weakness

| Study or subgroup | PZQ 40mg/kg n/N | Lower doses n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-----------------|--------------------------------|--------|--------------------------------|
| McMahon 1979 TZA | 6/33            | 5/32            | 38.58%                         | 0.16[0.02,1.27] |
| **Subtotal (95% CI)** | **33**          | **32**          |                                | **100%** | **1.16[0.39,3.44]** |

Total events: 6 (PZQ 40mg/kg), 5 (Lower doses)
Heterogeneity: Not applicable
Test for overall effect: Z=0.27(P=0.78)

#### 2.10.7 Headache

| Study or subgroup | PZQ 40mg/kg n/N | Lower doses n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-----------------|--------------------------------|--------|--------------------------------|
| Davis 1981 ZMB    | 5/45            | 6/53            | 61.42%                         | 0.98[0.32,3] |
| McMahon 1979 TZA | 1/33            | 6/32            | 38.58%                         | 0.16[0.02,1.27] |
| **Subtotal (95% CI)** | **78**          | **85**          |                                | **100%** | **0.49[0.08,2.85]** |

Total events: 12 (PZQ 40mg/kg), 12 (Lower doses)
Heterogeneity: Tau²=0.99; Chi²=2.39, df=1(P=0.12); I²=58.07%
Test for overall effect: Z=0.79(P=0.43)

#### 2.10.8 Fever

| Study or subgroup | PZQ 40mg/kg n/N | Lower doses n/N | Risk Ratio M-H, Random, 95% CI | Weight | Risk Ratio M-H, Random, 95% CI |
|-------------------|-----------------|-----------------|--------------------------------|--------|--------------------------------|
| McMahon 1979 TZA | 1/33            | 0/32            | 100%                           | 2.91[0.12,68.95] |
| **Subtotal (95% CI)** | **33**          | **32**          |                                | **100%** | **2.91[0.12,68.95]** |

Total events: 0 (PZQ 40mg/kg), 0 (Lower doses)
Heterogeneity: Not applicable
Test for overall effect: Z=0.66(P=0.51)

#### 2.10.9 Pain in limbs

| Group | Favours PZQ 40mg/kg | Lower doses | p-value |
|-------|---------------------|-------------|---------|
|       | 0.001               | 0.1         | 0.10    |
|       | 1                   | 0.05        | 0.30    |
|       | 10                  | 0.01        | 0.20    |
|       | 1000                | 0.001       | 0.40    |

favours PZQ 40mg/kg
Comparison 3. Praziquantel 40 mg/kg single dose versus 2 x 20 mg/kg split dose

| Outcome or subgroup title | No. of studies | No. of participants | Statistical method | Effect size |
|---------------------------|----------------|---------------------|-------------------|-------------|
| 1 Parasitological failure | 4              |                     | Risk Ratio (M-H, Fixed, 95% CI) | Subtotals only |
| 1.1 at one month          | 3              | 374                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.75 [0.51, 1.11] |
| 1.2 at three months       | 3              | 361                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.74 [0.45, 1.20] |
| 1.3 at six to seven months| 3              | 234                 | Risk Ratio (M-H, Fixed, 95% CI) | 0.83 [0.51, 1.35] |
| 2 Adverse events          | 3              |                     | Risk Ratio (M-H, Fixed, 95% CI) | Subtotals only |

