1. Introduction

The spectral decomposition of the unitary representation $L^2(H \backslash G)$ when $X = H \backslash G$ is a symmetric space has been studied extensively, especially in the case when $G$ is a real Lie group. In particular, through the work of many authors (such as [7], [17], [23], [3] and [1]), one now has the full Plancherel theorem in this setting.

In a recent preprint [20], Sakellaridis and Venkatesh considered the more general setting where $X = H \backslash G$ is a spherical variety and $G$ is a real or p-adic group. Motivated by the study of periods in the theory of automorphic forms and the comparison of relative trace formulas, they formulated an approach to this problem in the framework of Langlands functoriality. More precisely, led by and refining the work of Gaitsgory-Nadler [8] in the geometric Langlands program, they associated to a spherical variety $X = H \backslash G$ (satisfying some additional technical hypotheses)

- a dual group $\hat{G}_X$;
- a natural map $\iota: \hat{G}_X \times SL_2(\mathbb{C}) \to \hat{G}$

The map $\iota$ induces a map from the set of tempered $L$-parameters of $G_X$ to the set of Arthur parameters of $G$, and if one is very optimistic, it may even give rise to a map

$$\iota_*: \hat{G}_X \to \hat{G}$$

where $G_X$ is a (split) group with dual group $\hat{G}_X$ and $\hat{G}_X$ and $\hat{G}$ refer to the unitary dual of the relevant groups. Assuming for simplicity that this is the case, one has the following conjecture:

**Sakellaridis-Venkatesh Conjecture**

One has a spectral decomposition

$$L^2(H \backslash G) \cong \int_{\hat{G}_X} W(\pi) \otimes \iota_*(\pi) d\mu(\pi)$$

where $\mu$ is the Plancherel measure of $\hat{G}_X$ and $W(\pi)$ is some multiplicity space.

In particular, the class of the spectral measure of $L^2(H \backslash G)$ is absolutely continuous with respect to that of the pushforward by $\iota_*$ of the Plancherel measure on $\hat{G}_X$, and its support is contained in those Arthur parameters of $\hat{G}$ which factor through $\iota$. In addition, one expects that the multiplicity space $W(\pi)$ is related to the space of continuous $H$-invariant functionals on the representation $\iota_*(\pi)$.

The main purpose of this paper is to verify the above conjecture in many cases when $H \backslash G$, or equivalently $G_X$, has low rank, and to specify the multiplicity space $W(\pi)$. In particular, we demonstrate this conjecture for many cases when $G_X$ has rank 1, and also some cases when $G_X$ has rank 2 or 3 (see the tables in [20] §15 and §16). More precisely, our main result is:
Theorem 1. The conjecture of Sakellaridis-Venkatesh holds for the spherical varieties $H \backslash G$ listed in the following tables.

| $H \backslash G$ | $GL_{n-1} \backslash GL_n$ | $SO_{n-1} \backslash SO_n$ | $Sp_{2n-2} \backslash Sp_{2n}$ |
|-----------------|---------------------------|---------------------------|---------------------------|
| $G_X$           | $GL_2$                    | $SL_2$                    | $SO(4)$                   |

Table 1. Classical cases

| $H \backslash G$ | $SO_3 \backslash SL_3$ | $Sp_6 \backslash SL_6$ | $SL_3 \backslash G_2$ | $(J, \psi) \backslash G_2$ | $G_2 \backslash Spin_7$ | $G_2 \backslash Spin_8$ | $Spin_9 \backslash F_4$ | $F_4 \backslash E_6$ |
|-----------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|
| $G_X$           | $SL_3$                 | $SL_3$                 | $SL_2$                 | $PGL_3$                | $SL_2$                 | $SL_3^3 / \Delta \mu_2$ | $PGL_2$                | $SL_3$                 |

Table 2. Exceptional cases

We refer the reader to the main body of the paper for the precise statements and unexplained notation.

The theorem is proved using the technique of theta correspondence. More precisely, it turns out that for the groups listed in the above table, one has a reductive dual pair

$$G_X \times G \subset S$$

for some larger group $S$. One then studies the restriction of the minimal representation of $S$ to the subgroup $G_X \times G$. In the context of theta correspondence in smooth representation theory, one can typically show the following rough statement:

A representation $\pi$ of $G$ has $\psi$-generic (and hence nonzero) theta lift to $G_X$ 

\[ \uparrow \]

$\pi$ has nonzero $H$-period.

Our main theorem is thus the $L^2$-manifestation of this phenomenon, giving a description of $L^2(H \backslash G)$ in terms of $L^2(G_X)$.

This idea is not really new: a well known example of this kind of result is the correspondence between the irreducible components of the spherical harmonics on $\mathbb{R}^n$ under the action of $O(n, \mathbb{R})$, and holomorphic discrete series of the group $\widetilde{SL}(2, \mathbb{R})$, the double cover of $SL(2, \mathbb{R})$. Another example is given by the classical paper of Rallis and Schiffmann [18] where they used the oscillator representation to relate the discrete spectrum of $L^2(O(p, q-1) \backslash O(p, q))$ with the discrete series representations of $\widetilde{SL}(2, \mathbb{R})$. Later, Howe [11] showed how these results can be inferred from his general theory of reductive dual pairs, and essentially provided a description of the Plancherel measure of $L^2(O(p, q-1) \backslash O(p, q))$ in terms of the representation theory of $\widetilde{SL}(2, \mathbb{R})$. Then Ørsted and Zhang [27] proved a similar result for the space $L^2(U(p, q-1) \backslash U(p, q))$ in terms of the representation theory of $U(1, 1)$. We give a more streamlined treatment of these classical cases in Section 2, which accounts for Table 1. The rest of the paper is then devoted to the exceptional cases listed in Table 2.

Acknowledgments: Both authors would like to pay tribute to Nolan Wallach for his guidance, encouragement and friendship over the past few years. It is an honor to be his colleague and student respectively. We wish him all the best in his retirement from UCSD, and hope to continue to interact with him mathematically and personally for many years to come.
The research of the first author is partially supported by NSF grant 0801071 and a startup grant from the National University of Singapore.

2. Classical Dual Pairs

We begin by introducing the classical dual pairs.

2.1. Division algebra $D$. Let $\mathbb{k}$ be a local field, and let $|\cdot|$ denote its absolute value. Let $D = \mathbb{k}$, a quadratic field extension of $\mathbb{k}$ or the quaternion division $\mathbb{k}$-algebra, and let $x \mapsto \overline{x}$ be its canonical involution. The case when $D$ is the split quadratic algebra or quaternion algebra can also be included in the discussion, but for simplicity, we shall stick with division algebras. We have the trace map $Tr(x) = x + \overline{x} \in \mathbb{k}$ and the norm map $Q(x) = x \cdot \overline{x} \in \mathbb{k}$.

2.2. Hermitian $D$-modules. Let $V$ and $W$ be two right $D$-modules. We will denote the set of right $D$-module morphisms between $V$ and $W$ by

$$\text{Hom}_D(V,W) = \{T : V \rightarrow W | T(v_1a + v_2b) = T(v_1)a + T(v_2)b \text{ for all } v_1, v_2 \in V, a, b \in D\}.$$

In the same way, if $V$ and $W$ are two left $D$-modules, we set

$$\text{Hom}_D(V,W) = \{T : V \rightarrow W | (av_1 + bv_2)T = a(v_1)T + b(v_2)T \text{ for all } v_1, v_2 \in V, a, b \in D\}.$$

If $V = W$, we will denote this set by $\text{End}_D(V)$. Notice that for right $D$-module morphisms we are putting the argument on the right, while for left $D$-module morphisms we are putting it on the left.

In general, for every statement involving right $D$-modules one can make an analogous one involving left $D$-modules. From now on, we will focus on right $D$-modules, and we will let the reader with the task of making the corresponding definitions and statements involving left $D$-modules. Set

$$\text{GL}(V,D) = \{T \in \text{End}_D(V) | T \text{ is invertible}\}.$$

When it is clear from the context what the division algebra is, we will just denote this group by $\text{GL}(V)$.

Let $V'$ be the set of right $D$-linear functionals on $V$. There is a natural left $D$-module structure on $V'$ given by setting

$$(a\lambda)(v) = a\lambda(v), \text{ for all } a \in D, v \in V, \text{ and } \lambda \in V'.$$

Observe that with this structure, $W \otimes_D V'$ is naturally isomorphic to $\text{Hom}_D(V,W)$ as a $\mathbb{k}$-vector space. Given $T \in \text{Hom}_D(V,W)$, we will define an element in $\text{Hom}_D(W',V')$, which we will also denote $T$, by setting $(\lambda T)(v) := \lambda(Tv)$. This correspondence gives rise to natural isomorphisms between $\text{End}_D(V)$ and $\text{End}_D(V')$ and between $\text{GL}(V)$ and $\text{GL}(V')$.

**Definition 2.** Let $\varepsilon = \pm 1$. We say that $(V,B)$ is a right $\varepsilon$-Hermitian $D$-module, if $V$ is a right $D$-module and $B$ is an $\varepsilon$-Hermitian form, i.e $B : V \times V \rightarrow D$ is a map such that

1. $B$ is sesquilinear. That is, for all $v_1, v_2, v_3 \in V$, $a, b \in D$,$$
   B(v_1, v_2a + v_3b) = B(v_1, v_2)a + B(v_1, v_3)b \quad \text{and} \quad B(v_1a + v_2b, v_3) = \varepsilon B(v_1, v_3) + \overline{B}(v_2, v_3).
$$

2. $B$ is $\varepsilon$-Hermitian. That is,$$
   B(v, w) = \overline{\varepsilon B(w, v)} \quad \text{for all } v, w \in V.
$$

3. $B$ is non-degenerate.
To define left $\varepsilon$-Hermitian $D$-modules $(V, B)$, we just have to replace the sesquilinear condition by
\[
B(av_1 + bv_2, v_3) = aB(v_1, v_3) + bB(v_2, v_3) \quad \text{and} \quad B(v_1, av_2 + bv_3) = B(v_1, v_2)\overline{a} + B(v_1, v_3)\overline{b},
\]
for all $v_1, v_2, v_3 \in V$, $a, b \in D$.

Given a right $\varepsilon$-Hermitian $D$-module $(V, B)$, we will define
\[
G(V, B) = \{g \in GL(V) \mid B(gv, gw) = B(v, w) \text{ for all } v, w \in V\},
\]
to be the subgroup of $GL(V)$ preserving the $\varepsilon$-Hermitian form $B$. When there is no risk of confusion regarding $B$, we will denote this group just by $G(V)$. Usually, $1$-Hermitian $D$-modules are simply called Hermitian, while $-1$-Hermitian $D$-modules are called skew-Hermitian.

Given a right $\varepsilon$-Hermitian $D$-module $(V, B)$, we can construct a left $\varepsilon$-Hermitian $D$-module $(V^*, B^*)$ in the following way: as a set, $V^*$ will be the set of symbols $\{v^* \mid v \in V\}$. Then we give $V^*$ a left $D$-module structure by setting, for all $v, w \in V$, $a \in D$,
\[
v^* + w^* = (v + w)^* \quad \text{and} \quad av^* = (v\overline{a})^*.
\]
Finally, we set
\[
B^*(v^*, w^*) = \overline{B(w, v)} \quad \text{for all } v, w \in V.
\]

In an analogous way, if $V$ is a left $D$-module, we can define a right $D$-module $V^*$, and $V^{**}$ is naturally isomorphic with $V$. Given $T \in \text{End}_D(V)$, we can define $T^* \in \text{End}_D(V^*)$ by setting $v^*T^* := (Tv)^*$. With this definition, it is easily seen that $(TS)^* = S^*T^*$, for all $S, T \in \text{End}_D(V)$. Therefore the map $g \mapsto (g^*)^{-1}$ defines an algebraic group isomorphism between $GL(V)$ and $GL(V^*)$.

Now observe that the form $B$ induces a left $D$-module isomorphism $B^\flat : V^* \to V'$ given by $B^\flat(v^*)(w) = B(v, w)$ for $v, w \in V$. In what follows, we will make implicit use of this map to identify this two spaces. With this identification we can think of $T^*$ as a map in $\text{End}_D(V)$ defined by $v^*(T^*w) := (v^*T^*)(w)$, i.e., $T^*$ is defined by the condition that
\[
B(v, T^*w) = B(Tv, w) \quad \text{for all } v, w \in V.
\]
Observe that this agrees with the usual definition of $T^*$.

