ABSTRACT

Background: Chronic non-communicable diseases, including cardiovascular diseases (CVDs), have caused many deaths worldwide. Atherosclerotic plaque formation is common in individuals with CVDs. Thus, antioxidant and anti-inflammatory nutritional strategies can be used to prevent or inhibit this process. Due to its higher concentrations of cocoa, dark chocolate is considered a functional food due to the presence and action of phytochemical compounds, with anti-inflammatory and antioxidant actions. However, the recommended amounts of these compounds to prevent atherosclerosis have not yet been fully elucidated.

Aim: The aim of the study was to review the effects of cocoa and dark chocolate intake on the prevention of cardiovascular dysfunction and atherosclerosis.

Methods: This narrative review was based on a search of PubMed and Lilacs. The search was conducted from September 2021 to February 2022 using the following keywords: flavonoids, cocoa, atherosclerosis, oxidative stress, and inflammation. The inclusion criteria were original articles, meta-analyses, and experimental and clinical studies published between 2002 and 2022 in English, focusing on the subject addressed. The exclusion criteria were the title and abstract reading and duplication of articles in the databases.

Results: The antioxidant and anti-inflammatory functions of phytochemicals in cocoa and dark chocolate are related to the modulation of nitric oxide through activation/phosphorylation and acting as a vasodilator. Furthermore, these phytochemicals reduce the formation of reactive oxygen species and activate antioxidant enzymes. The anti-inflammatory activities are related to the modulation of nuclear factor kappa B in the reduction of inflammatory markers, such as tumor necrosis factor-alpha, C-reactive protein, and pro-inflammatory cytokines, as well as in the reduction of adhesion molecules in the wall of the vas.

Conclusion: The main phytochemicals present in cocoa and dark chocolates are catechins and their epicatechin isomers, which are responsible for improving inflammatory, metabolic, and antioxidant profiles. Its consumption can be encouraged, but with caution, owing to the caloric supply and forms of chocolate production, as these factors can reduce the presence of flavonoids in its composition.

Relevance for Patients: The antioxidant and anti-inflammatory functions of the phytochemicals in cocoa and dark chocolate are responsible for modulating nitric oxide via activation/phosphorylation and acting as a vasodilator. Reducing the formation of reactive oxygen species, as well as activating antioxidant enzymes. As for the anti-inflammatory activities, they modulate the nuclear factor kappa B, reducing inflammatory markers, thus improving the antioxidant and inflammatory profile of these patients.
1. Introduction

Chronic non-communicable diseases (NCDs) have a multifactorial etiology, which is determined by genetic factors and modifiable factors, such as eating habits, smoking, obesity, and sedentary lifestyle [1, 2]. NCDs, including cardiovascular diseases (CVDs), have caused a larger number of deaths worldwide. According to data from the World Health Organization, for which global statistics were calculated, approximately 44% of all deaths are related to chronic NCDs, accounting for seven of the ten main causes of death worldwide [3].

In the pathophysiological process of CVDs, the formation of atherosclerotic plaques is common in all cases [4]. Cardiovascular episodes are mainly associated with unstable plaques and their ruptures, which have intense inflammatory activity and highly thrombogenic lipid material, presenting themselves as a determining factor in the clinical manifestations of atherosclerosis [4]. Excessive production of reactive oxygen species (ROS) results in oxidative stress, which is related to atherosclerosis [5].

Thus, antioxidant and anti-inflammatory nutritional strategies can be used as allies for the prevention or reduction of atherogenesis [6]. Some foods, such as fruits, vegetables, teas, red wine, and dark chocolate, have characteristics that offer health benefits due to the action of their bioactive compounds [7].

Cocoa present in chocolates, particularly in dark chocolates, is rich in flavonoids associated with benefits for cardiovascular health [8]. These benefits are related to antioxidant action, increased insulin sensitivity, decreased platelet aggregation, lower expression of adhesion molecules, and activation of nitric oxide, a potent vasodilator that helps reduce blood pressure [9].

Despite several studies addressing the benefits of the antioxidant and anti-inflammatory action of dark chocolate or cocoa, there are still inconsistencies regarding the phytochemicals present in this food, the benefits of its consumption, and the adequate amount to be ingested. Thus, this study aimed to review the literature how the phytochemicals present in cocoa and dark chocolate modulate the atherogenesis process, and consequently, prevent atherosclerosis.

2. Methodology

This is a narrative review based on a search of PubMed, Scopus, Web of Science, SciElo, and Lilacs. The search was performed from September 2021 to February 2022, using the following keywords: flavonoids, cocoa, atherosclerosis, oxidative stress, and inflammation. The inclusion criteria were original articles, meta-analyses, and experimental and clinical studies published between 2002 and 2022 in English, focusing on the subject addressed. The exclusion criteria were the title and abstract reading and duplication of articles in the databases. The selection was initially made by one author and later by a second author.