Drugs for treating urinary schistosomiasis (Review)
## ADDITIONAL TABLES

### Table 1. Population based treatment according to prevalence among schoolchildren (WHO)

| Category            | Prevalence among school-aged children                                                                 | Action to be taken                                                                 | Comment                                                                 |
|---------------------|--------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------|
| High-risk community | 50% by parasitological methods (intestinal or urinary schistosomiasis); or 30% by questionnaire for visible haematuria (urinary schistosomiasis) | Treat all school-age children (enrolled and not enrolled) once a year              | Also treat adults considered to be at risk (from special groups to entire communities living in endemic areas) |
| Moderate-risk community | > 10 to < 50% by parasitological methods (intestinal and urinary schistosomiasis); or 30% by questionnaire for visible haematuria (urinary schistosomiasis) | Treat all school-age children (enrolled or not enrolled) once every two years      | Also treat adults considered to be at risk (special groups only)       |
| Low-risk community  | < 10% by parasitological methods (intestinal and urinary schistosomiasis)                             | Treat all school-age children (enrolled and not enrolled) twice during their primary schooling age (for example, once on of suspected cases entry and once on exit) | Praziquantel should be available in dispensaries and clinics for treatment of suspected cases. |

### Table 2. Definition of cure, reporting and calculation of egg counts

| Study ID          | Definition cure                                                                 | Reporting of egg counts/10 mL urine | Methods to calculate egg counts | Comment                                                                 |
|-------------------|--------------------------------------------------------------------------------|------------------------------------|-------------------------------|------------------------------------------------------------------------|
| Abden Abdi 1989 SOM | Patients without schistosome eggs in their urine after treatment              | Mean (SD), % ER                    | Not reported                  | No hatching test employed, cured might be underestimated because of dead eggs |
| Al Aska 1990 SAU  | Clinical improvement Disappearance of ova from the urine on three successive examinations | Mean, range                        | Not reported                  | —                                                                      |
| Basra 2012 GAB    | Three consecutive urine samples without presence of eggs                        | Median, interquartile range         | Not reported                  | —                                                                      |
| Befidi Mengue 1992 CMR | Cure not reported                                                               | GMEC                               | Not reported                  | Hb and weight as outcomes                                              |
Table 2. Definition of cure, reporting and calculation of egg counts (Continued)

| Study Year | Test | Definition of cure | Calculation of egg counts | Additional Information |
|------------|------|-------------------|---------------------------|------------------------|
| Borrmann 2001 GAB | Two negative egg counts on two consecutive days | GMEC | Arithmetical mean of two egg counts per participant before and after treatment including 0 egg counts (cured patients). Geometric means of these arithmetic means. | We received the data file from the study author. Day to day variation in egg counts explains 10% cure rate with placebo. |
| Davis 1981 ZMB | Defined as three negative urine defined as the absence of hatched miracidia, although recently dead or black eggs might be present. | Geometric mean miracidial count | At follow-up: If the first urine specimen contained hatched miracidia, then random 10 mL samples were taken from further bladder collections, the miracidial count was recorded, and the geometric mean of the counts was compared directly with the geometric mean of the pre-treatment counts. | Quantitative hatching test. |
| de Jonge 1990 SDN | No definition of cure given, presumably absence of urinary egg excretion | Minimum and maximum value, median, 90% value | Not reported | Excretion of eggs following treatment |
| Inyang Etoh 2009 NGA | No definition of cure given, cure rates and egg reduction rates as end points | Mean ± SD | "Treatment-related changes in egg counts were investigated using paired Student's t test." | — |
| Jewsbury 1976 ZWE | No definition of cure given | "median urine egg count" | Not reported | — |
| Kardaman 1985 SDN | No definition of cure given, "negative" | GMEC | Not reported | "It would appear that the cure rate determined in any trial is dependent on the pretreatment egg count and on the ... urine examination techniques used." |
| Keiser 2010 CIV | Absence of urinary egg excretion Cure rate (CR, defined as the percentage of children excreting no S. haematobium eggs 26 days after treatment among children with confirmed parasites at baseline) | GMEC | S. haematobium egg counts before and after treatment were averaged for every child (arithmetical mean) and the GM egg count for each treatment group was calculated. Because egg counts are over dispersed, they were logarithmically transformed log [count+1], and the GM was expressed as the antilogarithm of the mean. Egg reduction rate (ERR) defined as reduction of geometric mean (GM) egg count among S. haematobium positive children after treatment, compared with the respective GM pretreatment. | (ERR; defined as reduction of geometric mean egg count among S. haematobium–positive children after treatment, compared with the respective geometric mean pre-treatment) |
### Table 2. Definition of cure, reporting and calculation of egg counts (Continued)