A $D$-submodule $X \subset V$ is said to be totally isotropic if $B|_{X \times X} = 0$. If $X$ is a totally isotropic submodule, then there exists a totally isotropic submodule $Y \subset V$ such that $B|_{X \oplus Y \times X \oplus Y}$ is non-degenerate. If we set
\[
U = (X \oplus Y)\perp := \{u \in V \mid B(u, w) = 0 \text{ for all } w \in X \oplus Y\},
\]
then $V = X \oplus Y \oplus U$, and $B|_{U \times U}$ is non-degenerate. In this case we say that $X$ and $Y$ are totally isotropic, complementary submodules. Observe that then $B^\flat|_{Y^*} : Y^* \to X'$ is an isomorphism. As before we will make implicit use of this isomorphism to identify $Y^*$ with $X'$.

2.3. Reductive dual pairs. Let $(V, B_V)$ be a right $\varepsilon_V$-Hermitian $D$-module and $(W, B_W)$ a right $\varepsilon_W$-Hermitian $D$-module such that $\varepsilon_V\varepsilon_W = -1$. On the $\kappa$-vector space $V \otimes_D W^*$ we can define a symplectic form $B$ by setting
\[
B(v_1 \otimes_D \lambda_1, v_2 \otimes_D \lambda_2) = \text{Tr}(B_W(w_1, w_2)B_V^*(\lambda_2, \lambda_1)) \quad \text{for all } v_1, v_2 \in V \text{ and } \lambda_1, \lambda_2 \in V^*.
\]
Let
\[
Sp(V \otimes_D W^*) = \{g \in GL(V \otimes_D W^*, \kappa) \mid B(gv, gw) = B(v, w) \text{ for all } v, w \in V \otimes_D W^*\}.
\]
Observe that
\[
Sp(V \otimes_D W^*) = G(V \otimes_D W^*, B) = G(V \otimes_D W^*).
\]
Moreover, there is a natural map \( G(V) \times G(W) \rightarrow Sp(V \otimes_D W^*) \) given by
\[(g_1, g_2) \cdot v \otimes_D \lambda = g_1 v \otimes \lambda g_2^*.
We will use this map to identify \( G(V) \) and \( G(W) \) with subgroups of \( Sp(V \otimes_D W^*) \). These two subgroups are mutual commutants of each other, and is an example of a reductive dual pair.

2.4. **Metaplectic cover.** The group \( Sp(V \otimes_D W^*) \) has an \( S^1 \)-cover \( Mp(V \otimes_D W^*) \) which is called a metaplectic group. It is known that this \( S^1 \)-cover splits over the subgroups \( G(V) \) and \( G(W) \), except when \( V \) is an odd dimensional quadratic space, in which it does not split over \( G(W) \). In this exceptional case, we shall simply redefine \( G(W) \) to be the induced double cover, so as to simplify notation. We remark also that though the splittings (when they exist) are not necessarily unique, the precise choice of the splittings is of secondary importance in this paper.

2.5. **Siegel parabolic.** Assume in addition that there is a complete polarization \( W = E \oplus F \), where \( E, F \), are complementary totally isotropic subspaces of \( W \). We will use the \( \varepsilon_W \)-Hermitian form \( B_W \) to identify \( F^* \) with \( E^* \) by setting \( f^*(e) = B_W(f, e) \). Observe that this identification induces an identification between \( E^* \) and \( F^* \) given by
\[e^*(f) = \overline{f^*(e)} = B_W(f, e) = \varepsilon_W B_W(e, f).
In what follows, we will use this identifications between \( F^* \) and \( E^* \), and between \( E^* \) and \( F^* \).

Let
\[P = \{p \in G(W) \mid p \cdot E = E\}
be the Siegel parabolic subgroup of \( G(W) \), and let \( P = MN \) be its Langlands decomposition. To give a description of the groups \( M \) and \( N \), we introduce some more notation.

Let \( A \in End_D(E) \). We will define \( A^* \in End_D(F) \), by setting, for all \( e \in E, f \in F \),
\[(1) \quad B_W(e, A^* f) = B_W(Ae, f).
Now given \( T \in Hom_D(F, E) \), define \( T^* \in Hom_D(F, E) \) by setting, for all \( f_1, f_2 \in F \),
\[(2) \quad B_W(f_1, T^* f_2) = \varepsilon_W B_W(Tf_1, f_2).
Given \( \varepsilon = \pm 1 \), set
\[Hom_D(F, E)_\varepsilon = \{T \in Hom_D(F, E) \mid T^* = \varepsilon T\}.
It is then clear that \( Hom_D(F, E) = Hom_D(F, E)_1 \oplus Hom_D(F, E)_{-1} \).

Now we have:
\[M = \left\{ \begin{bmatrix} A \\ (A^*)^{-1} \end{bmatrix} \mid A \in GL(E) \right\} \cong GL(E)
and
\[N = \left\{ \begin{bmatrix} 1 \\ X \end{bmatrix} \mid X^* = -\varepsilon_W X \right\} \cong Hom_D(F, E)_{-\varepsilon_W}.

2.6. **Characters of \( N \).** Given \( Y \in Hom_D(E, F)_{-\varepsilon_W} \), define a character
\[\chi_Y \left( \begin{bmatrix} 1 \\ X \end{bmatrix} \right) = \chi(\text{Tr}_F(YX)).
Here \( \text{Tr}_F \) is the trace of \( YX : F \rightarrow F \) seen as a map between \( \hat{k} \) vector spaces. The map \( Y \mapsto \chi_Y \) defines a group isomorphism between \( Hom_D(F, E)_{-\varepsilon_W} \) and \( \hat{N} \).

Observe that the adjoint action of \( M \) on \( N \) induces an action of \( M \) on \( \hat{N} \). Using the isomorphisms \( M \cong GL(E) \) and \( \hat{N} \cong Hom_D(F, E)_{-\varepsilon_W} \), we can describe the action of \( M \) on \( \hat{N} \) by the formula
\[A \cdot Y = (A^*)^{-1} Y A^{-1} \quad \text{for all} \quad A \in GL(E), \ Y \in Hom_D(F, E)_{-\varepsilon_W}.

Given $Y \in \text{Hom}_D(E,F)_{-\epsilon W}$ we can define a $-\epsilon_W$-Hermitian form on $E$, that we will also denote $Y$, by setting

$$Y(e_1,e_2) = e^*_W(Ye_2) = \epsilon_W B_W(e_1,Ye_2).$$

Hence the action of $M$ on $\hat{N}$ is equivalent to the action of $GL(E)$ on sesquilinear, $-\epsilon_W$-Hermitian forms on $E$.

Let $\Omega$ be the set of orbits for the action of $M$ on $\hat{N}$. Given $Y \in Hom_D(E,F)_{-\epsilon W}$, let $O = \mathcal{O}_Y$ be its orbit under the action of $GL(E)$ and set

$$M_{\chi Y} = \{m \in M \mid \chi_Y(m^{-1}nm) = \chi_Y(n) \text{ for all } n \in N\}.$$

Using the identification of $M$ with $GL(E)$, and of $\hat{N}$ with $\text{Hom}_D(E,F)_{-\epsilon W}$, we see that

$$M_{\chi Y} \cong \{A \in GL(E) \mid (A^*)^{-1}YA^{-1} = Y\} = \{A \in GL(E) \mid Y = A^*YA\}.$$

### 3. Oscillator Representation

After the preparation of the previous section, we can now consider the theta correspondence associated to the dual pair $G(V) \times G(W)$ and use it to establish certain cases of the Sakellaridis-Venkatesh conjecture for classical groups.

#### 3.1. Oscillator representation and theta correspondence

Fix a nontrivial unitary character $\chi$ of $\hat{k}$. Associated to this character, there exists a very special representation of the metaplectic group, called the oscillator representation $\Pi$ of $Mp(V \otimes_D W^*)$. On restricting this representation to $G(V) \times G(W)$, one obtains an injective map

$$\theta : A \subset G(W)^\wedge \longrightarrow G(V)^\wedge$$

and a measure $\mu_\theta$ on $\hat{G}(W)^\wedge$, such that

$$\Pi|_{G(W) \times G(V)} = \int_A \pi \otimes \theta(\pi) d\mu_\theta(\pi),$$

as a $G(W) \times G(V)$-module.

We may restrict $\Pi$ further to $P \times G(V)$. By Mackey theory, for a unitary representation $\pi$ of $G(W)$,

$$\pi|_P = \bigoplus_{\mathcal{O}_Y \in \Omega} \text{Ind}_{M_{\chi Y}N}^P W_{\chi Y}(\pi),$$

where $W_{\chi Y}(\pi)$ is an $M_{\chi Y}N$-module such that $n \cdot \lambda = \chi_Y(n)\lambda$, for all $n \in N$, $\lambda \in W_{\chi Y}(\pi)$. Therefore, from \([3]\) and \([4]\), we have:

$$\Pi = \bigoplus_{\mathcal{O}_Y \in \Omega} \int_{A \subset \hat{G}(W)} \text{Ind}_{M_{\chi Y}N}^P W_{\chi Y}(\pi) \otimes \Theta(\pi) d\mu_\theta(\pi).$$

#### 3.2. The Schrödinger model

On the other hand, we may compute the restriction of $\Pi$ to $P \times G(V)$ using an explicit model of $\Pi$. The complete polarization $\hat{W} = E \oplus F$ induces a complete polarization

$$V \otimes_D W^* = V \otimes_D E^* \oplus V \otimes_D F^*.$$

With the identifications introduced above, $V \otimes_D F^* = \text{Hom}_D(E,V)$, and the oscillator representation $\Pi$ can be realized on the Hilbert space $L^2(\text{Hom}_D(E,V))$; this realization of $\Pi$ is called the Schrödinger model. The action of $P \times G(V)$ in this model can be described as follows.

Let $B_V^P : V \longrightarrow (V^*)'$ be given by

$$(w^*)(B_V^P v) = B_V(w,v).$$
Then the action of \( P \times G(V) \) on \( L^2(\text{Hom}_D(E, V)) \) is given by the formulas

\[
\begin{align*}
(6) \quad \left[ \begin{array}{cc} 1 & X \\ & 1 \end{array} \right] \cdot \phi(T) &= \chi(\text{Tr}_F(\ldots)B_V^\phi T)\phi(T), \quad \text{for all } X \in \text{Hom}_D(F, E) - \epsilon_W, \\
(7) \quad \left[ \begin{array}{cc} A & X \\ (A^*)^{-1} & \end{array} \right] \cdot \phi(T) &= |\det(A)|^{-\dim(V)/2}\phi(TA), \quad \text{for all } A \in \text{GL}(E), \\
(8) \quad g \cdot \phi(T) &= \phi(g^{-1}T), \quad \text{for all } g \in G(V).
\end{align*}
\]

Let

\[ \Omega_V = \{ O_Y \mid O_Y \text{ is open in } \text{Hom}_D(E, F) - \epsilon_W, \text{ and } Y = T^*B_V^\phi T \text{ for some } T \in \text{Hom}_D(E, V) \}. \]

Given \( O_Y \in \Omega_V \), we will set

\[ \mathcal{Y}_Y = \{ T \in \text{Hom}_D(E, V) \mid T^*B_V^\phi T \in O_Y \}. \]

Then

\[ \bigcup_{O_Y \in \Omega_V} \mathcal{Y}_Y \subset \text{Hom}_D(E, V) \]

is a dense open subset, and its complement in \( \text{Hom}_D(E, V) \) has measure 0. Therefore

\[ (9) \quad L^2(\text{Hom}_D(E, V)) \cong \bigoplus_{O_Y \in \Omega_V} L^2(\mathcal{Y}_Y) \]

and each of these spaces is clearly \( P \times G(V) \)-invariant, according to the formulas given in equations (6)-(8).

