ABSTRACT

In this study, cobalt diselenide (CoSe$_2$) and the composites (CoSe$_2$@RGO) of CoSe$_2$ and reduced graphene oxide (RGO) were synthesized by a facile hydrothermal reaction using cobalt ions and selenide source with or without graphene oxide (GO). The formation of CoSe$_2$@RGO composites was identified by analysis with X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), Raman spectroscopy and scanning electron microscopy (SEM). Electrochemical analyses demonstrated that the CoSe$_2$@RGO composites have excellent catalytic activity for the reduction of I$_3^-$, possibly indicating a synergetic effect of CoSe$_2$ and RGO. As a consequence, the CoSe$_2$@RGO composites were applied as a counter electrode in DSSC for the reduction of redox couple electrolyte, and exhibiting the comparable power conversion efficiency (7.01%) to the rare metal platinum (Pt) based photovoltaic device (6.77%).

Keywords: CoSe$_2$, Alternative Catalyst, DSSCs, Counter Electrode, Metal Chalcogenide

1. Introduction

Since the breakthrough work by Grätzel and O’Regan in 1991, dye-sensitized solar cells (DSSCs) have been formulated like a sandwich configuration that consists of photoanode, electrolyte, and counter electrode (CE) [1]. Unlike silicon-based solar cells, electrons generated by light illumination in DSSCs are transported via electrochemical reactions, and thus called electrochemical devices. In specific, Pt is the most widely used material as the catalyst for the reduction of redox couple electrolyte of DSSCs due to its superior electrocatalytic properties and chemical stability against an iodide/triiodide (I$^-$/I$_3^-$)-based electrolyte [2].

A lot of efforts have been devoted to develop alternative catalytic materials for expensive rare metal platinum (Pt) [3-4]. Although cost-effective carbon-based materials including carbon black, carbon nanotube, graphite, and graphene have exhibited stable chemical stability, unique structural features, and electronic properties, they do not possess catalytic activities as high as Pt [5-6]. Recently, metal chalcogenide (MC) materials have emerged as a potential candidate for the electrochemical and catalytic applications [7]. The MCs have a composition of MX, where M= a transition metal, X= chalcogen (S, Se, and Te), and their physical and chemical properties vary according to the sort of M and X. MCs have been utilized in a wide range of fields such as transistors, energy conversion, and storage devices [8]. Many kinds of MCs have been also applied to DSSCs as the catalyst materials for the reduction of redox couple electrolyte [9]. Cobalt sulfide (CoS) was employed as a CE material of DSSCs for the first time by Wang et al. [10], exhibiting similar electrocatalytic effects like Pt, and low charge transfer resistance corresponding to 1.8 $\Omega$cm$^2$. After that, FeS$_2$ [11], Ni$_{0.85}$Se [12], NiSe$_2$ [13], and other MCs have been used to catalyst materials for the CE of DSSCs whose devices showed superior performances with low charge transfer resistance. Here, we have scrutinized RGO and cobalt diselenide (CoSe$_2$), which are broadly suited in cataly-
sis research. They are highly sensitive to catalytic reaction and conductive to deliver carries to optimal sites. They are also very cheap and easily scalable when industrial demands are existing.

In this study, CoSe$_2$ and the composites (CoSe$_2$@RGO) of CoSe$_2$ and reduced graphene oxide (RGO) were synthesized by a facile hydrothermal reaction using cobalt ions and selenide source with or without graphene oxide (GO). CoSe$_2$ supported by carbon derivatives has been studied as a prospective material for rechargeable aluminum-ion batteries (RAIBs) [14] and catalyst for the oxygen reduction reaction [15], exhibiting good catalytic effects and stability. Herein, the composite of CoSe$_2$@RGO is utilized as the CE of DSSCs for I$_3^-$ reduction. Electrochemical analyses demonstrated that the CoSe$_2$@RGO composites have excellent catalytic activity for the reduction of I$_3^-$, possibly indicating a synergetic effect of CoSe$_2$ and RGO. As a consequence, the CoSe$_2$@RGO composites based devices exhibited comparable power conversion efficiencies (7.01%) to the rare metal platinum (Pt) based photovoltaic device (6.77%).