The ERR was calculated as (1 - [GM egg count after treatment/GM egg counts at enrolment]) x 100

| Study          | Definition of cure | Reporting | Calculation of Egg Counts | Notes                                                                 |
|---------------|--------------------|-----------|---------------------------|----------------------------------------------------------------------|

| King 1990 KEN | No definition given | AMEC      | GMEC Not reported         | Infection was identified and quantified by Nucleopore filtration     |
| King 2002 KEN | Cure defined as egg-negative | GMEC | Not reported             | —                                                                      |
| McMahon 1979 TZA | Probable cure rate: excretion of no or only non-viable eggs in the urine | GMEC, 95% confidence limit of the mean | Not reported             | —                                                                      |
| McMahon 1983 TZA | People were considered cured when no eggs or non-viable eggs were excreted in the urine | Screening: GMEC of miracidia/10 mL urine reduction in egg excretion | "In non cured cases the reduction of egg excretion was calculated." | —                                                                      |
| Mott 1985 GHA | Absence of *S. haematobium* eggs in two random 5 mL samples of urine from the same specimen | GMEC 5 mL urine samples reduction in GMEC | Not reported | —                                                                      |
| Olds 1999 KEN | No definition given | GMEC      | "Egg counts are geometric means in subjects who remained infected. Reduction in egg no. after treatment in infected children was significant in all infections at 45 days." | —                                                                      |
| Omer 1981 SDN | 100% reduction of egg excretion (absence of egg excretion in the urine) or 98% egg reduction and neg miracidial hatching test | GMEC | Not reported | Only children with GMEC > 60/10 mL (in three egg counts) included |
| Oyediran 1981 NGA | No definition of cure given | GMEC mean ± SD | Not reported | Only children with GMEC > 60/10 mL (in three egg counts) included |
| Pugh 1983 MWI | No definition of cure given | AMEC | % egg count reduction | We did not use a hatching test to determine the viability of excreted ova since percentage reduction in egg output was determined by comparing the arithmetic and geometric means of pooled egg counts before and after treatment. The geometric mean was obtained by recording the log. |
**Table 2. Definition of cure, reporting and calculation of egg counts**

| Study          | Definition of cure given | Reporting | Calculation of egg counts |
|----------------|--------------------------|-----------|---------------------------|
| Rey 1983 NER   | No definition given      | AMEC      | Not reported              |
|                | "nombre moyenue" (average number) |           |                           |
| Rey 1984 NER   | No definition given, "negativation" | AMEC      | Not reported              |
|                | moyenne des nombres d’oeufs/10 mL urine (Number average) |           |                           |
| Sacko 2009 MLI| The cure rate was calculated as the proportion of infected individuals who became parasitologically negative (0 egg/10 mL urine based on three urine samples) at three months post treatment | GMEC      | Individual egg counts were calculated as the mean number of eggs per 10 mL of urine in the three urine samples. To compare the effect of the treatment on the intensity of the infection at 3, 6 and 18 months geometric mean egg/10 mL for all urine samples examined for *S. haematobium* eggs were calculated as $\log_{10}(x+1)$ to allow egg count of 0 to be included in the analysis. |
| Stephenson 1985 KEN | no definition of cure given | AMEC      | Not reported              |
| Stephenson 1989 KEN | —                          | AMEC      | Not reported              |
| Taylor 1988 ZWE| Cure defined as negative egg counts | GMEC      | Not reported              |
|                | "Infections as were cured by a negative GMEC at 1,3 and 6 months" |           |                           |
| Tchuente 2004 CMR | The parasitologic cure rates were calculated as the proportion of children excreting eggs at the first survey before treatment and who were not excreting eggs in their urine after treatment. | GMEC      | Geometric mean (GM) values of all individuals were used to assess average egg counts of each group. The GM was calculated as the antilogarithm of the mean of all log transformed egg counts + 1. The intensity reduction rate was calculated as $[1 - \frac{\text{GM egg counts per 10 mL of urine after treatment (GM egg counts per 10 mL before treatment)}}{\times 100}]$ |
|                |                           |           |                           |