We want to show that the spaces \( L^2(\mathcal{Y}_Y) \) are equivalent to some induced representation for \( P \times G(V) \). To do this, observe that the "geometric" part of the action of \( P \times G(V) \) on \( L^2(\mathcal{Y}_Y) \) is transitive on \( \mathcal{Y}_Y \). In other words, under the action of \( P \times G(V) \) on \( \text{Hom}_D(E, V) \) given by

\[
\left[ \begin{array}{cc} A & X \\ (A^*)^{-1} & \end{array} \right] \cdot g, T = gTA^{-1} \quad \text{for all } \left[ \begin{array}{cc} A & X \\ (A^*)^{-1} & \end{array} \right] \in P, g \in G(V) \text{ and } T \in \text{Hom}_D(E, V),
\]

each of the \( \mathcal{Y}_Y \)'s is a single orbit. Fix \( T_Y \in \mathcal{Y}_Y \) such that \( T_Y^*B_V^\phi T_Y = Y \). The stabilizer of \( T_Y \) in \( P \times G(V) \) is the subgroup

\[ (P \times G(V))_{T_Y} = \left\{ \left[ \begin{array}{cc} A & X \\ (A^*)^{-1} & \end{array} \right] \cdot g \in P \times G(V) \mid gT_Y = T_YA \right\}. \]

Let \( g \in G(V) \) be such that \( gT_Y = T_YA \) for some \( A \in \text{GL}(E) \). Then by the definition of \( G(V) \)

\[ Y = T_Y^*B_V^\phi T_Y = T_Y^*g^*B_V^\phi gT_Y = A^*YA, \]

that is, \( A \) is an element in \( M_{\mathcal{Y}Y} \).

Define an equivalence relation in \( \text{Hom}_D(E, V) \) by setting \( T \sim S \) if \( T = SA \) for some \( A \in M_{\mathcal{Y}Y} \).

Given \( T \in \text{Hom}_D(E, V) \) we will denote its equivalence class, under this equivalence relation, by \([T]\). Let

\[ P_{M_{\mathcal{Y}Y}}(\text{Hom}_D(E, V)) = \{ [T] \mid T \in \text{Hom}_D(E, V) \}. \]

Since \( G(V) \) acts by left multiplication on \( \text{Hom}_D(E, V) \), there is natural action of \( G(V) \) on the space \( P_{M_{\mathcal{Y}Y}}(\text{Hom}_D(E, V)) \). Set

\[ G(V)_{T_Y} = \{ g \in G(V) \mid gT_Y = T_Y \} \quad \text{and} \quad G(V)_{[T_Y]} = \{ g \in G(V) \mid g[T_Y] = [T_Y] \}. \]
Then \((P \times G(V))_{T_Y} \subset M_{XY} \times G(V)_{[T_Y]},\) and according to equations (6)–(8),
\[
L^2(Y) \cong \text{Ind}_{(P \times G(V))_{T_Y}}^{P \times G(V)} \chi_Y
\]
\[
\cong \text{Ind}^{P \times G(V)}_{M_{XY} \times G(V)_{[T_Y]}} \text{Ind}^{M_{XY} \times G(V)_{[T_Y]}}_{(P \times G(V))_{T_Y}} \chi_Y
\]

Now consider the short exact sequence
\[
1 \rightarrow 1 \times G(V)_{T_Y} \rightarrow (P \times G(V))_{T_Y} \xrightarrow{q} M_{XY} N \rightarrow 1,
\]
where \(q\) is the projection into the first component. Observe that the map \(q\) induces an isomorphism \(G(V)_{T_Y} \setminus G(V)_{[T_Y]} \cong M_{XY}.\) From this exact sequence and equation (11), we get that
\[
L^2(Y) \cong \text{Ind}^{P \times G(V)}_{M_{XY} \times G(V)_{[T_Y]}} L^2(G(V)_{T_Y} \setminus G(V)_{[T_Y]})_{\chi_Y}
\]
\[
\cong \text{Ind}^{P \times G(V)}_{M_{XY} \times G(V)_{[T_Y]}} L^2(G(V)_{T_Y} \setminus G(V))_{\chi_Y}.
\]
The action of \(M_{XY} N\) on \(L^2(G(V)_{T_Y} \setminus G(V)_{[T_Y]})_{\chi_Y}\) is given as follows: \(N\) acts by the character \(\chi_Y\), and \(M_{XY}\) acts on \(L^2(G(V)_{T_Y} \setminus G(V)_{[T_Y]})_{\chi_Y}\) on the left using the isomorphism \(G(V)_{T_Y} \setminus G(V)_{[T_Y]} \cong M_{XY}\). Then according to equations (9) and (12)
\[
L^2(Hom_D(E, V)) \cong \bigoplus_{\mathcal{O}_V \in T_Y} \text{Ind}^{P \times G(V)}_{M_{XY} \times G(V)_{[T_Y]}} L^2(G(V)_{T_Y} \setminus G(V))_{\chi_Y}.
\]

But now, from equations (5), (13) and the uniqueness of the decomposition of the \(N\)-spectrum, we obtain:

**Proposition 3.** As an \(M_{XY} N \times G(V)\)-module,
\[
L^2(G(V)_{T_Y} \setminus G(V))_{\chi_Y} \cong \int_{A \subset \hat{G}(W)} W_{\chi_Y}(\pi) \otimes \Theta(\pi) \, d\mu_\theta(\pi),
\]

Our goal now is to give a more explicit characterization of the spaces \(W_{\chi_Y}(\pi)\) and the measure \(\mu_\theta\) appearing in this formula.

### 3.3. Stable range

Let \((V, B_v)\) and \((W, B_W)\) be as before. Assume now that there is a totally isotropic \(D\)-submodule \(X \subset V\) such that \(\dim_D(X) = \dim_D(W)\); in other words, the dual pair \((G(V), G(W))\) is in the **stable range**. In this case, the map
\[
\theta : \hat{G}(W) \rightarrow \hat{G}(V)
\]
can be understood in terms of the results of Jian-Shu Li [15]. The measure \(\mu_\theta\) appearing in equation (3) is also known in this case: it is precisely the Plancherel measure of the group \(G(W)\). In order to make this paper more self-contained, we will include an alternative calculation of the measure \(\mu_\theta\) using the so-called **mixed model** of the oscillator representation.

### 3.4. Mixed model

Let \(X, Y\) be a totally isotropic, complementary subspaces of \(V\) such that \(\dim_D(X) = \dim_D(W)\), and let \(U = (X \oplus Y)\). We will use \(B_V\) to identify \(Y\) with \((X^*)^\perp\) by setting
\[
(x^*)y = B_V(x, y), \quad \text{for all } x \in X, y \in Y.
\]

Given \(A \in GL(X)\), we can use the above identification to define an element \(A^* \in GL(Y)\) in the following way: given \(x \in X\) and \(y \in Y\), we will set \((x^*)(A^*)y := (x^*A^*)y\), i.e., we will define \(A^* \in GL(Y)\) by requiring that
\[
B_V(x, A^*y) = B_V(Ax, y), \quad \text{for all } x \in X, y \in Y.
\]
Observe that the map $A \mapsto (A^*)^{-1}$ defines an isomorphism between $GL(X)$ and $GL(Y)$. Furthermore if $x \in X$, $y \in Y$ and $A \in GL(X)$, then

$$B_V(Ax, (A^*)^{-1}y) = B_V(x, y).$$

Therefore, we can define a map $GL(X) \times G(U) \to G(V)$ that identifies $GL(X) \times G(U)$ with the subgroup of $G(V)$ that preserves the direct sum decomposition $V = X \oplus Y \oplus U$.

Consider the polarization $V \otimes_D W^* = (X \otimes W^* \oplus U \otimes F^*) \bigoplus (Y \otimes W^* \oplus U \otimes E^*)$. Then as a vector space

$$L^2(X \otimes W^* \oplus U \otimes F^*) \cong L^2(Hom_D(W, X)) \otimes L^2(Hom_D(E, U)).$$

Let $(\omega_U, L^2(Hom_D(E, U)))$ be the Schrödinger model of the oscillator representation associated to the metaplectic group $Sp(U \otimes_D W^*)$. We will identify the space appearing on the right hand side of equation (13) with the space of $L^2$ functions from $Hom_D(W, X)$ to $L^2(Hom_D(E, U))$. This is the so called **mixed model** of the oscillator representation.

The action of $G(W) \times GL(X) \times G(U)$ on this model can be described in the following way: If $T \in Hom_D(W, X)$ and $S \in Hom_D(E, U)$, then

$$g \cdot \phi(T)(S) = [\omega_U(g)\phi(Tg)](S) \quad \forall g \in G(W)$$

$$h \cdot \phi(T)(S) = \phi(T)(h^{-1}S) \quad \forall h \in G(U)$$

$$A \cdot \phi(T)(S) = |\det_X(A)|^{\text{dim} W/2} \phi(A^{-1}T)(S) \quad \forall A \in GL(X).$$

We now want to describe this space as an induced representation. To do this, observe that the set of invertible elements in $Hom_F(W, X)$ forms a single orbit under the natural action of $G(W) \times GL(X)$. Furthermore this orbit is open and dense, and its complement has measure 0. Fix $T_0 \in Hom_F(W, X)$ invertible, and define a $\varepsilon_W$-Hermitian form $B_{T_0}$ on $X$, by setting

$$B_{T_0}(x_1, x_2) = B_W(T_0^{-1}x_1, T_0^{-1}x_2).$$

The group that preserves this form is precisely

$$G(X, B_{T_0}) = \{ T_0gT_0^{-1} \mid g \in G(W) \} \subset GL(X).$$

Let

$$(G(W) \times GL(X))_{T_0} = \{ (g, T_0gT_0^{-1}) \mid g \in G(W) \} \cong G(W)$$

be the stabilizer of $T_0$ in $G(W) \times GL(X)$. Then, according to equations (16)–(18),

$$L^2(W \otimes X) \otimes L^2(Hom_D(E, U)) \cong \text{Ind}_{G(W) \times GL(X)_{T_0}}^{G(W) \times GL(X)} L^2(Hom_D(E, U))$$

$$\cong \text{Ind}_{G(W) \times GL(X)}^{G(W) \times G(X, B_{T_0})} \text{Ind}_{G(W) \times GL(X)_{T_0}}^{G(W) \times G(X, B_{T_0})} L^2(Hom_D(E, U)).$$

Here $(G(W) \times GL(X))_{T_0}$ is acting on $L^2(Hom_D(E, U))$ by taking projection into the first component, and then using the oscillator representation to define an action of $G(W)$ on $L^2(Hom_D(E, U))$. But this representation is equivalent to taking projection into the second component and using the Schrödinger model of the oscillator representation of $Sp(U \otimes X^*)$ (recall that $X$ is equipped with the form $B_{T_0}$) to define an action of $G(X, B_{T_0})$ on $L^2(Hom_D(T_0(E), U))$. Therefore

$$L^2(W \otimes X) \otimes L^2(Hom_D(E, U))$$

$$\cong \text{Ind}_{G(W) \times GL(X)_{T_0}}^{G(W) \times GL(X)} \text{Ind}_{G(W) \times G(X, B_{T_0})}^{G(W) \times G(X, B_{T_0})} L^2(Hom_D(T_0(E), U))$$

$$\cong \text{Ind}_{G(W) \times GL(X)}^{G(W) \times G(X, B_{T_0})} \int_{G(W)} \pi^* \otimes (\pi_{T_0} \otimes L^2(Hom_D(T_0(E), U))) d\mu_{G(W)}(\pi)$$

$$\cong \int_{G(W)} \pi^* \otimes \text{Ind}_{G(X, B_{T_0})}^{GL(X)} \pi_{T_0} \otimes L^2(Hom_D(T_0(E), U)) d\mu_{G(W)}(\pi).$$

(19)
Here $\pi^*$ is the contragredient representation of $\pi$, $\pi^{T_0}$ is the representation of $G(X, B_{T_0})$ given by $\pi^{T_0}(g) = (T_0^{-1}g)T_0$, for all $g \in G(X, B_{T_0})$, and $\mu_{G(W)}$ is the Plancherel measure of $G(W)$. Note that the multiplicity space of $\pi^*$ in (19) is nonzero for each $\pi$ in the support of $\mu_{G(W)}$, i.e. as a representation of $G(W)$, II is weakly equivalent to the regular representation $L^2(G(W))$.

Comparing (3) with (19), we obtain:

**Proposition 4.** If $(G(W), G(V))$ is in the stable range, with $G(W)$ the smaller group, then in equations (3) and (14),

$$A = \hat{G}(W) \quad \text{and} \quad \mu_\theta = \mu_{G(W)}.$$

### 3.5. The Bessel-Plancherel theorem

Finally, we want to identify the multiplicity space $W_{\chi Y}(\pi)$ in (14). Note that this is purely an issue about representations of $G(W)$; a priori, it has nothing to do with theta correspondence. What we know is summarized in the following theorem.

