Abstract: The Mediterranean diet is known to be one of the healthiest dietary patterns in the world due to its relation with a low morbidity and mortality for some chronic diseases. The purpose of this study was to review literature regarding the relationship between Mediterranean diet and healthy aging. A MEDLINE search was conducted looking for literature regarding the relationship between Mediterranean diet and cardiovascular disease (or risk factors for cardiovascular disease), cancer, mental health and longevity and quality of life in the elderly population (65 years or older). A selection of 36 articles met the criteria of selection. Twenty of the studies were about Mediterranean diets and cardiovascular disease, 2 about Mediterranean diets and cancer, 3 about Mediterranean diets and mental health and 11 about longevity (overall survival) or mental health. The results showed that Mediterranean diets had benefits on risks factors for cardiovascular disease such as lipoprotein levels, endothelium vasodilatation, insulin resistance, the prevalence of the metabolic syndrome, antioxidant capacity, the incidence of acute myocardial infarction, and cardiovascular mortality. Some positive associations with quality of life and inverse associations with the risk of certain cancers and with overall mortality were also reported.

Keywords: Mediterranean diet, elderly, health, review

Introduction

According to the 2002 World Health Organization (WHO) health report, a diet poor in fruits and vegetable is the third preventable risk factor for chronic diseases (specific types of cancers, cerebrovascular diseases and ischemia) which have replaced infectious disease as the leading cause of morbidity and mortality in the world. The same report showed that among the twenty countries with the highest life expectancy in the world, four of them are Mediterranean countries (France, Italy, Spain, and Greece) (WHO 2001).

Mediterranean countries share a common dietary pattern first defined by Ancel Keys (Keys et al 1986) when he observed important geographical differences in the incidence rates of cardiovascular disease, certain cancers and other nutrition-related diseases that were mostly attributable to supposedly unhealthy food patterns whereas the Mediterranean dietary pattern was considered as the responsible factor for health advantages. Such pattern was the main focus of study in 1993 at the International Conference on the Diets of the Mediterranean, although the Mediterranean dietary pattern had been previously defined in other meetings (Helsing et al 1989; Serra Majem et al 1993; Nestle et al 1995; Willett et al 1995). Mediterranean dietary patterns are comprised of: abundant plant foods (fruits, vegetables, breads, other forms of cereals, pulses, nuts and seeds); minimally processed, seasonally fresh and locally grown foods; fresh fruits as the typical daily dessert with sweets elaborated from nuts, olive oil and concentrated sugars or honey that are consumed during feast days; olive oil as the principal source of dietary lipids; dairy products (mainly cheese and yoghurt) consumed in low to moderate amounts; fewer than four eggs consumed per week;
red meat consumed in low frequency and amounts; wine consumed in low to moderate amounts, and generally taken with meals. Such a dietary pattern assures a sufficient intake of certain nutrients that have been related in some way with a reduced risk of several chronic diseases. Various scores or indexes have been developed to assess the adherence to the Mediterranean diet pattern in the population and to link such patterns with several nutrient-related diseases (Bach et al 2006).

There is increasing available evidence that following a Mediterranean style diet correlates to higher longevity and delays the onset of the deterioration in health, not only in countries from the Mediterranean Basin but in other non-Mediterranean countries as well (Kouris-Blazos et al 1999; Havenam-Nies et al 2003). However, what ageing people aspire for is not only longer life but also optimal quality of life free of disability or disease that implies being dependent on others. As higher self-rating of health is associated to reduced mortality not only among elderly people but among the general population as well (Idler and Benyamini 1997), identifying which factors contribute to manage healthy aging is key for increasing the percentage of the population who enjoys their longevity. In this context, the relevant question should be: does the Mediterranean diet have any relationship to better self-rated health?

The purpose of this article is to review literature regarding the Mediterranean diet and its effects on healthy aging.

Material and methods
A search of the MEDLINE databases was performed. The keyword “Mediterranean diet” or related term (Mediterranean diet score, Mediterranean dietary pattern) were included as a criterion search. As a second search the following words were included: “cardiovascular disease”, “coronary syndrome”, “dislipaemia”, “blood cholesterol”, “hypertension”, “diabetes”, “obesity”, “overweight”, “waist circumference”, “metabolic syndrome”, “inflammatory markers”, “endothelial function”, “cancer”, “neurodegenerative diseases”, “dementia”, “depression”, “Alzheimer disease”, “mental health”, “health”, “longevity”, “quality of life”.