2. Experimental

2.1 Synthesis of CoSe$_2$, CoSe$_2$@RGO and RGO

CoSe$_2$ was synthesized via a facile hydrothermal reaction. Selenium (Se) precursor solution (solution A) was prepared by dissolving 4 g of sodium hydrox-ide (NaOH, Aldrich, 99% anhydrous) in 30 ml of deionized water (DI water) followed by adding 0.32 g of selenium powder (Se, Aldrich, 99.999% metal basis) at 80°C to dissolve Se, completely. Cobalt (Co) precursor solution (solution B) was prepared by dissolving 0.31 g of ethyldiaminetetraacetic acid disodium salt dihydrate (EDTA-2Na, Sigma-Aldrich, 99.0-101.0%) in 10 ml of DI water with vigorous stirring for a few minutes followed by adding 0.48 g of cobalt chloride hexahydrate (CoCl$_2$·6H$_2$O, Alfa Aesar, 99.9% metal basis). After heating the solution B at the same temperature of the solution A, the solution B was slowly poured into the solution A, and the mixed solution was further stirred for 10 min on a heated hot plate. Then, the precursor solution was transferred to a Teflon-lined autoclave, and heated at 170°C for 2 h. After cooling down to room temperature naturally, the black precipitate was obtained and washed several times with water and ethanol. Finally, the product was dried in a vacuum oven at 60°C for overnight.

In the case of CoSe$_2$@RGO, the whole synthesis procedure was similar to CoSe$_2$ synthesis but a solution C was added. 2.6 mg of graphene oxide (GO) sheets was uniformly dispersed by ultra-sonication in 8 ml of DI water to form the solution C.

To compare the CoSe$_2$@RGO composites, RGO was also synthesized by using a hydrothermal method. 30 mg of GO in 60 ml of DI water was treated in an ultrasonic bath for 30 min and the dispersed solution was transferred to an autoclave. The hydrothermal reaction was conducted at the same condition for the synthesis of cobalt diselenide derivatives. The precipitation was washed several times, then completely dried at 60°C.

2.2 Preparation of TiO$_2$ photoanode

Fluorine-doped tin oxide (FTO) glass substrates (TEC, 8 Ω, Pilkington) were cleaned with a detergent solution and then cleaned in an ultrasonic bath using ethanol, acetone, and 2-propanol for 10 min, respectively. After UV-treatment for 20 min, TiO$_2$ paste (ENB Korea, 20 nm) was coated on the substrates by a doctor-blade method. The resulting layer was sintered at 500°C for 2 h in a muffle furnace. The TiO$_2$-coated substrates were immersed in 0.3 mM of an N719 dye solution (a mixture of tert-butanol and acetonitrile in a volume ratio of 1:1) for 24 h at room temperature.

2.3 Preparation of counter electrode

CoSe$_2$ and CoSe$_2$@RGO powder were dispersed in γ-butyrolactone (GBL, Sigma-Aldrich, 99%) at a 0.7 mg/ml, 1.3 mg/ml and 2 mg/ml concentration. Then, the dispersion was drop-casted onto UV-cleaned 3 cm × 4 cm size FTO glass at the amount of 10 μg/cm$^2$, 20 μg/cm$^2$ and 30 μg/cm$^2$. The substrates were dried in an ambient condition naturally for overnight and then thermal treated at 200°C for several minutes. For the comparison, RGO powder was also dispersed in GBL at 1.3 mg/ml concentration. The subsequent process was the same as the preparation of CoSe$_2$ with/without RGO CE. In the case of the platinized CE, 7 mM of chloroplatinic acid hexahydrate (H$_2$PtCl$_6$, Sigma-Aldrich) solution in 2-propanol (IPA) was prepared and the solution was drop-casted onto the FTO substrates, and then sintered at 400 °C for 1 h. The final loading amount of Pt and RGO was fitted at 20 μg/cm$^2$. 