---

**Note:** GMEC = Geometric Mean Egg Count; AMEC = Arithmetic Mean Egg Count; SE = Standard Error; N = Number of participants.
1Baseline data not reported separately per group.
2A reduction as low as 46% after praziquantel 40 mg/kg was not observed by any other study that reported this outcome. At six months, five other studies reported % egg reduction above 90% (see Table 4 and Table 5)
3Heavy and light infections together; N = 77 for Praziquantel 40 mg/kg and N = 72 for Praziquantel 30 mg/kg.
4GMEC/10 mL urine, stratum 1: 60 to 250, stratum 2: 251 to 500, stratum 3 > 500.

1 Stratum I: light infections < 50 eggs/10 mL, praziquantel (N = 77), placebo (N = 90). "Pretreatment light infections exhibited better cure rates for *S. haematobium* than pretreatment heavy infections". Praziquantel (N = 77), placebo (N = 90).

2 Baseline imbalance in terms of intensity of infection "In accordance with local ethical guidelines the placebo group consisted only of children with light (20 to 124 ova/10 mL or moderate (125 to 4999 ova/10 mL) infections before treatment."

Praziquantel 40 mg/kg single dose x 2, interval three weeks: one arm received praziquantel single at baseline, one arm received a second dose at three weeks, one arm received the second dose at three weeks and a third dose at six weeks. Follow-up for all groups at six weeks and nine weeks.

Strata: light infection < 50/10 mL, heavy infection > 50/10 mL.

Reports that anthropometric data were measured at baseline and day 45, no significant difference was found before and after treatment with albendazole and praziquantel. Data not shown in the publication.
1 Stephenson 1989 KEN reports growth greater than placebo. Sixteen participants per group are followed up at 5 weeks. Appetite measured by mL of porridge intake. No significant difference between metrifonate and praziquantel groups for the outcomes resting heart rate, Harvard step test and appetite.

2 Befidi Mengue 1992 CMR has 238 participants in the praziquantel group and 198 in the placebo group. “MUAC was the only anthropometric measure with a significant difference between Praziquantel and Placebo group.” No significant differences (before and after interventions) between the groups for height, weight, TSS; TSS: triceps skinfold thickness, MUAC: middle upper arm circumference.

3 Stephenson 1989 KEN At follow up at eight months, there are 105 participants in the praziquantel group and 104 in the placebo group.
### Praziquantel 40 mg/kg or metrifonate 10 mg/kg single dose versus placebo: growth outcomes

| Trial ID       | Time point | Measure                      | Praziquantel 40 mg/kg or Metrifonate 10 mg/kg single dose | Placebo | P value for difference between treatment and placebo group |

Stephenson 1989 KEN at 5 weeks, there were 16 participants in the praziquantel group and 16 in the metrifonate group. At 8 months, there were 105 participants in the praziquantel group and 103 in the metrifonate group.