Only those studies which evaluate the Mediterranean diet as a dietary pattern where taken into account, excluding those which evaluated single food items or nutrients, although they pertain to the Mediterranean dietary pattern. Only studies which included individuals of 65 years or older at the starting point of the study were analyzed. We excluded studies that evaluated the effect of a single Mediterranean Diet meal on the subjects under study and studies conducted in animals. Additional publications were identified from references published in the original papers.

Results
A total of 39 publications were selected, three of them were rejected because they did not accomplish the criterion of inclusion regarding the disorders they investigated. All results are summarized in Table 1. Publications were classified into four groups according to the main outcome they assessed: cardiovascular disease (including risk factors such as high blood pressure, hypercholesterolemia, diabetes, obesity, the metabolic syndrome and inflammatory markers of cardiovascular damage), cancer, mental health (including dementia, Alzheimer’s disease and depression) and longevity and quality of life.

Twenty-one of the studies were about Mediterranean diets and cardiovascular disease, 8 of them being clinical trials. Two of the publications were about Mediterranean diets and cancer, three about Mediterranean diets and mental health and 11 about longevity or mental health. Twenty-two of the publications showed results from Mediterranean countries (Italy, Spain, France, and Greece), 10 from non Mediterranean countries (United Kingdom, Canada, Australia, USA, Denmark, Germany, and The Netherlands) and 4 from multicenter studies in Europe and the United States.

An overwhelming majority of them were beneficial, with very little evidence of null findings and no evidence of harm in any study (Table 1).

Discussion
Since the Seven Countries study publication, an increasing number of studies have supported the beneficial role of the Mediterranean diet on health prevention. There is a rapidly growing recent trend of good-quality observational studies and trials assessing the cardioprotective role of Mediterranean diets (Martinez-González et al 2004). The present review focused on existing evidence for the role of the Mediterranean dietary pattern on aging, or better stated, on successful aging. Modern medicine has managed to add years to life but not to delay the onset of chronic diseases, which implies a greater prevalence of disabilities and dependent people who suffer from any one of the most prevalent chronic diseases. In fact, much of the health-care costs associated to aging are attributed not to chronic disease per se but to activity limitations and all that this represents (Chan et al 2002). The research was restricted to the most prevalent non-communicable diseases leading to disability in older individuals from developed
### Table 1: Characteristics of selected studies about the effectiveness of the Mediterranean diet in the elderly

| Author/year publication | Country   | Type study                  | Population                                                                 | Methodology                                                                 | Outcome               | Results                                                                 |
|-------------------------|-----------|------------------------------|----------------------------------------------------------------------------|------------------------------------------------------------------------------|-----------------------|------------------------------------------------------------------------|
| CVD                     | Greece    | multicenter retrospective case-control study (CARDIO2000) | 848 hospitalized patients (695 M, 58 ± 10 y; 153 F, 65 ± 9 y) a with first event of CHD; 1,078 controls (830 M, 58 ± 10 y; 248 F, 64.8 ± 9 y) | FFQ; 526 patients and 765 controls adopted the Mediterranean-type of diet | BP, TC, blood glucose, BMI | > adherence to the MD = reduction of the coronary risk factors (in hypertensive patients) |
| Scali et al 2001        | France    | cross-sectional              | 989 subjects (473 M, 491 F; 3 age groups: 20–34 y, 35–54 y, 55–76 y)         | FFQ, MDQI                                                                    | BMI                   | in subjects aged 55–75y, > adherence MDQI associated to < % obesity  |
| Martinez-Gonzalez et al 2002 | Spain    | case-control study           | 342 subjects (171 first acute myocardial infarction: 81 M, 90 F; mean age 61.7; controls: 171) | FFQ, MDscore                                                                | BP, TC, blood glucose, BMI | > adherence to the MD = reduction of myocardial infarction risk factors |
| Singh et al 2002        | UK        | RCT, single blind            | 56 subjects (26 M, 30 F; range 57–80 y, mean age 67 ± 1) with average sitting BP: 134/78 ± 3/1 mmHg | 6 w healthy “M-type” diet, 6 w vitamin C supplements, or 6 w placebo         | plasma vitamin C, % dilatation by BK, % dilatation by GTN             | Increase in plasma vitamin C similar with supplements compared with a “healthy diet.” Healthy diet: significant increase in BK-dependent vasodilatation vs placebo (p < 0.011). Healthy diet: significant differences between the 3 study groups in GTN-dependent relaxation (p < 0.011). MD improved vasodilator function in the forearm of healthy older subjects whereas supplementation of vitamin C as tablets had no major effect. Acute intra-arterial vitamin C did not alter dilatation to BK or GTN. Treatment with healthy diet (but not oral vitamin C) improved endothelium-dependent (p = 0.043) and endothelium-independent dilatation (p = 0.011) |
| Barzi et al 2003        | Italy     | clinical trial (GISSI-Prevenzione trial) | 11,323 subjects with MI (M and F; aged 19–90 y, mean age 59 ± 10) | advice to adhere to the MD; Association of food visit and dietary assessment 6th, 18th and 42nd months; clinical visit; dietary questionnaire; diet-score | Association of food intakes (fish, fruit, raw and cooked vegetables and olive oil), a combined dietary score and risk of death | Compared with people in the worst dietary score quartile, odds ratio for people in best score was 0.51. ↑ consumption of each food was associated with ↓ risk of death. MI patients can respond positively to simple dietary advice, and this can be expected to lead to a substantial reduction in the risk of early death. Regardless of any drug treatment prescribed, clinicians should routinely advise patients with myocardial infarction to increase their frequency of consumption of Mediterranean foods |