Yohan Ko et al. / J. Electrochem. Sci. Technol., 2019, 10(3), 313-320
2.4 Device fabrication
Treated 3 cm × 4 cm size anode and cathode were cut into 1.5 cm × 2.0 cm. Two kinds of electrodes were combined using hot-melt Surlyn (Solaronix, 60 μm) spacer. After that, iodide/triiodide redox shuttle electrolyte was injected through a pre-drilled hole and the holes were sealed by a thin cover glass. The electrolyte composition was 1-hexyl-2,3-dimethylimidazolium iodide (0.6 M), iodine (0.03 M), guanidinium thiocyanate (0.1 M), and 4-tert-butylpyridine (0.5 M) in acetonitrile.

2.5 Characterization
X-ray diffraction measurement was carried out using Cu Kα radiation (λ = 0.154 nm) (D8 Advance, Bruker). Scanning electron microscopy (SEM) images of CoSe₂ and CoSe₂@RGO were taken using FESEM (FE-SEM, Hitachi S-4800 and Nova NanoSEM 230). Raman spectra were obtained using micro-Raman spectrometer (Alpha 300R) excited at 633 nm laser source. Surface chemical state were investigated using X-ray photoelectron spectroscopy (XPS, K-alpha, Thermo Fisher). Electrochemical impedance spectroscopy (EIS) and Tafel polarization measurements were performed with symmetrical dummy cells, which were filled with the same electrolyte used in DSSCs. EIS were conducted in a frequency range of 10⁻² to 10⁶ Hz. The Nyquist plot were fitted using Z-view software. Cyclic voltammetry (CV) measurements were carried out in a three-electrode using a Pt-mesh as a CE and a Ag/Ag⁺ electrode as a reference electrode in a electrolyte solution (0.1 M of LiClO₄, 0.01 M LiI, and 1 mM I₂ in acetonitrile). Current density-voltage (J-V) curves of DSSCs with different CEs were obtained using potentiostat under 100 mW/cm² AM 1.5G light (ABET Technology, LS 150 simulator). All the electrochemical characterizations were performed with electrochemical station (Bio-Logic, VSP).

3. Results and Discussion
To characterize the phase and structures of the as-synthesized materials, X-ray diffraction (XRD) measurements were performed on CoSe₂@RGO, CoSe₂, reduced graphene oxide (RGO), and graphene oxide (GO). The XRD patterns of GO exhibited a peak at 11.3°, corresponding to an interplanar spacing of 0.78 nm. The XRD patterns of the hydrothermal
treated GO showed a broad peak of RGO at 23.1°, corresponding to an interplanar spacing of 0.38 nm. The XRD patterns of the as-synthesized CoSe$_2$@RGO showed a peak of RGO at 23.1°. Moreover, the peak intensities of the CoSe$_2$@RGO became weak, and the phase intensities were changed, compared to the pure CoSe$_2$, suggesting that the RGO have an effect on the formation of CoSe$_2$, and possibly mixed via hydrothermal reaction [16]. The XRD patterns of the as-synthesized CoSe$_2$ and CoSe$_2$@RGO were compared to the standard XRD data of CoSe$_2$ (JCPDS no. 00-053-0449) in Supporting Information (SI) Fig. S1. To compare the morphology of CoSe$_2$ and CoSe$_2$@RGO, SEM image characterization were conducted on the samples shown in Fig. S2. The synthesized CoSe$_2$ has tiny nanorod-based shape, while CoSe$_2$@RGO has another kind of CoSe$_2$ crystal like sheet shape with tiny nanorod-based CoSe$_2$.