**Theorem 5** (Bessel-Plancherel theorem). Let $(W, B_W)$ be an $\varepsilon_W$-Hermitian $D$-module, and assume that $W$ has a complete polarization $W = E \oplus F$, where $E, F$ are totally isotropic complementary subspaces. Let $P = \{ p \in G(W) \mid p \cdot E = E \}$ be a Siegel parabolic subgroup of $G$, and let $P = MN$ be its Langlands decomposition. Given $\chi \in \hat{N}$, let $O_\chi$ be its orbit under the action of $M$, and let $M_\chi$ be the stabilizer of $\chi$ in $M$. Then

1. For $\mu_{G(W)}$-almost all tempered representation $\pi$ of $G(W)$,

$$\pi|_P \cong \bigoplus_{O_\chi \in \Omega_W} \text{Ind}_{M_\chi N}^G(W_\chi(\pi)).$$

Here $\mu_{G(W)}$ is the Plancherel measure of $G(W)$, $\Omega_W = \{ O_\chi \in \Omega \mid O_\chi \text{ is open in } \hat{N} \}$, and $W_\chi(\pi)$ is some $M_\chi N$-module such that the action of $N$ is given by the character $\chi$.

2. If $O_\chi \in \Omega_W$, then there is an isomorphism of $M_\chi \times G(W)$-modules:

$$L^2(N \backslash G(W); \chi) \cong \int_{\hat{G}(W)} W_\chi(\pi) \otimes \pi \, d\mu_{G(W)}(\pi).$$

(20)

where $W_\chi(\pi)$ is the same space appearing in (1).

3. If $\dim_D(W) = 2$, then for $O_\chi \in \Omega_W$, $\dim W_\chi(\pi) < \infty$ and

$$W_\chi(\pi) \cong Wh_\chi(\pi) = \{ \lambda : \pi^\infty \rightarrow \mathbb{C} \mid \lambda(\pi(n)v) = \chi(n)\lambda(v) \text{ for all } n \in N \},$$

as an $M_\chi N$-module. Here $\pi^\infty$ stands for the set of $C^\infty$ vectors of $\pi$.

4. If $\mathfrak{k}$ is Archimedean, and $M_\chi$ is compact, then

$$W_\chi(\pi) \subset Wh_\chi(\pi)$$

as a dense subspace, and for any irreducible representation $\tau$ of $M_\chi$, one has an equality of $\tau$-isotypic parts:

$$W_\chi(\pi)[\tau] = Wh_\chi(\pi)[\tau].$$

Moreover, this space is finite dimensional.

**Proof.** Part 2 follows from an argument analogous to the proof of the Whittaker-Plancherel measure given by Sakellaridis-Venkatesh [20, §6.3]. For the proof of part 1 observe that, by Harish-Chandra Plancherel theorem

$$L^2(G(W))|_{P \times G(W)} = \int_{\hat{G}(W)} \pi^*|_P \otimes \pi \, d\mu_{G(W)}(\pi).$$
On the other hand
\[ L^2(G(W))|_{P \times G(W)} = \bigoplus_{\mathcal{O}_V \in \Omega_W} \text{Ind}_{M_{X_N}}^{P_{X_N}} L^2(N \setminus G(W); \chi) \]
\[ = \bigoplus_{\mathcal{O}_V \in \Omega_W} \text{Ind}_{M_{X_N}}^{P_{X_N}} \int_{\hat{G}(W)} W_{X_N}(\pi) \otimes \pi d\mu_{G(W)}(\pi) \]
\[ = \int_{\hat{G}(W)} \left[ \bigoplus_{\mathcal{O}_V \in \Omega_W} \text{Ind}_{M_{X_N}}^{P_{X_N}} W_{X_N}(\pi) \right] \otimes \pi d\mu_{G(W)}(\pi). \]
Therefore
\[ \pi^*|_P \cong \bigoplus_{\mathcal{O}_V \in \Omega_W} \text{Ind}_{M_{X_N}}^{P_{X_N}} W_{X}(\pi) \]
for \( \mu_{G(W)} \)-almost all \( \pi \). In the Archimedean case, this result has also been proved in the thesis of the second named author without the \( \mu_{G(W)} \)-almost all restriction, yielding an alternative proof of part 2 for the Archimedean case.

Part 3 was proved by Wallach in the Archimedean case [23], and independently by Delorme, Sakellaridis-Venkatesh and U-Liang Tang in the p-adic case [4, 20, 22]. Finally, Part 4 was shown by Wallach and the second named author in [10].

3.6. **Spectral decomposition of generalized Stiefel manifolds.** We may now assemble all the previous results together. For \( \mathcal{O}_V \in \Omega_W \), the space \( G(V)_{T_Y} \setminus G(V) \) is known as a **generalized Stiefel manifold**. From equations (14) and (19), we deduce:

**Theorem 6.** Suppose that \( G(V)_{T_Y} \setminus G(V) \) is a generalized Stiefel manifold. If, in the notation of equation (20)
\[ L^2(N \setminus G(W); \chi_Y) \cong \int_{\hat{G}(W)} W_{X_N}(\pi) \otimes \pi d\mu_{G(W)}(\pi), \]
then
\[ L^2(G(V)_{T_Y} \setminus G(V)) \cong \int_{\hat{G}(W)} W_{X_Y}(\pi) \otimes \Theta(\pi) d\mu_{G(W)}(\pi). \]
In a certain sense, the last pair of equations says that the Plancherel measure of the generalized Stiefel manifold \( G(V)_{T_Y} \setminus G(V) \) is the pushforward of the Bessel-Plancherel measure of \( G(W) \) under the \( \theta \)-correspondence.

3.7. **The Sakellaridis-Venkatesh conjecture.** Using the previous theorem, we can obtain certain examples of the Sakellaridis-Venkatesh conjecture:

- Taking \( D = \hat{k} \times \hat{k} \) or \( M_2(\hat{k}) \) to be a split \( \hat{k} \)-algebra and \( W \) to be skew-Hermitian with \( \dim_D W = 2 \), we obtain the spectral decomposition of
  \[ H \setminus G = O_{n-1} \setminus O_n, \quad GL_{n-1} \setminus GL_n, \quad Sp_{2n-2} \setminus Sp_{2n}, \]
in terms of the Bessel-Plancherel (essentially the Whittaker-Plancherel) decomposition for \( G_X = GL_2, SL_2, \tilde{SL}_2 \) or \( SO_4 \). This establishes the cases listed in Table 1 in Theorem 1.

- Taking \( D \) to be a quadratic field extension of \( \hat{k} \) or the quaternion division \( \hat{k} \)-algebra, and \( W \) to be skew-Hermitian, we obtain the spectral decomposition of
  \[ H \setminus G = U_{n-1} \setminus U_n, \quad Sp_{n-1}(D) \setminus Sp_n(D). \]
in terms of the Bessel-Plancherel decomposition of \( U_2 \) and \( O_2(D) \). This gives non-split version of the examples above.
In addition, the multiplicity space \( W_\chi(\pi) = Wh_\chi(\pi) \) should be describable in terms of the space of \( H \)-invariant (continuous) functionals on \( \Theta(\pi)^\infty \). Indeed, by the smooth analog of our computation with the Schrödinger model in §3.2, one can show that there is a natural isomorphism of \( M_\chi \)-modules:
\[
W_\chi(\pi) \cong \text{Hom}_H(\Theta^\infty(\pi^\infty), \mathbb{C}).
\]
Here \( \Theta^\infty(\pi^\infty) \) refers to the (big) smooth theta lift of the smooth representation \( \pi^\infty \), i.e. the representation \( \pi^\infty \boxtimes \Theta^\infty(\pi^\infty) \) is the maximal \( \pi^\infty \)-isotypic quotient of the smooth model \( \Pi^\infty = S(\text{Hom}_D(E, V)) \) of the oscillator representation \( \Pi \). One can show using the machinery developed in Bernstein’s paper \([2]\) that for \( \mu_\theta \)-almost all \( \pi \), one has the compatibility of \( L^2 \)-theta lifts (considered in this paper) with the smooth theta lifts:
\[
\Theta(\pi)^\infty \cong \Theta^\infty(\pi^\infty).
\]

With this compatibility, one will obtain
\[
W_\chi(\pi) \cong \text{Hom}_H(\Theta(\pi)^\infty, \mathbb{C}).
\]

3.8. Unstable range. Though we have assumed that \((G(W), G(V))\) is in the stable range from §3.3, it is possible to say something when one is not in the stable range as well. Namely, in §3.4, one could take \( X \) to be a maximal isotropic space in \( V \) (so \( \dim X < \dim W \) here), and consider the mixed model defined on \( L^2(\text{Hom}_D(W, X)) \otimes L^2(\text{Hom}_D(E, U)) \). As an illustration, we note the result for the case when \( W \) is a symplectic space of dimension 2 and \( V \) is a split quadratic space of dimension 3, so that
\[
G(W) \times G(V) \cong SL_2 \times SO_3 \cong SL_2 \times PGL_2.
\]

For a nonzero \( Y \in \hat{N} \), the subgroup \( G(V)_{TV} \) of \( G(V) \) is simply a maximal torus \( A_Y \) of \( PGL_2 \).

**Proposition 7.** We have
\[
L^2(G(V)_{TV} \setminus G(V)) = L^2(A_Y \setminus PGL_2) \cong \int_{\tilde{G}(W)} (W_\chi(\sigma) \otimes W_\chi(\sigma)) \otimes \Theta_\chi(\pi) \, d\mu_{G(W)}(\pi).
\]

We record the following corollary which is needed in the second half of this paper:

**Corollary 8.** The unitary representation \( L^2(\mathfrak{sl}_2) \) associated to the adjoint action of \( PGL_2 \) on its Lie algebra \( \mathfrak{sl}_2 \) is weakly equivalent to the regular representation \( L^2(PGL_2) \).

**Proof.** Since the union of strongly regular semisimple classes are open dense in \( \mathfrak{sl}_2 \), we see that \( L^2(\mathfrak{sl}_2) \) is weakly equivalent to \( \bigoplus_A L^2(A \setminus PGL_2) \), where the sum runs over conjugacy classes of maximal tori \( A \) in \( PGL_2 \). Applying Proposition 7 one deduces that
\[
\bigoplus_A L^2(A \setminus PGL_2) \cong \int_{\tilde{G}(W)} M_\chi(\pi) \otimes \Theta_\chi(\pi) \, d\mu_{G(W)}(\pi)
\]
with
\[
M_\chi(\pi) = W_\chi(\pi) \otimes \bigoplus_A W_{\chi, A}(\pi).
\]

One can show that the theta correspondence with respect to \( \chi \) induces a bijection
\[
\Theta_\chi : \{ \pi \in \tilde{G}(W) : W_\chi(\pi) \neq 0 \} \longleftrightarrow \hat{G}(V).
\]

Moreover, one can write down this bijection explicitly (in terms of the usual coordinates on the unitary duals of \( SL_2 \) and \( PGL_2 \)). From this description, one sees that
\[
(\Theta_\chi)^*(\mu_{G(W)}) = \mu_{G(V)}.
\]
This shows that
\[
\int_{\hat{G}(W)} M_\chi(\pi) \otimes \Theta_\chi(\pi) d\mu_{G(W)}(\pi) \cong \int_{\hat{G}(V)} M_\chi(\Theta_\chi^{-1}(\sigma)) \otimes \sigma d\mu_{G(V)}(\sigma),
\]
with \(M_\chi(\Theta_\chi^{-1}(\sigma)) \neq 0\). This proves the corollary. \(\square\)

4. Exceptional Structures and Groups

The argument of the previous section can be adapted to various dual pairs in exceptional groups, thus giving rise to more exotic examples of the Sakellaridis-Venkatesh conjecture. In particular, we shall show that the spectral decomposition of \(L^2(X) = L^2(H\setminus G)\) can obtained from that of \(L^2(G_X)\), with \(X\) and \(G_X\) given in the following table.

| \(X\) | \(SO_3\setminus SL_3\) | \(SL_3\setminus G_2\) | \((J, \psi)\setminus G_2\) | \(Sp_6\setminus SL_6\) | \(G_2\setminus Spin_7\) | \(G_2\setminus Spin_8\) | \(Spin_9\setminus F_4\) | \(F_4\setminus E_6\) |
|-------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| \(G_X\) | \(SL_3\) | \(SL_2\) | \(PGL_3\) | \(SL_3\) | \(SL_2\) | \(SL_3/\Delta \mu_2\) | \(PGL_2\) | \(SL_3\) |

Table 3.