|-------------------------|---------|------------|------------|-------------|---------|---------|
| Ciccarone et al 2003 | Italy | case-control study | T2DM patients: 144 with PAD (103 M, 41 F; <60 y n:36, 60-69 y n:60, >70 y n:48); 288 without PAD (206 M, 82 F; <60 y n:72, 60-69 y n:120, >70 y n:96) 848 hospitalized patients (695 M, 58 ± 10 y; 153 F, 65 ± 9 y) with a first event of ACS | FFQ, diet-score | BMI, glycated hemoglobin (HbA1c) | > adherence to the MD = significant reduction in PAD risk, independently of diabetes duration and hypertension |
| Pitsavos et al 2003 | Greece | multicenter case-control study (CARDIO2000) | 131 patients (70 M, 61 F; 18 to 80 y; mean age 62.5 ± 9.9) with documented IHD | FFQ, NCEP ATP III | blood pressure, cholesterol level, blood glucose, BMI | > adherence to the MD = reduction of the coronary risk factors (in metabolic syndrome patients) |
| Sondergaard et al 2003 | Denmark | intervention study (unblinded 1-to-1) | 1514 M, 1528 F; 18-89 y. Diabetes Mellitus: 118 M (7.8%), 92 F (6.0%); >65 y M 32 (25.4%), F 40 (31.0%) | FFQ, HEI, DQI-R, RFS, aMED, blood sample | BPT, C, blood glucose, BMI | inverse association between adherence to the MD and prevalence of hypertension, hypercholesterolemia (in both patients and controls) |
| Fung et al 2005 | USA | Nurse’s Health Study | 690 F, 43-69 y, without cardiovascular disease, diabetes or cancer at the time blood was drawn | FFQ, HEI, DQI-R, RFS, aMED, blood sample | BMI; CRP, IL-6, E-selectin, sICAM-1, sVCAM-1 | scores of HEI, DQI-R = lower BMI. > AHEI and aMED scores = reduction in biomarker concentrations (CRP, IL-6, E-selectin) |
| Panagiotakos et al 2005 | Greece | multicenter case-control study (CARDIO2000) | 848 individuals (700 M, 59 ± 10 y; 148 F; 65 ± 9 y; 1078 controls | FFQ | BPT, C, blood glucose, BMI | inverse association between adherence to the MD and prevalence of hypertension, hypercholesterolemia (in both patients and controls) |
| Polychronopoulos et al 2005 | Greece | cohort study | 150 subjects, 65–100 y (53 M, 79 ± 8 y; 97 F, 75 ± 7 y) | FFQ, MD score | TCI, LDL, HDL, TG | inverse association between hypercholesterolemia, alcohol drinking and the adherence to MD |
| Study | Country | Design | Number (M/F; Age) | Inclusion Criteria | Measures | Main Findings |
|-------|---------|--------|------------------|-------------------|----------|--------------|
| Serrano-Martinez et al. 2005 | Spain | case-control study | 24 patients (14 M, 10 F; 61.4 ± 12.6 y) with unstable angina | FFQ, MD score, blood sample | TNF-alpha, VCAM-1 | MED-diet score was inversely associated with the TNF-alpha and VCAM-1. MD may protect against coronary artery wall production of inflammatory mediators |
| Trichopoulou, Orfanos et al. 2005 | Greece | Cohort study (EPIC-Greece) | 23,597 adults (M, F), aged 20–86 y | FFQ, MD score | BMI | adherence to MD was unrelated to BMI in both sexes and was weakly related to WHR only in women |