To further confirm that an RGO phase in the CoSe$_2$@RGO composite, we performed Raman characterization on the CoSe$_2$ and CoSe$_2$@RGO. The Raman spectra of the CoSe$_2$ and CoSe$_2$@RGO are shown in Fig. 1b. The peak at 171 cm$^{-1}$ in both samples represents the bending of Se-Se bonds in the close-packed chains [17]. By contrast, the CoSe$_2$@RGO sample contains two peaks at 1328 and 1587 cm$^{-1}$. These peaks are known as defect band (D-band, 1328 cm$^{-1}$), and graphitic band (G-band, 1587 cm$^{-1}$), which are usually observed in GO and RGO. The intensity of D-band to G-band (I$_D$/I$_G$) observed in the CoSe$_2$@RGO exhibited 1.10 of I$_D$/I$_G$, which implies that GO was converted into RGO via hydrothermal reaction with the formation of CoSe$_2$ compounds [18].

X-ray photoelectron spectroscopy (XPS) measurements were performed on the as-synthesized CoSe$_2$ and CoSe$_2$@RGO. Fig. 1c represents the XPS spectra for Co 2p, and Fig. 1d does for Se 3d. The XPS spectra peaks correspond to Co 2p$_{3/2}$ at 778.5 eV, Co 2p$_{1/2}$ at 793 eV, Se 3d$_{5/2}$ at 54.6 eV, and Se 3d$_{3/2}$ at 55.3 eV, respectively [19].

These results are well consistent with reported CoSe$_2$ [19]. Fig. 2 demonstrates the XPS spectra of GO, RGO, CoSe$_2$, and CoSe$_2$@RGO for C 1s. In the case of RGO, the peaks related to oxygen bond significantly decreased compared to GO, pointing out that a large number of functional groups associated with oxygen were removed via hydrothermal reaction, and thus converted to RGO [16]. In addition, the C-O peaks at around 286.6 eV in CoSe$_2$@RGO were not as strong as the GO sample, which proves that GO in the CoSe$_2$@RGO were converted to RGO via hydrothermal reaction. Also, the relative peak intensity of carbon-carbon bond for the CoSe$_2$@RGO is

![Fig. 2. X-ray photoelectron spectroscopy spectra of (a) GO, (b) RGO, (c) CoSe$_2$, and (d) CoSe$_2$@RGO for C 1s.](image-url)
higher than the CoSe$_2$. On the other hand, the intensity of Co and Se is similar in both samples. It is evident from the results that the CoSe$_2$@RGO is surely composed of carbon derivatives that have a less of carbon-oxygen bond groups.

To investigate catalytic performances of the as-synthesized materials, electrochemical analyses were conducted with F-doped SnO$_2$ (FTO) electrodes coated of Pt, RGO, CoSe$_2$, and CoSe$_2$@RGO. Cyclic voltammetry (CV) curves of various samples can be found in Fig. 3a. Two pairs of the peaks corresponding to the oxidation and reduction of iodide (I$^-$) and triiodide (I$_3^-$) were observed [20], the oxidation and reduction reaction of the I species are given in eqn (1) and (2):

\[
3I^- \rightarrow I_3^- + 2e^- \text{ (oxidation)} \tag{1}
\]
\[
I_3^- + 2e^- \rightarrow 3I^- \text{ (reduction)} \tag{2}
\]

The difference between the voltages of the left pair peaks was compared to evaluate the catalytic performance in DSSCs of materials. The peak-to-peak separation ($E_{pp}$) of the left pair for the Pt, CoSe$_2$, and CoSe$_2$@RGO based electrodes was 0.639 V, 0.585 V, and 0.432 V, respectively. The $E_{pp}$ of the RGO based electrode was not clearly determined owing to the ambiguousness of its reduction peak from I$_3^-$ to I$^-$.

The CoSe$_2$@RGO based electrode that shows the lowest $E_{pp}$ values exhibited better electrocatalytic performances than the others.