The unexplained notation will be explained in due course. Comparing with the tables in [20, §15 and §16], we see that these exceptional examples, together with the classical examples treated earlier, verify the conjecture of Sakallaridis-Venkatesh for almost all the rank 1 spherical varieties (with certain desirable properties), and also some rank 2 or rank 3 ones.

Though the proof will be similar in spirit to that of the previous section, we shall need to deal with the geometry of various exceptional groups, and this is ultimately based on the geometry of the (split) octonion algebra \(\mathbb{O}\) and the exceptional Jordan algebra \(J(\mathbb{O})\). Thus we need to recall some basic properties of \(\mathbb{O}\) and its automorphism group. A good reference for the material in this section is the book [12]. One may also consult [16] and [25].

4.1. Octonions and \(G_2\). Let \(\mathfrak{k}\) be a local field of characteristic zero and let \(\mathbb{O}\) denote the (8-dimensional) split octonion algebra over \(\mathfrak{k}\). The octonion algebra \(\mathbb{O}\) is non-commutative and non-associative. Like the quaternion algebra, it is endowed with a conjugation \(x \mapsto \bar{x}\) with an associated trace map \(Tr(x) = x + \bar{x}\) and an associated norm map \(N(x) = x \cdot \bar{x}\). It is a composition algebra, in the sense that \(N(x \cdot y) = N(x) \cdot N(y)\).

A useful model for \(\mathbb{O}\) is the so-called Zorn’s model, which consists of \(2 \times 2\)-matrices
\[
\begin{pmatrix}
  a & v \\
  v' & b
\end{pmatrix},
\]
with \(a, b \in \mathfrak{k}, v \in V \cong k^3\) and \(v' \in V'\),
with \(V\) a 3-dimensional \(\mathfrak{k}\)-vector space with dual \(V'\). Note that there are natural isomorphisms
\[
\wedge^2 V \cong V' \quad \text{and} \quad \wedge^2 V' \cong V,
\]
and let \(\langle -, - \rangle\) denote the natural pairing on \(V' \times V\). The multiplication on \(\mathbb{O}\) is then defined by
\[
\begin{pmatrix}
  a & v \\
  v' & b
\end{pmatrix} \cdot \begin{pmatrix}
  c & w \\
  w' & d
\end{pmatrix} = \begin{pmatrix}
  ac + \langle w', v \rangle & aw + dv + v' \wedge w' \\
  cv' + bw' + v \wedge w & bd + \langle v', w \rangle
\end{pmatrix}
\]
The conjugation map is
\[
\begin{pmatrix}
  a & v \\
  v' & b
\end{pmatrix} \mapsto \begin{pmatrix}
  b & -v \\
  -v' & a
\end{pmatrix}
\]
so that
\[ \text{Tr} \left( \begin{array}{cc} a & v \\ v' & b \end{array} \right) = a + b \quad \text{and} \quad N \left( \begin{array}{cc} a & v \\ v' & b \end{array} \right) = ab - \langle v', v \rangle. \]

Any non-central element \( x \in \mathfrak{O} \) satisfies the quadratic polynomial \( x^2 - \text{Tr}(x) \cdot x + N(x) = 0 \). Thus, a non-central element \( x \in \mathfrak{O} \) generates a quadratic \( \mathfrak{k} \)-subalgebra described by this quadratic polynomial. If this quadratic polynomial is separable, \( x \) is said to have rank 2. Otherwise, \( x \) is said to have rank 1.

The automorphism group of the algebra \( \mathfrak{O} \) is the split exceptional group of type \( G_2 \). The group \( G_2 \) contains the subgroup \( SL(V) \cong SL_3 \) which fixes the diagonal elements in Zorn's model, and acts on \( V \) and \( V' \) naturally. Clearly, \( G_2 \) fixes the identity element \( 1 \in \mathfrak{O} \), so that it acts on the subspace \( \mathfrak{O}_0 \) of trace zero elements. The following proposition summarizes various properties of the action of \( G_2 \) on \( \mathfrak{O}_0 \).

**Proposition 9.** (i) Fix \( a \in \mathfrak{k}^\times \), and let \( \Omega_a \) denote the subset of \( x \in \mathfrak{O}_0 \) with \( N(x) = a \), then \( \Omega_a \) is nonempty and \( G_2 \) acts transitively on \( \Omega_a \) with stabilizer isomorphic to \( SU_3(E_a) \), where \( E_a = \mathfrak{k}[x]/(x^2 - a) \).

(ii) The automorphism group \( G_2 \) acts transitively on the set \( \mathfrak{O}_0 \) of trace zero, rank 1 elements. For \( x \in \mathfrak{O}_0 \), the stabilizer of the line \( \mathfrak{k} \cdot x \) is a maximal parabolic subgroup \( Q = L \cdot U \) with Levi factor \( L \cong GL_2 \) and unipotent radical \( U \) a 3-step unipotent group.

Now we note:

- When \( a \in (\mathfrak{k}^\times)^2 \) in (i), the stabilizer of an element in \( \Omega_a \) is isomorphic to \( SL_3 \); this explains the 2nd entry in Table 3.
- In (ii), the 3-step filtration of \( U \) is given by
  \[ U \supseteq [U, U] \supseteq Z(U) \supseteq \{1\} \]

  where \([U, U]\) is the commutator subgroup and \( Z(U)\) is the center of \( U \). Moreover,
  \[ \dim Z(U) = 2 \quad \text{and} \quad \dim[U, U] = 3, \]

  so that \([U, U]/Z(U) \cong \mathfrak{k}\). If \( \psi \) is a non-trivial character of \( \mathfrak{k} \), then \( \psi \) gives rise to a nontrivial character of \([U, U]\) which is fixed by the subgroup \([L, L] \cong SL_2 \). Setting \( J = [L, L] \cdot [U, U] \), we may extend \( \psi \) to a character of \( J \) trivially across \([L, L]\). This explains the 3rd entry of Table 3.

Though the octonionic multiplication is neither commutative or associative, the trace form satisfies:
\[ \text{Tr}((x \cdot y) \cdot z) = \text{Tr}(x \cdot (y \cdot z)) , \]

(so there is no ambiguity in denoting this element of \( \mathfrak{k} \) by \( \text{Tr}(x \cdot y \cdot z) \)) and \( G_2 \) is precisely the subgroup of \( SO(\mathfrak{O}, N) \) satisfying
\[ \text{Tr}((gx) \cdot (gy) \cdot (gy)) = \text{Tr}(x \cdot y \cdot z) \quad \text{for all } x, y, z \in \mathfrak{O} . \]

4.2. Exceptional Jordan algebra and \( F_4 \). Let \( J = J(\mathfrak{O}) \) denote the 27-dimensional vector space consisting of all \( 3 \times 3 \) Hermitian matrices with entries in \( \mathfrak{O} \). Then a typical element in \( J \) has the form
\[ \alpha = \begin{pmatrix} a & z & \bar{y} \\ \bar{z} & b & x \\ y & \bar{x} & c \end{pmatrix}, \]

with \( a, b, c \in \mathfrak{k} \) and \( x, y, z \in \mathfrak{O} \).

The set \( J \) is endowed with a multiplication
\[ \alpha \circ \beta = \frac{1}{2} \cdot (\alpha \beta + \beta \alpha) \]

Thus, if and only if its entries satisfy

\[ N(x) = bc, \quad N(y) = ca, \quad N(z) = ab, \quad xy = c\overline{z}, \quad yz = a\overline{x}, \quad zx = b\overline{y}. \]

More generally, the above discussion holds if one uses any composition \( \mathfrak{k} \)-algebra in place of \( \mathcal{O} \). Thus, if \( B = \mathfrak{k} \), a quadratic algebra \( K \), a quaternion algebra \( D \) or the octonion algebra \( \mathcal{O} \), one has the Jordan algebra \( J(B) \). One may consider the group \( \text{Aut}(J(B), \det) \) of invertible linear maps on \( J(B) \) which fixes the cubic form \( \det \), and its subgroup \( \text{Aut}(J, \det, e) \) which fixes an element \( e \) with \( \det(e) \neq 0 \). For the various \( B \)'s, these groups are listed in the following table.

| \( B \) | \( \mathfrak{k} \) | \( K \) | \( D \) | \( \mathcal{O} \) |
|---|---|---|---|---|
| \( \text{Aut}(J(B), \det) \) | \( SL_3 \) | \( SL_3(K)/\Delta\mu_3 \) | \( SL_3(D)/\mu_2 = SL_6/\mu_2 \) | \( E_6 \) |
| \( \text{Aut}(J(B), \det, e) \) | \( SO_3 \) | \( SL_3 \) | \( PGS p_6 \) | \( F_4 \) |

Table 4.

**Proposition 10.** (i) For any \( a \in \mathfrak{k}^\times \), the group \( \text{Aut}(J(B), \det) \) acts transitively on the set of \( e \in J \) with \( \det(e) = a \), with stabilizer group \( \text{Aut}(J(B), \det, e) \) described in the above table. If \( e \) is the unit element of \( J(B) \), then \( \text{Aut}(J(B), \det, e) \) is the automorphism group of the Jordan algebra \( J(B) \).

(ii) The group \( F_4 = \text{Aut}(J(\mathfrak{O})) \) acts transitively on the set of rank 1 elements in \( J(\mathfrak{O}) \) of trace \( a \neq 0 \). The stabilizer of a point is isomorphic to the group \( \text{Spin}_9 \) of type \( B_4 \).

In particular, the proposition explains the 1st, 4th, 7th and 8th entry of Table 3.

4.3. **Triality and \( \text{Spin}_8 \).** An element \( \alpha \in J = J(\mathfrak{O}) \) of rank 3 generates a commutative separable cubic subalgebra \( \mathfrak{k}(\alpha) \subset J \). For any such cubic \( F \)-algebra \( E \), one may consider the set \( \Omega_E \) of algebra embeddings \( E \hookrightarrow J \). Then one has:

**Proposition 11.** (i) The set \( \Omega_E \) is non-empty and the group \( F_4 \) acts transitively on \( \Omega_E \).

(ii) The stabilizer of a point in \( \Omega_E \) is isomorphic to the quasi-split simply-connected group \( \text{Spin}^E_8 \) of absolute type \( D_4 \).

(iii) Fix an embedding \( j : E \hookrightarrow J \) and let \( E^\perp \) denote the orthogonal complement of the image of \( E \) with respect to the symmetric bilinear form \( (\alpha, \beta) = \text{tr}(\alpha \circ \beta) \). The action of the stabilizer \( \text{Spin}^E_8 \) of \( j \) on \( E^\perp \) is the 24-dimensional Spin representation, which on extending scalars to \( \overline{\mathfrak{k}} \), is the direct sum of the three 8-dimensional irreducible representations of \( \text{Spin}_8(\overline{\mathfrak{k}}) \) whose highest weights correspond to the 3 satellite vertices in the Dynkin diagram of type \( D_4 \).

As an example, suppose that \( E = \mathfrak{k} \times \mathfrak{k} \times \mathfrak{k} \), and we fix the natural embedding \( E \hookrightarrow J \) whose image is the subspace of diagonal elements in \( J \). Then \( E^\perp \) is naturally \( \mathcal{O} \oplus \mathcal{O} \oplus \mathcal{O} \), and the split group \( \text{Spin}_8 \) acts on this, preserving each copy of \( \mathcal{O} \). This gives an injective homomorphism

\[ \rho : \text{Spin}_8 \rightarrow SO(\mathcal{O}, N) \times SO(\mathcal{O}, N) \times SO(\mathcal{O}, N) \]

whose image is given by

\[ \text{Spin}_8 \cong \{ g = (g_1, g_2, g_3) : \text{Tr}((g_1 x) \cdot (g_2 y) \cdot (g_3 z)) = \text{Tr}(x \cdot y \cdot z) \quad \text{for all } x, y, z \in \mathcal{O} \}. \]
From this description, one sees that there is an action of $\mathbb{Z}/3\mathbb{Z}$ on $Spin_8$ given by the cyclic permutation of the components of $g$, and the subgroup fixed by this action is precisely

$$G_2 = Spin_8^{\mathbb{Z}/3\mathbb{Z}}.$$  

This explains the 6th entry of Table 3.