| Estruch et al. 2006 | Spain | Substudy of a multicenter, randomized, clinical trial of CVD (PREDIMED study) | 772 asymptomatic subjects (M and F; 55–80 y) | Blood sample, MD score | BP, CRP, IL-6, ICAM-1, VCAM-1 | IMD and 2MD vs Low fat diet = < CRP (only IMD), IL-6, ICAM-1, VCAM-1. MD have beneficial effects on cardiovascular risk factors |
| Alvarez Leon et al. 2006 | Spain | Cross-sectional study | 378 subjects (249 M, 329 F; aged > 18 y) | FFQ, anthropometric variables, BP | HOMA index, MD score | MD adherence was not related to MS prevalence, but subjects in the third tertile of adherence presented 70% lower prevalence of the blood pressure criteria and 2.5 times more prevalence of the glycemia criteria with respect to the first tertile |
| Michelsen et al. 2006 | Germany | Clinical trial | 101 patients (59.4 ± 8.6 y, 23% F) with established and treated CAD (80% statins) | FFQ, anthropometric variables, BP, CRP, fibrinogen, homocysteine, fasting insulin, HDL-C, LDL-C, TC, TG | | MD has no effect on markers of inflammation and metabolic risk factors (hs-CRP, fibrinogen, homocysteine, fasting insulin, HDL-C, LDL-C, TC, TG) |
| Panagiotakos, Chrysohoou et al. 2006 | Greece | Greek Study of ACS (the GREECS) | 2172 patients (1,649 M, 65 ± 13 y; 523 F; 72 ± 11 y) with a discharge diagnosis of ACS | FFQ, MD score, blood sample | troponin I, creatine phosphokinase, creatine phosphokinase-MB, BPTC, blood glucose, BMI | inverse correlation between Med-diet score with troponin I, creatine phosphokinase, creatine phosphokinase-MB. MD habits seems to be associated with lower severity of coronary heart disease |
| Estruch et al. 2006 | Spain | Substudy of a multicenter, randomized, clinical trial of CVD (PREDIMED study) | 772 asymptomatic subjects (M and F; 55–80 y) | Blood sample, MD score | BP, CRP, IL-6, ICAM-1, VCAM-1 | IMD and 2MD vs Low fat diet = < CRP (only IMD), IL-6, ICAM-1, VCAM-1. MD have beneficial effects on cardiovascular risk factors |
| Michelsen et al. 2006 | Germany | Clinical trial | 101 patients (59.4 ± 8.6 y, 23% F) with established and treated CAD (80% statins) | FFQ, anthropometric variables, BP, CRP, fibrinogen, homocysteine, fasting insulin, HDL-C, LDL-C, TC, TG | | MD has no effect on markers of inflammation and metabolic risk factors (hs-CRP, fibrinogen, homocysteine, fasting insulin, HDL-C, LDL-C, TC, TG) |
| Panagiotakos, Chrysohoou et al. 2006 | Greece | Greek Study of ACS (the GREECS) | 2172 patients (1,649 M, 65 ± 13 y; 523 F; 72 ± 11 y) with a discharge diagnosis of ACS | FFQ, MD score, blood sample | troponin I, creatine phosphokinase, creatine phosphokinase-MB, BPTC, blood glucose, BMI | inverse correlation between Med-diet score with troponin I, creatine phosphokinase, creatine phosphokinase-MB. MD habits seems to be associated with lower severity of coronary heart disease |
| Estruch et al. 2006 | Spain | Substudy of a multicenter, randomized, clinical trial of CVD (PREDIMED study) | 772 asymptomatic subjects (M and F; 55–80 y) | Blood sample, MD score | BP, CRP, IL-6, ICAM-1, VCAM-1 | IMD and 2MD vs Low fat diet = < CRP (only IMD), IL-6, ICAM-1, VCAM-1. MD have beneficial effects on cardiovascular risk factors |