Electrochemical impedance spectroscopy (EIS) measurement was performed to examine the interfacial electrochemical properties, using symmetric dummy cells of the as-synthesized materials. Nyquist plots of Pt, RGO, CoSe$_2$, and CoSe$_2$@RGO are illustrated in Fig. 3b. The first semicircles of the plots present the charge transfer resistance ($R_{ct}$) at the electrodes/electrolyte interface. Thus, $R_{ct}$ is directly linked to the electrocatalytic effects of materials and the number of catalytic sites. The $R_{ct}$ of the Pt, RGO, CoSe$_2$, and CoSe$_2$@RGO based devices was 0.61 $\Omega$cm$^2$, 0.14 $\Omega$cm$^2$, 0.50 $\Omega$cm$^2$, and 0.20 $\Omega$cm$^2$, respectively, indicating that the CoSe$_2$@RGO preserves more active catalytic sites for I$^-\text{ reduction}$ [12]. The second semicircle at low-frequency region arising from Nernst diffusion impedance (or Warburg impedance, $Z_w$) of the electrolyte species had the value of 1.90 $\Omega$cm$^2$, 6.75 $\Omega$cm$^2$, 0.50 $\Omega$cm$^2$, and 0.20 $\Omega$cm$^2$, respectively, indicating that the CoSe$_2$@RGO preserves more active catalytic sites for I$^-\text{ reduction}$ [12]. The second semicircle at low-frequency region arising from Nernst diffusion impedance (or Warburg impedance, $Z_w$) of the electrolyte species had the value of 1.90 $\Omega$cm$^2$, 6.75 $\Omega$cm$^2$, 0.50 $\Omega$cm$^2$, and 0.20 $\Omega$cm$^2$, respectively, indicating that the CoSe$_2$@RGO preserves more active catalytic sites for I$^-\text{ reduction}$ [12]. The second semicircle at low-frequency region arising from Nernst diffusion impedance (or Warburg impedance, $Z_w$) of the electrolyte species had the value of 1.90 $\Omega$cm$^2$, 6.75 $\Omega$cm$^2$, 0.50 $\Omega$cm$^2$, and 0.20 $\Omega$cm$^2$, respectively, indicating that the CoSe$_2$@RGO preserves more active catalytic sites for I$^-\text{ reduction}$ [12].

Fig. 3. (a) Cyclic voltammetry curves of Pt, CoSe$_2$, CoSe$_2$@RGO, and RGO scanned at a rate of 50 mV/s. (b) Nyquist plots for symmetric dummy cells of Pt, CoSe$_2$, CoSe$_2$@RGO, and RGO. The inset shows the corresponding Nyquist plots at a magnified scale. (c) Tafel polarization curves for symmetric dummy cells of Pt, CoSe$_2$, CoSe$_2$@RGO, and RGO scanned at a rate of 10 mV/s and (d) magnified cathodic branches.
the CoSe$_2$ based electrodes have the superior electrocatalytic activity to the Pt based electrode. Equivalent circuit and fitted results for the EIS measurement are provided in Fig. S2.

To further elucidate the electrocatalytic activity of the as-synthesized materials, Tafel polarization measurement was conducted with the symmetric cells. Fig. 3c shows the Tafel polarization curves. The slope of Tafel zone at the middle potentials with a sharp slope can be considered as exchange current density ($J_0$) [10]. The $J_0$ can be derived from the function of $R_{ct}$, as described in the following eqn (3):

$$J_0 = \frac{RT}{nF R_{ct}}$$

Where $R$ is the gas constant, $T$ is the absolute temperature, $n$ is the number of electrons involved in the reduction of I$_3^-$ to I$^-$, and $F$ is Faraday’s constant. Thus, the slope of the Tafel zone is inversely correlated to $R_{ct}$, and the slopes of the Pt, RGO, CoSe$_2$, and CoSe$_2$@RGO based devices revealed that the CoSe$_2$@RGO based device shows a superb charge-transfer performance compared to the control group, which is consistent with the result of the EIS analysis.