More generally, the stabilizer of a triple $(x, y, z) \in O^3$ with $(x \cdot y) \cdot z \in \hat{k}^\times$ is a subgroup of $Spin_8$ isomorphic to $G_2$ (see [25]). For example, the stabilizer in $Spin_8$ of the vector $(1, 0, 0) \in O^3$ is isomorphic to the group $Spin_7$ which acts naturally on $O_0 \oplus O \oplus O$. The action of $Spin_7$ on $O_0$ is via the standard representation of $SO_7$, whereas its action on the other two copies of $O$ is via the Spin representation. From the discussion above, we see that the stabilizer in $Spin_7$ of $(x, \bar{x}) \in O^2$, with $N(x) \neq 0$, is isomorphic to the group $G_2$. In particular, this explains the 5th entry of Table 3.

By the above discussion, it is not difficult to show:

**Proposition 12.** The group $Spin_8$ acts transitively on the set of rank 1 elements in $J(O)$ with diagonal part $(a, b, c) \in \hat{k}^\times \times \hat{k}^\times \times \hat{k}^\times$. Moreover, the stabilizer of a point is isomorphic to $G_2$.

### 4.4. $SL_3\backslash G_2$ and $G_2\backslash Spin_7$

From the discussion above, we see that there are isomorphisms of homogeneous varieties

$$SL_3\backslash G_2 \cong SO_6\backslash SO_7 \quad \text{and} \quad G_2\backslash Spin_7 \cong Spin_7\backslash Spin_8 \cong SO_7\backslash SO_8.$$  

Since we have already determined the spectral decomposition of $L^2(SO_6\backslash SO_7)$ and $L^2(SO_7\backslash SO_8)$ in terms of the spectral decomposition of $L^2(SL_2)$ and $L^2(SL_2)$ respectively, we obtain the desired description for $SL_3\backslash G_2$ and $G_2\backslash Spin_7$. Thus the rest of the paper is devoted to the remaining cases in Table 3.

### 5. Exceptional Dual Pairs

In this section, we introduce some exceptional dual pairs contained in the adjoint groups of type $F_4$, $E_6$, $E_7$, and $E_8$. We begin with a uniform construction of the exceptional Lie algebras of the various exceptional groups introduced above. This construction can be found in [19] and will be useful for exhibiting various reductive dual pairs. The reader may consult [16], [19], [21], and [25] for the material of this section.

#### 5.1. Exceptional Lie algebras

Consider the chain of Jordan algebras

$$\hat{k} \subset E \subset J(\hat{k}) \subset J(K) \subset J(D) \subset J(O)$$

where $E$ is a cubic $\hat{k}$-algebra, $K$ a quadratic $\hat{k}$-algebra and $D$ a quaternion $\hat{k}$-algebra. Denoting such an algebra by $\mathcal{R}$, the determinant map det of $J(O)$ restricts to give a cubic form on $\mathcal{R}$. Now set

$$s_{\mathcal{R}} = sl_3 \oplus m_{\mathcal{R}} \oplus (\hat{k}^3 \otimes \mathcal{R}) \oplus (\hat{k}^3 \otimes \mathcal{R})',$$

with

$$m_{\mathcal{R}} = \text{Lie}(Aut(\mathcal{R}, \det)).$$

One can define a Lie algebra structure on $s_{\mathcal{R}}$ [19] whose type is given by the following table.

| $\mathcal{R}$ | $\hat{k}$ | $E$ | $J(\hat{k})$ | $J(K)$ | $J(D)$ | $J(O)$ |
|---------------|-------------|-----|---------------|---------|---------|---------|
| $m_{\mathcal{R}}$ | 0 | $E_6$ | $sl_3$ | $sl_3(K)$ | $sl_6$ | $e_6$ |
| $s_{\mathcal{R}}$ | $g_2$ | $d_4$ | $f_4$ | $e_6$ | $e_7$ | $e_8$ |

We denote the corresponding adjoint group with Lie algebra $s_{\mathcal{R}}$ by $S_{\mathcal{R}}$, or simply by $S$ if $\mathcal{R}$ is fixed and understood.
Let \( \{e_1, e_2, e_3\} \) be the standard basis of \( \hat{\mathfrak{k}}^3 \) with dual basis \( \{e'_i\} \). The subalgebra of \( \mathfrak{sl}_3 \) stabilizing the lines \( \hat{e}_i \) is the diagonal torus \( \mathfrak{t} \). The nonzero weights under the adjoint action of \( \mathfrak{t} \) on \( \mathfrak{s}_R \) form a root system of type \( G_2 \). The long root spaces are of dimension 1 and are precisely the root spaces of \( \mathfrak{sl}_3 \), i.e. the spaces spanned by \( e_i \otimes e_j \). We shall label these long roots by \( \beta, \beta_0 \) and \( \beta_0 - \beta \), with corresponding 1-parameter subgroups
\[
u_\beta(x) = \begin{pmatrix} 1 & x & 0 \\ 1 & 0 & x \\ 1 & 0 & 1 \end{pmatrix}, \quad \nu_{\beta_0}(x) = \begin{pmatrix} 1 & 0 & x \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix}, \quad \nu_{\beta_0-\beta}(x) = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & x \\ 1 & 1 & 1 \end{pmatrix}
\]
We also let
\[
w_\beta = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}
\]
denote the Weyl group element associated to \( \beta \). The short root spaces, on the other hand, are \( e_i \otimes \mathcal{R} \) and \( e'_i \otimes \mathcal{R}' \) and are thus identifiable with \( \mathcal{R} \).

5.2. **Exceptional dual pairs.** We can now exhibit 2 families of dual pairs in \( S_R \).

- From (21), one has \( \mathfrak{sl}_3 \oplus \mathfrak{m}_R \subset \mathfrak{s}_R \).

This gives a family of dual pairs
\[
\mathfrak{sl}_3 \times \text{Aut}(\mathcal{R}, \det) \rightarrow S_R.
\]

- For a pair of Jordan algebras \( \mathcal{R}_0 \subset \mathcal{R} \), we have \( \mathfrak{s}_{\mathcal{R}_0} \subset \mathfrak{s}_R \) which gives a subgroup \( G_{\mathcal{R}_0} \subset S_R \), where \( G_{\mathcal{R}_0} \) is isogeneous to \( S_{\mathcal{R}_0} \). If \( G'_{\mathcal{R}_0, \mathcal{R}} = \text{Aut}(\mathcal{R}, \mathcal{R}_0) \), then one has a second family of dual pairs
\[
G_{\mathcal{R}_0} \times G'_{\mathcal{R}_0, \mathcal{R}} \rightarrow S_R.
\]
With \( \mathcal{R}_0 \subset \mathcal{R} \) fixed, we shall simply write \( G \times G' \) for this dual pair. For the various pairs \( \mathcal{R}_0 \subset \mathcal{R} \) of interest here, we tabulate the associated dual pairs in the table below.

| \( \mathcal{R}_0 \subset \mathcal{R} \) | \( \hat{k} \subset J(K) \) | \( E \subset J(D) \) | \( J(\hat{k}) \subset J(D) \) |
|---|---|---|---|
| \( G \times G' \) | \( G_2 \times \text{PGL}_3 \) | \( \text{Spin}_8 \times \text{SL}_2(E)/\Delta \mu_2 \) | \( F_4 \times \text{PGL}_2 \) |

Observe that in the language of Table 3, with \( X = H \setminus G \), the dual pairs described above are precisely \( G_X \times G \).

5.3. **Heisenberg parabolic.** The presentation (21) also allows one to describe certain parabolic subalgebras of \( \mathfrak{s}_R \). If we consider the adjoint action of
\[
t = \text{diag}(1, 0, -1) \in \mathfrak{sl}_3
\]
on \( \mathfrak{s} \), we obtain a grading \( \mathfrak{s} = \oplus_i \mathfrak{s}[i] \) by the eigenvalues of \( t \). Then
\[
\begin{align*}
\mathfrak{s}[0] &= t \oplus \mathfrak{m} \oplus (e_2 \otimes \mathcal{R}) \oplus (e'_2 \otimes \mathcal{R}') \\
\mathfrak{s}[1] &= \hat{e}_2 \otimes e_1 \oplus (e_1 \otimes \mathcal{R}) \oplus (e'_2 \otimes \mathcal{R}') \oplus \hat{e}'_2 \otimes e_2 \\
\mathfrak{s}[2] &= \hat{e}'_2 \otimes e_1,
\end{align*}
\]
and \( \mathfrak{p} = \oplus_{i \geq 0} \mathfrak{s}[i] \) is a Heisenberg parabolic subalgebra.

We denote the corresponding Heisenberg parabolic subgroup by \( P_S = M_S \cdot N_S \). In particular, its unipotent radical is a Heisenberg group with 1-dimensional center \( Z_S \cong u_{\beta_0}(\hat{k}) \cong \mathfrak{s}[2] \) and
\[
N_S/Z_S \cong \mathfrak{s}[1] = \hat{k} \oplus \mathcal{R} \oplus \mathcal{R}' \oplus \hat{k}.
\]
The semisimple type of its Levi factor \( M_S \) is given in the table below.
The Lie bracket defines an alternating form on $N_S/Z_S$ which is fixed by $P_S^1 = [P_S, P_S]$. This gives an embedding

$$P_S^1 = M_S^1 \cdot N_S \hookrightarrow Sp(N_S/Z_S) \times N_S.$$  

5.4. Intersection with dual pairs. For a pair $R_0 \subset R$, with associated dual pair given in (23), it follows by construction that

$$(G_{R_0} \times G'_{R_0, R}) \cap P_S = P \times G'_{R_0, R},$$

where $P$ is the Heisenberg parabolic subgroup of $G_{R_0}$. On the other hand, for the family of dual pairs given in (22),

$$(SL_3 \times \text{Aut}(R, \det)) \cap P_S = B \times \text{Aut}(R, \det)$$

where $B$ is a Borel subgroup of $SL_3$.

5.5. Siegel parabolic. The group $S$ of type $E_6$ or $E_7$ has a Siegel parabolic subgroup $Q_S = L_S \cdot U_S$ whose unipotent radical $U_S$ is abelian; we call this a Siegel parabolic subgroup. The semisimple type of $L_S$ and the structure of $U_S$ as an $L_S$-module is summarized in the following table.

| $S$ | $L_S$ | $U_S$ | $U_S$ as $L_S$-module |
|-----|-------|-------|-----------------------|
| $E_6$ | $D_5$ | $\mathbb{O} \oplus \mathbb{O}$ | half spin representation of dimension 16 |
| $E_7$ | $E_6$ | $J(\mathbb{O})$ | miniscule representation of dimension 27 |

Let $\Omega_Q \subset \overline{U}_S$ be the orbit of a highest weight vector in $\overline{U}_S$. The following proposition describes the set $\Omega_Q$:

**Proposition 13.** (i) If $S$ is of type $E_6$, then

$$\Omega_Q = \{(x, y) \in \mathbb{O}^2 : N(x) = N(y) = 0 = x \cdot y\}.$$  

(ii) If $S$ is of type $E_7$, then

$$\Omega_Q = \{\alpha \in J : rank(\alpha) = 1\}.$$  

5.6. Intersection with dual pairs. With $R_0 \subset R$ fixed, with associated dual pair $G \times G'$ as given in (23), one may choose $Q_S$ so that

$$(G \times G') \cap Q_S = G \times Q_0$$

with $Q_0 = L_0 \cdot U_0$ a Siegel parabolic subgroup of $G'$, so that $U_0$ is abelian. The group $Q_0$ and the embedding $U_0 \subset U_S$ can be described by the following table.

| $G'$ | $PGL_3$ | $SL_2(E)/\Delta_{\mu_2}$ | $PGL_2$ |
|------|---------|-------------------------|---------|
| $Q_0$ | maximal parabolic | Borel | Borel |
| $U_0 \subset U_S$ | $\mathbb{k}^2 \subset \mathbb{O}^2$ | $E \subset J(\mathbb{O})$ | $\mathbb{k} \subset J(\mathbb{O})$ |

Identifying the opposite unipotent radical $\overline{U}_0$ with the dual space of $U_0$ using the Killing form, one has a natural projection

$$\tau : \overline{U}_S \rightarrow U_0.$$  

This is simply given by the projection from $U_S$ to $U_0$ along $U_0^\perp$. 

| $S$ | $F_4$ | $E_6$ | $E_7$ | $E_8$ |
|-----|------|------|------|------|
| $M_S$ | $C_3$ | $A_5$ | $D_6$ | $E_7$ |
6. Generic Orbits

In this section, we consider an orbit problem which will be important for our applications. Namely, with the notation at the end of the last section, we have an action of \( L_0 \times G \) on the set \( \Omega_Q \subset \mathcal{U}_S \). We would like to determine the generic orbits of this action. For simplicity, we shall consider the case when \( S = E_6 \) and \( E_7 \) separately.