Appendix 5. Appendix: Additional tables for adverse events

Praziquantel 40 mg/kg single dose versus placebo: adverse events

| Trial ID       | N (praziquantel treatment arm) | Adverse event monitoring                                                                 | Blinding                                           | Summary of adverse events findings                                                                 |
|---------------|--------------------------------|-----------------------------------------------------------------------------------------|---------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Pugh 1983 MWI | N = 97 (Praziquantel 40 mg/kg) | No comment                                                                              | Blinded for participants and clinicians           | "Treatment was well tolerated".                                                                   |
| Borrmann 2001 GAB | N = 300                      | Adverse events recorded on day 1, 3 and 7 (changes in the participants condition, compared with baseline) | Blinded for participants and clinicians           | No difference between treatment groups regarding the number of adverse events, or distribution of particular adverse events.  
All treatment regimens well tolerated.  
Six moderate and 127 mild adverse events reported.  
Most common adverse events: abdominal pain (overall 14%) and headache (12%).                                           |
| Inyang Etoh 2009 NGA | N = 312                   | Careful monitoring for adverse events by trial physician, any potential adverse events were noted and monitored for up to 72 hours post treatment. Final assessment on day 56 for 2 consecutive days. | Unclear                                           | No difference between treatment groups.  
No severe adverse events reported within one hour of medication, no child required immediate medical care.  
Good tolerance of all treatment regimens.  
97 incidences of adverse events reported.  
33 cases of headache.                                           |
| McMahon 1979 TZA | N = 101                     | All children examined clinically before and four and 24 hours after treatment. Symptoms recorded after both general and specific queries (anorexia, nausea, vomiting, abdominal pain, diarrhoea, giddiness, tiredness, weakness, body pain, headache and fever) | Unclear                                           | No difference between treatment groups and placebo group, no side effects related to the drug or to infection intensity  
common side effects equally frequent before and after treatment                                           |
(Continued)

Olds 1999 KEN

N = 193
98 (Praziquantel and albendazole)
95 (Praziquantel)

Surveillance for 48 hours for specific side effects (drug-related side effect compared with parasite egg counts, symptoms over the past two weeks, physical examination and treatment group).

Participants asked for overall rating of side effects and limitations of activity recording of request for medication for symptoms and hospitalisation.

Blinded for clinicians, participants not blinded for outcome assessors

Data not reported for S. haematobium separately.

Vomiting, abdominal pain, headache, interference with normal activity, diarrhoea, bloody diarrhoea, request for additional medication for symptoms, and total side effects were all higher in children with documented schistosomiasis.

Taylor 1988 ZWE

N = 283
77 (Praziquantel 40 mg/kg)
72 (Praziquantel 30 mg/kg)
61 (Praziquantel 20 mg/kg)
73 (Praziquantel 10 mg/kg)

No comment

Blinded for clinicians, participants not blinded for outcome assessors

"Side effects were not monitored but it appeared that those receiving smaller doses received less abdominal discomfort."

Footnotes

Befidi Mengue 1992 CMRand Stephenson 1989 KEN did not comment on adverse events.

Praziquantel 40 mg/kg single dose versus 30 mg/kg single dose: adverse events

### Summary of adverse events

| McMahon 1979 TZA | Omer 1981 SDN | Oyediran 1981 NGA | Taylor 1988 ZWE |
|------------------|--------------|-------------------|------------------|
| All children examined clinically before and four and 24 hours after treatment. Symptoms recorded after both general and specific queries. Active surveillance, likely to be prospective. | Side effects recorded before and after treatment. Method of monitoring not described. Monitoring of vital signs (pulse rate, respiratory rate, blood pressure) at 24 and 48 hours. | Clinical examination pre-treatment and 18 to 24 hours post treatment to detect any unwanted side effects of praziquantel (pulse rate, systolic and diastolic blood pressure). Haematological and biochemical blood tests before (standard blood count, Hb electrophoresis, Bilirubin, SGPT, SGOT) and 18 to 24 hours after treatment (packed cell volume, total and differential white blood count, Bilirubin, SGOT, SGPT). Therapeutic doses of chloroquine (for Malaria) and levotetramisole (ascariasis) given to all subjects. | No comment |
| Unclear | Unclear | Unclear | Blinded for clinicians, participants. Not blinded for outcome assessors. |
| No difference between groups. Common side effects equally frequent before and after treatment and in treated and placebo groups. No side effects related to the drug or to infection intensity. | Difference between groups not reported. Mild diarrhoea on day one following treatment in 31% of patients. All other symptoms mild and transient. | Difference in clinically diagnosed side effects not reported. No difference between groups in post treatment haematological and biochemical findings (within normal limits). Very good tolerance of praziquantel, very few side effects (two cases of moderate abdominal pain). | "Side effects were not monitored but it appeared that those receiving smaller doses received less abdominal discomfort." |

### Footnotes

King 2002 KEN, Mott 1985 GHA, King 2002 KEN and Wilkins 1987 GMB did not report adverse events.