| Haveman-Nies et al 2003 | multicenter study (Europe) | SENECA study (Survey in Europe on Nutrition and the Elderly: a Concerted Action) | 1,091 M, 1,190 F; 70–75 y | FFQ, MD score | health status measures and lifestyle indicators | high-quality diet (MD), physical activity, non-smoking were related to survival in elderly Europeans |
countries (cardiovascular diseases, certain types of cancer and neurodegenerative diseases) (Lopez et al 2006).

Referring to cardiovascular diseases, the review showed that the Mediterranean diet might exert some effect not only through its impact on the principal risk factors for such diseases but also on the severity of the disease once it appears. Several observational studies (Psaltopoulou et al 2004; Polychronopoulos et al 2005; Panagiotakos, Pitsavos, Chrysobou, et al 2005; Panagiotakos, Pitsavos, Matalas, et al 2005; Fung et al 2005; Serrano Martinez et al 2005; Panagiotakos et al 2006) and intervention studies (Singh et al 2002; Sondergaard et al 2003; Fito et al 2007; Salas-Salvadó et al 2007) have associated the Mediterranean diet pattern to lower levels of blood pressure, blood cholesterol, diabetes, inflammation and improved coagulation process and endothelial function, even in individuals with diabetes (Ciccarone et al 2003) or the metabolic syndrome (Pitsavos et al 2003; Álvarez León et al 2006). Recently, a cross sectional study conducted in Cyprus reported that individuals from 65 to 100 years with a higher adherence to the Mediterranean diet showed lower levels of blood cholesterol even among those treated with statins (Polychronopoulos et al 2005). Moreover, certain observational studies showed that the severity of acute coronary syndrome in hospital death and rehospitalization (the GREECS study, in males aged 65 and women aged 72 years) and the likelihood of having acute coronary syndromes (the CARDIO2000 study, in individuals from 61 ±10 years) were lower among individuals following a Mediterranean style diet (Martínez-González et al 2002; Panagiotakos et al 2005; Panagiotakos et al 2006). These results were in accordance with the findings reported by Lorgeril in the Lyon Heart study or by Barzi in the GISSI Prevezione trial (de Lorgeril et al 1999; Barzi et al 2003). The PREDIMED study, a primary prevention trial conducted in samples of elderly individuals showed that after three months of following a Mediterranean Diet, individuals improved their lipid profile and reduced blood concentrations of inflammatory molecules (Estruch et al 2006; Fito et al 2007).

With respect to obesity, although some observational and prospective studies in younger individuals (Schröder et al 2004; Mendez et al 2006; Panagiotakos et al 2006) reported an inverse relationship with adherence to the Mediterranean diet and BMI and obesity, Trichopoulou’s data of older individuals from the EPIC study (Trichopoulou et al 2005b) and the SUN prospective cohort (Sanchez-Villegas et al 2006) found lower BMI among subjects more adherent to the Mediterranean diet but they did not show any independent significant relationship. In a study comparing...
individuals from the Framingham and the SENECA study, a lower waist circumference and BMI were reported in individuals representing high dietary quality not only for the Mediterranean diet but also for scores evaluating other types of dietary patterns (Havenam-Nies et al 2001). A cross-sectional study conducted in France with a small sample showed that, especially among older individuals, a poor qualification of the Mediterranean Diet Quality index was associated to a higher prevalence of obesity (Scali et al 2001). These results were corroborated in the PREDIMED study, which demonstrated that the intervention did not imply an increase in body weight of participants (Estruch et al 2006). Recent clinical trials have reported benefits of the Mediterranean diet for several aspects of factors related to the incidence or prognosis of cardiovascular disease in individuals with given risk factors such as the diabetic population (Rodriguez Villar et al 2004; Antonopoulou et al 2006), even when relatively high dietary fat content and unrestricted salt intake were permitted.

The metabolic syndrome, a constellation of risk factors for cardiovascular disease, has also been related to the Mediterranean diet, but not without a certain degree of controversy. Data from a cross-sectional study in the Canary Islands in Spain revealed that higher adherence to the Mediterranean diet was not related to a lower prevalence of metabolic syndrome (Álvarez et al 2006). Another cross-sectional study with data from five Mediterranean countries showed no relationship between the Mediterranean diet and the prevalence of the metabolic syndrome (Thanopoulou et al 2006), although a randomized clinical trial from Esposito (Esposito et al 2004) showed that after two years of intervention following a Mediterranean diet, a sample of middle age individuals had reduced the prevalence of metabolic syndrome, inflammatory markers and insulin resistance had declined and endothelial function had improved. On the contrary, another intervention study conducted in Germany showed no impact of adoption of the Mediterranean diet on inflammatory and metabolic risk markers in a sample of patients with coronary artery disease (Michaelsen et al 2006), results that some authors attribute to the study design or the effect the Mediterranean diet had on plasma fatty acid concentrations (Serrano-Martínez and Martínez-González 2007). Moreover, the PREDIMED study did not show a statistically significant relationship between a higher Mediterranean diet score and lower inflammatory biomarkers in the baseline cross-sectional assessment (Salas et al 2007). However, these markers of inflammation significantly improved with the Mediterranean diets after three months of intervention (Estruch et al 2006). There are no cohort studies of Mediterranean diets assessing the incidence of the metabolic syndrome as the outcome.