6.1. Dual Pair in \( E_6 \). Suppose first that \( S = E_6 \) so that \( G' \times G = PGL_3 \times G_2 \). In this case, the natural \( L \times G_2 \)-equivariant projection \( \tau : \tilde{U}_S \rightarrow \tilde{U}_0 \) is given by

\[
\tau(x, y) = (Tr(x), Tr(y)).
\]

The nonzero elements in \( \tilde{U}_0 \cong \hat{k}^2 \) are in one orbit of \( L_0 \); we fix a representative \( (0, 1) \in \hat{k}^2 \) and note that its stabilizer in \( L_0 \) is the “mirabolic” subgroup \( L\text{last} \) of \( L_0 \cong GL_2 \). Then the fiber over \((0, 1)\) is given by

\[
\{(x, y) \in \hat{k}^2 : N(x) = N(y) = Tr(x) = 0, Tr(y) = 1, x \cdot \bar{y} = 0\},
\]

and carries a natural action of \( P_{L_0} \times G_2 \). We note:

**Lemma 14.** (i) The group \( G_2 \) acts transitively on the fiber \( \tilde{U}_0 \) and the stabilizer of a point \((x_0, y_0)\) is isomorphic to the subgroup \([L, L] \cdot Z(U) \subset J\).

(ii) If we consider the subset \( \{(x_0, y_0 + \lambda x_0) : \lambda \in \hat{k}\} \subset \tilde{U}_0 \), then the subgroup of \( P_{L_0} \times G_2 \) stabilizing this subset is isomorphic to \( (P_{L_0} \times L \cdot [U, U])^0 = \{h, g \cdot u : \det h = \det g\} \).

The action of the element

\[
\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} \times g \cdot u \in (P_{L_0} \times L \cdot [U, U])^0
\]

is by

\[(x_0, y_0 + \lambda x_0) \mapsto (x_0, y_0 + a^{-1} \cdot (\lambda + b - p(u)) x_0),\]

where \( p : \hat{k} \rightarrow \hat{k} \cong J/[L, L] \cdot Z(U) \) is the natural projection. Thus, there is a unique generic \( L_0 \times G_2 \) orbit on \( \tilde{U}_0 \) given by

\[
(L_0 \times G_2) \times (P_{L_0} \times L \cdot [U, U])^0 \hat{k}.
\]

6.2. Dual Pairs in \( E_7 \). Now suppose that \( S = E_7 \). As above, we first determine the generic \( L_0 \)-orbits on \( \tilde{U}_0 \). For each generic \( L_0 \)-orbit in \( \tilde{U}_0 \), let us take a representative \( \chi \) and let \( Z_\chi \) denote its stabilizer in \( L_0 \). Then the fiber \( \tau^{-1}(\chi) \) is preserved by \( Z_\chi \times G \). In each case, it follows by Prop. [10] (ii) and Prop. [12] that \( G \) acts transitively on \( \tau^{-1}(\chi) \). Denote the stabilizer in \( G \) of \( \tilde{\chi} \in \tau^{-1}(\chi) \) by \( H_\chi \). Then under the action of \( Z_\chi \times G \), the stabilizer group \( \tilde{H}_\chi \) of \( \tilde{\chi} \) sits in a short exact sequence

\[
1 \longrightarrow H_\chi \longrightarrow \tilde{H}_\chi \xrightarrow{p} Z_\chi \longrightarrow 1.
\]

In fact, \( \tilde{H}_\chi \) is a direct product

\[
\tilde{H}_\chi \cong \Delta Z_\chi \times H_\chi \subset Z_\chi \times G
\]

Thus, the generic \( L_0 \times G \)-orbits are given by the disjoint union

\[
\bigcup_{\text{generic } \chi} (Z_\chi \times G) \times \tilde{H}_\chi \tilde{\chi}
\]

where the union runs over the generic \( L_0 \)-orbits on \( \tilde{U}_0 \) and \( \tilde{\chi} \) is an element in \( \tau^{-1}(\chi) \) with stabilizer \( H_\chi \). We summarize this discussion in the following table.
7. Minimal Representation

In this section, we introduce the (unitary) minimal representation $\Pi$ of $S$ and describe some models for $\Pi$. Note that when $S = F_4$, $\Pi$ is actually a representation of the double cover of $F_4$. When $S$ is of type $E$, then $\Pi$ is a representation of $S$.

7.1. Schrodinger model. Because the groups $S = E_6$ and $E_7$ have a Siegel parabolic subgroup, there is an analog of the Schrodinger model for the minimal representation $\Pi$ of $S$. By [6], the representation $\Pi$ can be realized on the space $L^2(\Omega_Q, \mu_Q)$ of square-integrable functions on $Q$ with respect to a $L_S$-equivariant measure $\mu_Q$ on $\Omega_Q$. This is analogous to the Schrodinger model of the Weil representation. In particular, we have the following action of $Q_S$ on $\Pi$:

\[
\begin{aligned}
(l \cdot f)(\chi) &= \delta_{Q_S}(l)^r \cdot f(l^{-1} \cdot \chi) \\
(u \cdot f)(\chi) &= \chi(u) \cdot f(\chi),
\end{aligned}
\]

where $r = 1/4$ (resp. $2/9$) if $S$ is of type $E_6$ (resp. $E_7$).

7.2. Mixed model. For general $S = S_R$, one has the analog of the mixed model, on which the action of the Heisenberg group $P_S$ is quite transparent. Recall that $N_S/Z_S = \hat{k} \oplus R \oplus R' \oplus \hat{k}$ and one has an embedding

$P^S_S = [P_S, P_S] \hookrightarrow \text{Sp}(N_S/Z_S) \times N_S$.

Then by [13], the mixed model of the minimal representation is realized on the Hilbert space

$\text{Ind}_{P^S_S}^{P_S} L^2(R' \oplus \hat{k}') \approx L^2(\hat{k}^\times \oplus R \oplus \hat{k})$,

where the action of $P^S_S$ on $L^2(R \oplus \hat{k})$ is via the Heisenberg-Weil representation (associated to any fixed additive character $\psi$ of $\hat{k}$). The explicit formula can be found in [19 Prop. 43].

In fact, one can describe the full action of $S$ on $\Pi$ by giving the action of an extra Weyl group element. More precisely, if $w_\beta$ is the standard Weyl group element in $SL_3$ associated to the root $\beta$ (see §5.1), then by [19 Prop. 47], one has

$$(w_\beta \cdot f)(t, x, a) = \psi(\det(x)/a) \cdot f(-a/t, x, -a).$$

Since $S$ is generated by $P_S$ and the element $w_0$, this completely determines the representation $\Pi$.

For example, one may work out the action of an element $u_\beta(b) = w_\beta w_\beta b w_\beta^{-1}$ (see §5.1). A short computation gives:

$$(u_\beta(b) \cdot f)(t, x, a) = \psi \left( \frac{b \det(x)}{a - t^2} \right) \cdot f \left( t - \frac{ab}{t}, a - \frac{a^2 b}{t^2}, x \right).$$

If $f$ is continuous, then the above formula gives:

$$(u_\beta(b) \cdot f)(1, x, 0) = \psi(-b \det(x)) \cdot f(1, x, 0).$$

This formula will be useful in the last section.
8. Exceptional Theta Correspondences: $G \times G'$

Now we may study the restriction of the minimal representation $\Pi$ to the dual pairs introduced earlier. In this section, we shall treat the family of dual pairs $G \times G'$ given in [23]. For simplicity, we shall consider the case when $S = E_6$ and $E_7$ separately.

8.1. **Restriction to** $G \times G' \subset E_7$. Suppose first that $S$ is of type $E_7$, so that $\Omega_Q$ is the set of rank 1 elements in $J = J(\mathbb{Q})$. Consider the Schrodinger model for $\Pi$. On restricting $\Pi$ to $Q_0 \times G$, we have the following formulae:

$$\begin{cases}
(g \cdot f)(\alpha) = f(g^{-1} \cdot \alpha) & \text{for } g \in G;
(u(a) \cdot f)(\alpha) = \psi(tr(a \cdot \alpha)) \cdot f(\alpha) & \text{for } u(a) \in U_0;
l \cdot f)(\alpha) = | \det(l) |^s \cdot f(l^{-1} \cdot \alpha) & \text{for } l \in L_0,
\end{cases}$$

where $s$ is a real number whose precise value will not be important to us here.

From our description of generic $L_0 \times G$-orbits given in §6.2, we deduce as in the derivation of [12] that as a $Q_0 \times G$-module,

$$\Pi \cong \bigoplus_{\chi \text{ generic}} \text{Ind}_{U_0 \times H_\chi}^{Q_0 \times G} \chi \boxtimes 1 \cong \bigoplus_{\chi \text{ generic}} \text{Ind}_{Z_\chi \cdot U_0}^{Q_0} L^2(H_\chi \backslash G).$$

Here, $G$ and $Z_\chi$ act on $L^2(H_\chi \backslash G)$ by right and left translation respectively, and $U_0$ acts by $\chi$.

8.2. **Abstract decomposition.** On the other hand, there is an abstract direct integral decomposition

$$\Pi = \int_{G'} \pi \boxtimes \Theta(\pi) \, d\nu_\Theta(\pi).$$

Restricting to $Q_0$, we may write:

$$\pi|_{Q_0} \cong \bigoplus_{\chi} \text{Ind}_{Z_\chi \cdot U_0 \times 1}^{Q_0} \text{Ind}_{Z_\chi \cdot U_0}^{Q_0} W_\chi(\pi)$$

for some $Z_\chi \cdot U_0$-module $W_\chi(\pi)$ with $U_0$ acting via $\chi$. Thus,

$$\Pi \cong \bigoplus_{\chi} \int_{G'} \text{Ind}_{Z_\chi \cdot U_0 \times 1}^{Q_0} \text{Ind}_{Z_\chi \cdot U_0}^{Q_0} W_\chi(\pi) \boxtimes \Theta(\pi) \, d\nu_\Theta(\pi).$$

8.3. **Comparison.** Comparing (25) and (26), we deduce that there is an isomorphism of $G_A$-modules:

$$L^2(H_\chi \backslash G) \cong \int_{G'} \text{Ind}_{Z_\chi \cdot U_0 \times 1}^{Q_0} \text{Ind}_{Z_\chi \cdot U_0}^{Q_0} W_\chi(\pi) \boxtimes \Theta(\pi) \, d\nu_\Theta(\pi).$$

Since $G'$ is isogenous to a product of $SL_2$, the space $W_\chi(\pi) = Wh_\chi(\pi)$ has been determined in Theorem 5.3) and is at most 1-dimensional.