1 Taylor 1988 ZWE also reported a treatment arm of 61 participants who received Praziquantel 20 mg/kg and a treatment arm of 73 participants who received Praziquantel 10 mg/kg.

No difference between groups in post treatment haematological and biochemical findings (within normal limits). Very good tolerance of praziquantel, very few side effects (two cases of moderate abdominal pain). |
| Taylor 1988 ZWE | 283 | No comment | Blinded for clinicians, participants. Not blinded for outcome assessors. | "Side effects were not monitored but it appeared that those receiving smaller doses received less abdominal discomfort." |

### Praziquantel versus artemesunate: adverse events

| Trial ID | N (treatment arms) | Adverse event monitoring | Blinding of participants and staff | Summary of adverse events findings |
|----------|--------------------|--------------------------|-----------------------------------|-----------------------------------|
| Keiser 2010 CIV | N = 83 | Observation for AE for 3 hours after the first dose AE monitoring until 96 hours after the first dosing. Interview with standardized questionnaire at 24, 48, 72 and 96 hours. Clinical examination in case AE occurred. Classification of AE as mild, moderate, severe or life threatening. | Not blinded | No difference between the four treatment groups (headache, coughing, vomiting, vertigo or chills). Abdominal pain more frequent in the mefloquine group (98%, \( P < 0.001 \)), mefloquine-artesunate (83%, \( P = 0.008 \)), artesunate (60%, \( P = 0.37 \)) than in the praziquantel group (46%). More participants had at least one AE in any of the assessments in the mefloquine group (100%), in the mefloquine-artesunate group (94%) and in the artesunate group (80%) than in the praziquantel group (61%). No serious or life-threatening adverse events, no hospital admissions due to AE. no neuropsychological AE, no trial discontinuation due to AE. |
| Borrmann 2001 GAB | N = 300 | Adverse events recorded on day 1, 3 and 7 (changes in the participants condition, compared with baseline). Prospective surveillance. | Blinded for participants and clinicians | All treatment regimens well tolerated. Six moderate and 127 mild adverse events were reported. No difference between treatment groups regarding the number of adverse events, or distribution of particular adverse events, most common adverse events: abdominal pain (overall 14%) and headache (12%). |
Inyang Etoh 2009 NGA

N = 312
104 (praziquantel; 52 with placebo, 52 without placebo)
104 (artesunate 4 mg/kg for 3 days; 52 with placebo, 52 without placebo).
52 (praziquantel 40 mg/kg and artemesunate 4 mg/kg for 3 days)
52 (placebo)

Careful monitoring for adverse events by trial physician, any potential adverse events were noted and monitored for up to 72 hours post treatment.
Final assessment on day 56 for two consecutive days.
Unclear if active or passive surveillance

Unclear

No difference between treatment groups
No severe adverse events reported within one hour of medication, no child required immediate medical care.
97 incidences of adverse events reported
33 cases of headache
Good tolerance of all treatment regimens

Praziquantel versus mefloquine: adverse events

|               |              |                            |          |                                    |

Praziquantel versus Praziquantel and ALB: adverse events

| Trial ID          | Participants | Adverse events monitoring | Blinding | Summary of adverse events findings |
|-------------------|--------------|----------------------------|----------|-----------------------------------|
|                   |              |                            |          |                                    |
Olds 1999 KEN

N = 193
98 (Praziquantel and albendazole)
95 (Praziquantel)

AE monitoring for 48 hours for predefined AE
Double blind

65% of side effects for *S. haematobium* reported within four to six hours. Symptoms usually resolved within two hours with or without relief medication.