3. Phytochemicals in Cocoa

At present, cocoa is one of the most consumed products worldwide and is widely used by the food industry [10]. There are at least three groups of substances in cocoa beans with beneficial health effects: (i) flavonoids (catechin and proanthocyanidins), (ii) theobromine/caffeine, and (iii) minerals (magnesium, iron, and zinc) [11]. It is known that the term flavonoids is considered the generic name for all compounds included in the subfamilies, such as flavanols, flavones, flavanones, and flavanols (ex: catechin), anthocyanins, and iso-flavones [12]. Because they are contained in cocoa, in this study, the class of greatest interest was flavonols.

The basic chemical structure of flavonoids consists of two aromatic rings, A and B, connected by an oxygenated heterocycle C, with flavanols being the predominant forms (+)-epicatechin, (+)-epicatechin, (-)-catechin, and (+)-catechins (monomeric), procyanidins (oligomeric), and proanthocyanidins [13]. They are known to be composed of catechins, procyanidins, and procyanidins or condensed tannins that are formed from the bond between (+) monomers, catechin, and (-)-epicatechin, allowing the formation of catechin dimers, oligomers, and polymers [14].

According to Rothwell (2013), the flavanols with the highest concentrations in cocoa are epicatechins, followed by catechins. How much the dimeric procyanidins, Ottaviani et al. (2012) suggested that their role as a mediator of beneficial effects to the organism contributes little to the systemic pool of flavonoids, and their bioactivity is related to the generation of phenolic metabolites after biotransformation by the intestinal microbiota [15].

In addition to polyphenols, cocoa contains theobromine (approximately 2 – 3% of the bean weight), a plant alkaloid of the methylxanthine family, with antioxidant potential, which acts on the central nervous system [16]. According to Sansone et al. (2016), theobromine positively affects the absorption of epicatechins, showing the synergism between the bioactive compounds present in cocoa [17].

Several factors can influence the type and amount of flavonoids present in foods containing cocoa and chocolate, including the geographic origin of cocoa production, type of cultivation, harvesting, post-harvest, and processing practices [18]. Studies performed with the Kuna Indians, natives of islands off the coast of Panama, and consumers of large amounts of cocoa per day showed that the Kuna Indians have lower blood pressure values compared to other Pan-American civilizations [19]. The factors involved are environmental and not genetic, as this cardiovascular protection was lost by the Kuna Indians who migrated to the urban part of Panama City, where cocoa consumption was replaced by other foods low in flavonoids [20].

In addition, Schroeter et al. (2006) found that urinary levels of flavanol metabolites expressed as epicatechin equivalents are more than 6 times higher in island dwellers off the coast of Panama, who consumed approximately 600 – 900 mg of flavonoids per day compared to inhabitants of the western continent [21].

A study by Ottaviani et al. (2015) evaluated the safety and efficacy of consuming cocoa flavonoids in healthy adults and concluded that ingestion in amounts of up to 2000 mg/day in 12 weeks had no adverse effects on the health of men and women [22]. In Europe, the estimated average intake of flavonoids from cocoa is 105 mg/day [23]. Thus, it is possible to observe that flavonoid intake varies widely according to geographic location.
4. Properties of the Phytochemical Compounds of Cocoa

4.1. Anti-inflammatory activity

The anti-inflammatory mechanisms of phytochemical compounds in cocoa have not yet been fully elucidated. Several benefits of flavanol (-)-epicatechin (EC) from cocoa have been attributed to its antioxidant and anti-inflammatory properties. Ruizters et al. (2014) investigated whether EC can prevent the deterioration of the anti-inflammatory effect of glucocorticoid cortisol (GC) in the presence of oxidative stress. Cortisol reduces inflammation in differentiated monocytes. Oxidative stress quenches the anti-inflammatory effects of cortisol, leading to cortisol resistance. EC reduces intracellular oxidative stress and the development of cortisol resistance. Thus, it was possible to prove the mechanism by which EC exerts its anti-inflammatory and antioxidant action [24].

In addition, cocoa consumption leads to a reduction in the levels of inflammatory markers and pro-inflammatory molecules. Jafariirad et al. (2018) observed that 84% cocoa dark chocolate supplementation reduced inflammatory markers such as high-sensitivity C-reactive protein (hs-CRP), tumor necrosis factor-alpha (TNF-α), and interleukin-6 (IL-6) in type 2 diabetic patients [25].

Sarria et al. (2014) concluded that regular consumption of a fiber-rich cocoa product containing 416.4 mg of polyphenols for 4 weeks decreased plasma concentrations of the cytokines IL-1b and IL-10 while slightly reducing other concentrations of molecules pro-inflammatory [26]. Eskandari et al. (2020) observed similar results, as well as a reduction in leptin, resistin, and monocyte chemoattractant protein 1 (MCP-1), and an increase in the concentration of adipokines with anti-inflammatory properties such as irisin and adiponectin [27].