The $D_{I}$ of I$_3^-$ reduction in the redox couple can be expressed with the limiting current density ($J_{lim}$) at the high voltage zone with the y-axis [21], which is derived from the following eqn (4):

$$J_{lim} = \frac{2nFCD_l}{l}$$

Where $n$ is the number of electrons involved in the reaction, $F$ is Faraday’s constant, $l$ is the spacer thickness, and $C$ is the I$_3^-$ concentration. The result from the $J_{lim}$ is consistent with that from the $Z_w$, which was obtained from the EIS analysis. This Tafel polarization study revealed that the CoSe$_2$ and CoSe$_2$@RGO based CE have the comparable electrocatalytic performance to the Pt based CE in the reduction process of I$_3^-$ to I$^-$ of the redox couple.

Fig. 4 shows the current density-voltage ($J-V$) curves of DSSCs fabricated with counter electrodes of the as-synthesized materials measured under one-sun illumination, and their photovoltaic parameters are summarized in Table 1. The loading amount of the as-synthesized materials onto counter electrodes was adjusted by varying the precursor concentration. The summarized results of photovoltaic parameters according to the loading amount of catalyst materials are provided in Fig. S3. For all the electrodes, quite comparable catalytic reaction at the counter electrode was shown. However, RGO electrode showed very high series resistance which is appeared in FF value, and CoSe$_2$ only electrode showed lower photovoltage than both of the materials are applied. Although clear reason is not given at this moment, advantages of both RGO and CoSe$_2$ could be utilized when both of materials are combined. When the loading amount is increased to 30 mg/cm$^2$, FF and current densities are

![Fig. 4. Current density-voltage characteristics of dye-sensitized solar cells fabricated with different counter electrodes measured under one-sun illumination (100 mW/cm$^2$).](image)

| Counter electrodes | $J_{sc}$ (mA/cm$^2$) | $V_{oc}$ (V) | FF | Efficiency (%) |
|-------------------|----------------------|--------------|----|----------------|
| Pt                | 13.12                | 0.765        | 0.67| 6.77           |
| CoSe$_2$          | 12.95                | 0.773        | 0.65| 6.47           |
| CoSe$_2$@RGO      | 12.24                | 0.792        | 0.72| 7.01           |
| RGO               | 12.11                | 0.761        | 0.40| 3.66           |
lowered only to show lower performance. Loading of high concentration of the composite may cause their coming off the electrode, and this may affect electrolyte system. Similar phenomena are observed when carbon black composite has been applied [22].

The DSSC of RGO based CE exhibited the lowest performances, mainly because of low fill factor (FF, 0.40), possibly connected to the high charge transfer resistance at the electrolyte/CE interface. On the other hand, the DSSC of CoSe₂@RGO based CE represented the best efficiency (η) of 7.01% with an open circuit voltage (V_{oc}) of 0.792, an FF of 0.72, and a short circuit current density (J_{sc}) of 12.24 mA/cm², which is higher than the η of 6.77% of the Pt based CE photovoltaic (V_{oc}=0.762 V, FF=0.67 and J_{sc}=13.12 mA/cm²). The enhanced parameters of DSSC were attributed to the superior electrocatalytic activity of the CoSe₂@RGO, and these results suggest that the composites of CoSe₂ with RGO can be a promising alternative material to the rare metal Pt.

4. Conclusions

In summary, we presented a facile approach to synthesize CoSe₂@RGO composites using a hydrothermal reaction. The formation of CoSe₂@RGO were confirmed by XRD, XPS, FE-SEM and Raman analyses. Electrocatalytic activities of CoSe₂ derivatives were examined compared to rare metal Pt based counter electrode. Electrochemical analyses such as EIS, CV, and Tafel polarization demonstrated that CoSe₂@RGO has excellent electrocatalytic effects for the reduction of triiodide (I₃⁻) to iodide (I⁻) due to its low charge transfer resistance (R_{ct}), which is lower than Pt based electrode device. DSSCs using the CoSe₂@RGO material as a catalyst for the reduction of redox couple electrolyte exhibited a higher power conversion efficiency (PCE) of 7.01% than the Pt based device (6.77%) under one-sun illumination. We believe that the composites of CoSe₂ with RGO are a promising alternative material to the rare metal Pt catalyst in a CE of DSSCs.