8.4. **Mixed model.** To explicate the measure $d\nu_\Theta(\pi)$, we consider the mixed model of $\Pi$ restricted to $P \times G'$. Since

$$N/Z_S = \hat{\mathbb{k}} \oplus \mathcal{R}_0 \oplus \mathcal{R}_0' \oplus \hat{\mathbb{k}} \subset N_S/Z_S.$$ 

Under its adjoint action on $\mathcal{R} \oplus \hat{\mathbb{k}}$, $G'$ fixes $\mathcal{R}_0 \oplus \hat{\mathbb{k}}$ pointwise, and its action on $\mathcal{R}_0'$ is described in the following table.

| $G'$             | $\mathcal{R}_0$         | $\mathcal{R}_0'$ |
|------------------|-------------------------|------------------|
| $PGL_2$          | $J(\hat{\mathbb{k}})$  | adjoint$^{\text{std}}$ |
| $SL_2/\Delta \mu_2$ | $\hat{\mathbb{k}}^3$ | $\oplus_{i=1}^3 \text{std}_i \boxtimes \text{std}_i^\vee$ |
Thus as a representation of $G'$, we have:

$$\Pi \cong L^2(\hat{\chi}^\times) \otimes L^2(R_0 \oplus \hat{k}) \otimes L^2(R_0^\perp)$$

where $G'$ acts only on $L^2(R_0^\perp)$ and the action is geometric. Thus, $\Pi$ is weakly equivalent to $L^2(R_0^\perp)$ as a representation of $G'$. By our description of the $G'$-module $R_0^\perp$, we have:

**Lemma 15.** The representation $L^2(R_0^\perp)$ (and hence $\Pi$) is weakly equivalent to the regular representation $L^2(G')$

**Proof.** When $G' = PGL_2$, this follows from Corollary 8. When $G' = SL_3^2/\Delta H_2$, the representation of $G'$ on $E_1$ is the restriction of a representation of $G'' = GL_3^2/\Delta \hat{k}^\times$ (by the same formula). Now the action of $G''$ on $R_0^\perp$ has finitely many open orbits with representatives $(1, 1, g) \in GL_3^2$ with $g$ regular semisimple, and the stabilizer of such a representative is $\Delta T$ with $T$ a maximal torus in $PGL_2$. Hence, as a representation of $G''$, $L^2(R_0^\perp)$ is weakly equivalent to

$$\bigoplus_T \text{Ind}_{\Delta T \cdot C} \cong \bigoplus_T \text{Ind}_{\Delta PGL_2} L^2(T \setminus PGL_2)$$

as $T$ runs over conjugacy classes of maximal tori in $PGL_2$. By Corollary 8 and the continuity of induction, we deduce that $L^2(R_0^\perp)$ is weakly equivalent to $L^2(G'')$. Thus, on restriction to $G'$, $L^2(E^\perp)$ is weakly equivalent to $L^2(G')$, as desired. \qed

Concluding, we have:

**Theorem 16.** There is an isomorphism of $G$-modules:

$$L^2(H \setminus G) \cong \int_{G'} W_\chi(\pi) \otimes \Theta(\pi) d\mu_{G'}(\pi),$$

with $W_\chi(\pi) = Wh_\chi(\pi)$ as given in Theorem 3 and $\mu_{G'}$ is the Plancherel measure.

In addition, as we discussed in §3.7, the smooth analog of our argument in this section implies that

$$W_\chi(\pi) = Wh_\chi(\pi) \cong Hom_{H_\chi}(\Theta^\infty(\pi^\infty), C) = Hom_{H_\chi}(\Theta(\pi)^\infty, C).$$

8.5. **Restriction to $PGL_3 \times G_2$.** We now treat the dual pair $PGL_3 \times G_2$ in $S = E_6$, which can be done by a similar analysis. In this case, $\Omega_Q \subset C^2$. If we restrict the action of $S$ to $Q_0 \times G_2$, we deduce by Lemma (ii) that as a representation of $Q \times G_2$,

$$\Pi \cong \text{Ind}_{Q_0 \times G_2}^{P_{L_0} \times L \cdot [U, U]^0} L^2(\hat{k})$$

where the action of $(P_{L_0} \times L \cdot [U, U]^0)$ on $L^2(\hat{k})$ is given through the geometric action described in Lemma (ii) and the action of $U_0$ is by a nontrivial character fixed by $P_{L_0}$.

By using the Fourier transform on $L^2(\hat{k})$, we deduce that as a representation of $(P_{L_0} \times L \cdot [U, U]^0)$,

$$L^2(\hat{k}) \cong \text{Ind}_{U_0 \cdot J}^{(P_{L_0} \times L \cdot [U, U]^0)} \psi^{-1} \otimes \psi.$$

Hence, as a representation of $Q_0 \times G_2$

$$(28) \quad \Pi \cong \text{Ind}_{N_0}^{Q_0} \chi \otimes \text{Ind}_{G_2}^G \psi$$

where $N_0 = U_{L_0} \cdot U_0$ is the unipotent radical of a Borel subgroup of $PGL_3$ and $\chi$ is a generic character of $N_0$.

On the other hand, we have abstractly

$$(29) \quad \Pi \cong \int_{PGL_3} \pi_{Q_0} \otimes \Theta(\pi) d\nu_{E_6}(\pi).$$
We note that if \( \pi \) is tempered, then
\[
\pi|_{Q_0} \cong \text{Ind}_{N_0}^{Q_0} \chi,
\]
in which case we deduce on comparing (28) and (29) that
\[
L^2((J, \psi)\backslash G_2) = \text{Ind}_J^{G_2} \psi \cong \int_{PGL_3} \Theta(\pi) \, d\nu_{PGL_3}(\pi).
\]
For (30) to hold, we thus need to show that \( \nu_{PGL_3} \) is absolutely continuous with respect to the Plancherel measure of \( PGL_3 \).

For this, we examine the mixed model of \( \Pi \) which is realized on \( L^2(\hat{k}^\times \times J(\hat{k}^2) \times \hat{k}) \). Noting that \( J(\hat{k}^2) \cong \mathfrak{sl}_3 \) as \( PGL_3 \)-module [16], we deduce that as a representation of \( PGL_3 \), \( \Pi \) is weakly equivalent to the representation on \( L^2(\mathfrak{sl}_3) \) associated to the adjoint action on \( \mathfrak{sl}_3 \). As in Corollary 8 we know that \( L^2(\mathfrak{sl}_3) \) is weakly equivalent to \( \bigoplus_T L^2(T\backslash PGL_3) \), with \( T \) running over conjugacy classes of maximal tori in \( PGL_3 \).

Using the same argument as in [20, §6], one can show that for each \( T \), the spectral measure for \( L^2(T\backslash PGL_3) \) is absolutely continuous with respect to the Plancherel measure of \( PGL_3 \), and hence so is the spectral measure of \( L^2(\mathfrak{sl}_3) \); this justifies (30) and shows that
\[
L^2((J, \psi)\backslash G_2) = \text{Ind}_J^{G_2} \psi \cong \int_{PGL_3} W(\pi) \otimes \Theta(\pi) \, d\mu_{PGL_3}(\pi)
\]
for some multiplicity space \( W(\pi) \) of dimension \( \leq 1 \).

It is natural to state:

**Conjecture 17.** For an adjoint simple algebraic group \( G \), the representation \( L^2(\mathfrak{g}) \) of \( G \) is weakly equivalent to the regular representation \( L^2(G) \).

Corollary 8 verifies this conjecture for \( PGL_2 \). If the conjecture holds for \( PGL_3 \), one can then take \( W(\pi) \) to be \( \mathbb{C} \) for all \( \pi \).

9. **Exceptional Theta Correspondence:** \( SL_3 \times \text{Aut}(\mathcal{R}, \det) \)

Finally we come to the family of dual pairs \( SL_3 \times \text{Aut}(\mathcal{R}, \det) \subset S = S_5 \) given by (22). What is interesting about this situation is that the group \( S \) may have no Siegel parabolic subgroup, so that the argument below is not the analog of that in the classical cases of §3. To simplify notation, we shall set \( G = \text{Aut}(\mathcal{R}, \det) \). Note that in the case of \( F_4 \), \( S \) is the double cover of \( F_4 \) and the dual pair is \( \tilde{S}L_3 \times \tilde{S}L_3 = \tilde{S}L_3 \times SL_3 \).

Let \( Q_0 = L_0 \cdot U_0 \subset SL_3 \) be the maximal parabolic subgroup stabilizing the subspace \( \hat{k}e_1 + \hat{k}e_2 \), so that
\[
L_0 \cong GL_2 \quad \text{and} \quad U_0 = u_{\beta_0}(-\beta)(\hat{k}) \times u_{\beta_0}(\hat{k}).
\]
Let \( \chi \) be a generic character of \( U_0 \) trivial on \( u_{\beta_0}(-\beta)(\hat{k}) \). The stabilizer in \( L_0 \) of \( \chi \) is a subgroup of the form \( T_0 \times U_{L_0} \) with \( T_0 \cong \hat{k}^\times \) contained in the diagonal torus and \( U_{L_0} = u_{-\beta}(\hat{k}) \). On restricting the minimal representation \( \Pi \) to \( Q_0 \times G \), we may write
\[
\Pi \cong \text{Ind}_{P_{L_0}U_0 \times G}^{Q_0 \times G} \Pi_\chi
\]
for some representation \( \Pi_\chi \) of \( P_{L_0}U_0 \times G \) with \( U_0 \) acting by \( \chi \). Here, we have used the theorem of Howe-Moore which ensures that the trivial character of \( U_0 \) does not intervene.

Now we can describe the \( P_{L_0}U_0 \times G \)-module \( \Pi_\chi \) using the mixed model of \( \Pi \). Recall that this mixed model of \( \Pi \) is realized on \( L^2(\hat{k}^\times \times \mathcal{R} \times \hat{k}) \). Moreover, the action of \( U_0 = u_{\beta_0}(-\beta)(\hat{k}) \times u_{\beta_0}(\hat{k}) \) in...
this model is:

\[
\begin{aligned}
(u_{β_0}(z)f)(t, x, a) &= ψ(tz) \cdot f(t, x, a) \\
(u_{β_0−β}(y)f)(t, x, a) &= ψ(ay) \cdot f(t, x, a).
\end{aligned}
\]

As such, \( \Pi_χ \) is the representation obtained from \( \Pi \) by specializing (continuous) functions \( f \in \Pi \) to the function \( x \mapsto f(1, x, 0) \) of \( \mathcal{R} \). Thus

\[ \Pi_χ = L^2(\mathcal{R}) \]

where the action of \( T_0 \times G \) is geometric, with \( T_0 \) acting by scaling on \( \mathcal{R} \). Moreover, it follows by \cite{24} that the action of \( u−β(b) \in U_{L_0} \) is:

\[ (u_{−β}(b) \cdot f)(x) = ψ(−b \cdot \det(x)) \cdot f(x). \]

Now the set \( \{ x \in \mathcal{R} : \det(x) \neq 0 \} \) is open dense and by Proposition \cite{10}(i), it is the union of finitely many generic orbits of \( T_0 \times G \) indexed by \( \hat{k}^\times / (\hat{k}^\times)^3 \). For each \( a \in \hat{k}^\times / (\hat{k}^\times)^3 \), let \( H_a \) be the corresponding stabilizer group whose type is described in Table 4 in §4.2. Then

\[ \Pi \cong \bigoplus_a \text{Ind}_{Q_0 × H_a}^{G} \chi_a \boxtimes \mathbb{C} \cong \text{Ind}_{Q_0}^{G} \chi_a \boxtimes L^2(H_a \backslash G). \]

On the other hand, one has abstractly

\[ \Pi \cong \int_{SL_3} \pi|_{Q_0} \otimes Θ(π) dν_θ(π). \]

Now we note:

**Lemma 18.** As a representation of \( SL_3 \), \( \Pi \) is weakly equivalent to \( L^2(SL_3) \).

**Proof.** If \( S \) is of type \( E \), the group \( SL_3 \) is contained in a conjugate of the Heisenberg parabolic subgroup \( P_S \). Indeed, after an appropriate conjugation, we may assume that

\[ SL_3 \subset \text{Aut}(J(\hat{k}^2), \text{det}) = SL_3 \times_{μ_3} SL_3 \subset \text{Aut}(J(B), \text{det}), \]

where \( B = \hat{k}^2 \), \( M_2(\hat{k}) \) or the split octonion algebra \( \mathbb{O} \) in the respective case. From the description of the mixed model, one sees that \( \Pi \) is nearly equivalent to the representation of \( SL_3 \) on \( L^2(J(B)) = L^2(J(\hat{k}^2)) \otimes L^2(J(\hat{k}^2)^{⊥}). \) Since \( J(\hat{k}^2) \cong M_3(\hat{k}) \) with \( SL_3 \) acting by left multiplication, we see that \( J(\hat{k}^2) \) is weakly equivalent to the regular representation of \( SL_3 \). This implies that \( \Pi \) is weakly equivalent to the regular representation of \( SL_3 \).

The case when \( S = F_4 \) is a bit more intricate; we omit the details here. \( \square \)

Thus \( ν_θ = μ_{SL_3} \) and every \( π \) in the support of \( ν_θ \) is tempered, so that

\[ π|_{Q_0} = \bigoplus_{a ∈ \hat{k}^\times/(\hat{k}^\times)^3} Wh_{χ_a}(π) \otimes \text{Ind}_{Q_0}^{Q_0} χ_a. \]

Comparing, we see that

\[ L^2(H_a \backslash G) \cong \int_{SL_3} Wh_{χ_a}(π) \otimes Θ(π) dμ_{SL_3}(π), \]

as desired.