Adiponectin, a beneficial adipose tissue–secreted cytokine, has been shown to improve insulin sensitivity, to regulate glucose and lipid metabolism, and to have pronounced antiatherosclerotic effects. The levels of circulating plasma adiponectin have been reported to be positively associated with the adherence to a Mediterranean-type dietary pattern among diabetic women (Mantzoros et al 2006).

The role that the Mediterranean diets may have on cancer prevalence has been studied for breast cancer and upper aerodigestive tract cancer. In a cohort of Canadian individuals with a family history of breast cancer or ovarian cancer, no significant association was found between adherence to a Mediterranean diet pattern and risk of BRCA mutation-related breast cancer (Nkondjock and Ghadirian 2007). As the authors stated, alcohol consumption linked to the Mediterranean dietary pattern may have had some effect on such results. On the contrary, data from three case-control studies in Italy showed a reduced risk of cancer of the oral cavity and pharynx, esophagus, and larynx for increasing levels of the Mediterranean diet score (Bosetti et al 2003).

In addition, a four year follow-up of the Lyon Heart study showed a protective effect of the Mediterranean diet for certain cancers (de Lorgeril 1998).

Greater adherence to Mediterranean Diet has been related to improved mental depression, age related cognitive decline and Alzheimer’s disease. Age related cognitive decline has recently been defined as an objective decline in cognitive functioning associated to aging but within the normal limits according to the person’s age. Although defined as a normal process, its progression may be prevented. The Mediterranean dietary pattern may exert its effects on mental health through different mechanisms: ensuring an adequate intake of B vitamins, folate, and Ω-3 fatty acids, which are all involved in the synthesis of certain central nervous system neurotransmitters and phospholipids. In addition, other favorable factors include its effect on vascular mechanisms (lowering certain risk factors such as hypertension, dyslipemia and diabetes or assuring lower homocysteine levels) through its antioxidant properties.

The relationship between Alzheimer’s disease and nutrients are being widely explored (Solfrizzi et al 2003; Luchsinger and Mayeaux 2004) but little data on the relationship with the Mediterranean diet is available. Data from the Washington Heights-Inwood Columbia Aging Project in a non
Mediterranean population showed that higher adherence to the Mediterranean diet was associated with a reduction in the risk for Alzheimer’s disease and a slower cognitive decline, in a dose-response manner, taking into account other confounding factors for Alzheimer’s disease (Scarmeas, Stern, Mayeux, et al. 2006; Scarmeas, Stern, Tang, et al. 2006). After almost nine years of follow up, the Italian Longitudinal Study on Aging showed that a diet high in monounsaturated and polyunsaturated fatty acids was associated with better cognitive performance in elderly individuals following a typical Mediterranean diet (Solfrizzi et al. 2006).

Depression is known to be the leading cause of years of life lived with disability especially among females (López et al. 2006). Few studies have related such disorders with Mediterranean diet adherence. The SUN (Seguimiento Universidad de Navarra) study, a prospective cohort study that analyzed the relationship between dietary intake and some chronic diseases reported an inverse association between vitamin B12 and chronic diseases reported an inverse association between dietary intake and some chronic diseases reported an inverse association between vitamin B12 and chronic diseases reported an inverse association between dietary intake and some chronic diseases reported an inverse association between

Performance in elderly individuals following a typical Mediterranean diet (Waijers et al. 2006). Data from the SENECA and FINE studies conducted (Kafatos et al. 1997). As Barzi et al. (2003) remarks, when simple dietary advice adopted as therapeutic clinical intervention yields the type of results seen in the GIZZI study, such advice should be translated into dietary guidelines and should be addressed not only to coronary patients but to the entire population, especially when such an intervention is as cost-effective as demonstrated (Dalziel et al. 2006). Otherwise, such efforts are naught as there will be no application of the findings in terms of what component/s of the Mediterranean diet is/are responsible for the health effects of such a dietary pattern.