Another aspect in which the anti-inflammatory activity of cocoa is related to the modulation of the synthesis of eicosanoids is through the action of prostanoids, which inhibit the action of 5-lipoxygenase (LOX-5) through MAPK kinase, an enzyme involved in the synthesis of leukotrienes, with arachidonic acid as its precursor [28]. Inhibition of LOX-5 confers anti-inflammatory, vasoprotective, and anti-bronchoconstrictor effects. Furthermore, Alvarez-Cilleros et al. (2020) believed that the anti-inflammatory properties are mainly related to modulation via intracellular phosphorylation of nuclear factor kappa B (NF-κB), and found that cocoa ingestion prevents its phosphorylation, as well as increased regulation of nitric oxide synthase (iNOS) in the rat aorta, thus supporting the anti-inflammatory effect of cocoa [29].

4.2. Effects of cocoa phytochemicals on atherosclerosis

The accumulation of fat in the arterial walls is associated with low-density lipoproteins (LDLs), which, due to the increase in intimal permeability, favor their retention in the subendothelial space, causing an inflammatory process through adhesion molecules such as molecule cell adhesion-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1), E-selectin, and MCP-1 [30]. Such molecules promote migration, adhesion, and accumulation of lymphocytes and monocytes in the arterial wall, which a posteriori differentiate into macrophages and capture oxidized LDLs [29,31].

According to Khan et al. (2012), the consumption of 40 g of dark chocolate can modulate the lipid profile, increase high-density lipoprotein (HDL) levels, and reduce oxidized low-density lipoprotein (LDL) levels in patients with high cardiovascular risk [32]. This is an important role of cocoa polyphenols in lipid metabolism, as they bind to LDL particles, inhibit oxidation [32,33], and reduce platelet aggregation. This is supported by Innes et al. (2003), who observed that ingestion of 100 g of dark chocolate reduced platelet aggregation and adhesion [34].

Endothelial nitric oxide synthase (eNOS) is one of the most prominent pathways in the atherosclerotic process and is responsible for the production of nitric oxide, which is important for the preservation of vascular health, with an action proportional to cell function. Therefore, the lower the availability of NO, the lower its function [35]. In addition, it is known that foods with a high flavonoid content can stimulate the production of NO [36].

In addition, some studies have analyzed the bioactivity of metabolites such as acid 3,4-dihydroxyphenylacetic acid (DHPAA), 2,3-dihydroxybenzoic acid (DHBA), and 3-hydroxyphenylpropionic acid (HPPA) generated by the intestinal microbiota from flavonols, which were able to improve endothelial function and prevent oxidative stress in human endothelial cells [37].

Vázquez-Agell et al. (2013) evaluated the activation of NF-κB and adhesion molecules (ICAM, VCAM, and E-selectin) in 18 healthy volunteers, measured 6 h before and after consumption of 40 g of cocoa powder. They observed a significant reduction in NF-κB activation and ICAM-1 concentration when consumed with water, and no change when consumed with milk. In addition, there was a significant increase after the milk-only intervention; E-selectin decreased only after the intervention with cocoa and water. No significant change was observed in VCAM-1 concentration, confirming the action of cocoa in reducing NF-κB [38] (Table 1).

Thus, according to studies carried out with cocoa, it was possible to observe an improvement in the lipid profile and inflammatory mediators, reducing NF-κB and adhesion molecules. In studies performed with chocolate, a reduction in adhesion molecules and an increase in nitric oxide were observed. The amount of chocolate and the percentage of cocoa were very heterogeneous, making it difficult to establish a precise recommendation. Finally, regarding the levels of phytochemicals present in both samples, there was no pattern of analysis, and it is still undetermined which associations and quantities would be recommended to obtain these effects. It is important to note that chocolate should be consumed with caution.

According to Counet. et al. (2004), among the factors that can influence the type and amount of flavonoids present in cocoa and chocolate, processing must be considered since the main interest during chocolate processing is to preserve the nutrients that occur naturally in cocoa beans. Thus, food processing methods, such as fermentation and baking, can decrease the final flavonoid content [18].

Among the studies of this review, it is important to emphasize that some evaluated the flavonoids present in cocoa but did not establish the total content of this polyphenol. Others only evaluated the percentages of cocoa concentration, which is one of the limitations of this review that most of the studies found that the concentration of cocoa in chocolate was considered. Therefore, few studies have considered flavonoids in milligrams, which is considered a bias in studies to better understand the number of
milligrams of this compound available in the cocoa consumed by individuals. Thus, further studies are needed to carry out this conversion and quantify the flavonoids in cocoa.

5. Conclusion

Studies have shown that the main phytochemicals present in cocoa and dark chocolates are catechins and their epicatechin isomer, which are responsible for attenuating the atherosclerotic process, reducing the activation of NF-κB, adhesion molecules, and pro-inflammatory cytokines, and increasing the levels of anti-inflammatory cytokines such as IL-10. They also help reduce fasting blood glucose and glycated hemoglobin and improve the lipid profile with a reduction in LDL and triglycerides and an increase in HDL. They also modulate some hormones of the reward system and exert antioxidant actions. Therefore, its consumption should be encouraged, but with caution due to the caloric supply and forms of chocolate production, as these factors can reduce the presence of flavonoids in their composition. Quantification of these bioactive compounds should be encouraged to complete the recommendation of the percentage of cocoa in chocolate.