Data not reported for *S. haematobium* separately.

Appendix 6. Appendix: Ultrasound findings

Praziquantel 40 mg/kg single dose versus 20 mg/kg single dose: ultrasound findings

| Trial ID   | Time point | Measure                                      | Praziquantel 40 mg/kg (SD) | Praziquantel 20 mg/kg (SD) |
|------------|------------|----------------------------------------------|-----------------------------|-----------------------------|
|            |            | Baseline | Follow-up | Baseline | Follow-up |
| King 2002 KEN 1 | 9 months | Number of participants with haematuria/total | 22/32 (69%) | 16/32 (50%) | 20/32 (62%) | 17/32 (53%) |
|            |            | N = 264 for both groups                       |                            |                             |              |              |
|            |            | Mild hydronephrosis (%)                       | 25% | 15% | 21% | 18% |
|            |            | Moderate hydronephrosis (%)                   | 5% | 4% | 11% | 0% |
|            |            | Severe hydronephrosis (%)                     | 5% | 2% | 3% | 2% |
|            |            | Mild bladder abnormalities (%)                | 11% | 4% | 17% | 6% |
|            |            | Severe bladder abnormalities (%)              | 8% | 0% | 6% | 0% |

1Haematuria measured by urine dipstick, "no statistical difference", "study might be underpowered, for ultrasound findings" all severe bladder abnormalities were eliminated.

Praziquantel 40 mg/kg 1x/year versus metrifonate 10 mg/kg 3x/year: ultrasound findings

| Trial ID   | Time point | Measure                                      | Praziquantel 40 mg/kg | Meftrifonate 10 mg/kg |
|------------|------------|----------------------------------------------|------------------------|-----------------------|
|            |            | Baseline | Follow-up | 1x/year | 3x/year |
| King 1990 KEN | 12 months | Bladder wall thickness | 35% improvement | 29% improvement |
|            |            | 8% deterioration | | 9% deterioration |
|            |            | Bladder deformity (granulomata) | 21% improvement | 15% improvement |
|            |            | 6% deterioration | | 2% deterioration |

CONTRIBUTIONS OF AUTHORS

VK developed the protocol with input from PG and DS. VK and FZ assessed eligibility and extracted the data. We resolved any disagreements through discussion with DS and PG. VK entered the data and drafted the manuscript with input from DS, PG and PO. DS, PG and PO assisted in interpretation of the results and revisions of the text.

DECLARATIONS OF INTEREST

We have no known conflicts of interest.

SOURCES OF SUPPORT

Internal sources

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

While inclusion criteria of the first protocol included all RCTs which studied antischistosomal drugs, we decided to change the protocol. We excluded trials which evaluated obsolete drugs as ambilhar, oltipraz and niridazole. We also excluded studies which compared a combination of praziquantel and albendazole to placebo only, as this comparison is not of interest for this review. We included trials evaluating metronidazole.

We did not contact researchers or organizations looking for unpublished studies, as stated in the protocol. We did not report parasitological outcomes at three months as primary outcomes.

The older version of this review concluded that both metrifonate and praziquantel were effective in treating urinary schistosomiasis, even if metrifonate had operational disadvantages. As implications for further research, evaluation of different metrifonate doses and regimens and of evaluation of artemisinin drugs and of combination therapy is recommended.

While we agree with these conclusions, the data on egg reduction allow some further recommendations. We have newly included three trials evaluating artemisinin drugs, and one recent trial using mefloquine, and present this new evidence here.

Additional analysis carried out in this edition of the review, which was not in the previous edition (Danso-Appiah 2008), is the presentation of egg reduction rates in summary tables.
