Recent Results From BESII

Rong-Gang Ping (for the BES Collaboration)
Institute of High Energy Physics,
Chinese Academy of Sciences,
P.O. Box 918-1, Beijing 100049, China

We present recent results from the BES experiment on the observation of the Y(2175) in J/ψ → φf₀(980)η, and η(2225) in J/ψ → γφφ, and X(1440) in J/ψ hadronic decays, together with the new observation of ψ(2S) radiative decays and hadronic decays into nK_L^0Λ + c.c., ΛΛη, Λ̄Λη. The effort to search for J/ψ decays into γγ and invisible decays are also reported.

I. INTRODUCTION

The analyses reported in this talk were performed using either a sample of 58 × 10^6 J/ψ events or a sample of 14 × 10^6 ψ(2S) events collected with the upgraded Beijing Spectrometer (BESII) detector at the Beijing Electron-Positron Collider (BEPC).

II. LIGHT HADRON SPECTROSCOPY

A. The Y(2175) in J/ψ → φf₀(980)η

A new structure, denoted as Y(2175) and with mass m = 2.175 ± 0.010 ± 0.015 GeV/c² and width Γ = 58 ± 16 ± 20 MeV/c², was observed by the BaBar experiment in the e⁺e⁻ → γISRφf₀(980) initial-state radiation process. This observation stimulated some theoretical speculation that this J^{PC} = 1^{−−} state may be an s-quark version of the Y(4260) since both of them are produced in e⁺e⁻ annihilation and exhibit similar decay patterns.

Here we report the observation of the Y(2175) in the decays of J/ψ → ηφf₀(980), with η → γγ, φ → K⁺K⁻, f₀(980) → π⁺π⁻. A four-constraint energy-momentum conservation kinematic fit is performed to the K⁺K⁻π⁺π⁻γγ hypothesis for the selected four charged tracks and two photons. η → γγ candidates are defined as γ-pairs with |M_{γγ} − 0.547| < 0.037 GeV/c², a φ signal is defined as |m_{K⁺K⁻} − 1.02| < 0.019 GeV/c², and in the π⁺π⁻ invariant mass spectrum, candidate f₀(980) mesons are defined by |m_{π⁺π⁻} − 0.980| < 0.060 GeV/c². The φf₀(980) invariant mass spectrum for the selected events is shown in Fig. 1 where a clear enhancement is seen around 2.18 GeV/c². Fit with a Breit-Wigner and a polynomial background yields 52 ± 12 signal events and the statistical significance is found to be 5.5σ for the signal. The mass of the structure is determined to be M = 2.186 ± 0.010 (stat) ± 0.006 (syst) GeV/c², the width is Γ = 0.065 ± 0.023 (stat) ± 0.017 (syst) GeV/c², and the product branching ratio is B(Y(2175) → φf₀(980)) · B(Y(2175) → φf₀(980)) · B(f₀(980) → π⁺π⁻) = (3.23 ± 0.75 (stat) ± 0.73 (syst)) × 10⁻⁴. The mass and width are consistent with BaBar’s results.

B. The η(2225) in J/ψ → γφφ

Structures in the φφ invariant-mass spectrum have been observed by several experiments both in the reaction π⁺p → φφn and in radiative J/ψ decays. The η(2225) was first observed by the MARK-III collaboration in J/ψ radiative decays J/ψ → γφφ. A fit to the φφ invariant-mass spectrum gave a mass of 2.22 GeV/c² and a width of 150 MeV/c². An angular analysis of the structure found it to be consistent with a 0⁺ assignment. It was subsequently observed by the DM2 collaboration, also in J/ψ → γφφ decays. We present results from a high statistics study of J/ψ → γφφ in the γK⁺K⁻K_L^0K_L^0 final state, with the K_L^0 missing and reconstructed with a one-constraint kinematic fit. After kinematic fit, we require both the K⁺K⁻ and K_L^0K_L^0 invariant masses lie within the φ mass region (|M(K⁺K⁻) − m_φ| < 12.5 MeV/c² and |M(K_L^0K_L^0) − m_φ| < 25 MeV/c²). The φφ invariant mass distribution is shown in Fig. 2. There are a to-
A partial wave analysis of the events with $M(\phi\phi) < 2.7$ GeV/c$^2$ was performed. The two-body decay amplitudes in the sequential decay process $J/\psi \rightarrow \gamma X, X \rightarrow \phi\phi, \phi \rightarrow K^+K^-$ and $\phi \rightarrow K_S^0K^+_L$ are constructed using the covariant helicity coupling amplitude method. The intermediate resonance $X$ is described with the normal Breit-Wigner propagator $BW = 1/(M^2 - s - iMT)$, where $s$ is the $\phi\phi$ invariant mass and $M$ and $\Gamma$ are the resonance’s mass and width. When $J/\psi \rightarrow \gamma X, X \rightarrow \phi\phi$ is fitted with both the $\phi\phi$ and $\gamma X$ systems in a $P$-wave, which corresponds to a pseudoscalar $X$ state, the fit gives 196±19 events with mass $M = 2.24^{+0.03+0.03}_{-0.02-0.02}$ GeV/c$^2$, width $\Gamma = 0.19 \pm 0.03 \pm 0.06$ GeV/c$^2$, and a statistical significance larger than 10$\sigma$, and a product branching fraction of $B(J/\psi \rightarrow \gamma\eta(2225)) \cdot B(\eta(2225) \rightarrow \phi\phi) = (4.4 \pm 0.4 \pm 0.8) \times 10^{-4}$. The presence of a signal around 2.24 GeV/c$^2$ and its pseudoscalar character are confirmed, and the mass, width, and branching fraction are in good agreement with previous experiments.

C. The $X(1440)$ in $J/\psi$ hadronic decays

A pseudoscalar gluonium candidate, the so-called $E_1(1440)$, was observed in $p\bar{p}$ annihilation in 1967 [13] and in $J/\psi$ radiative decays in the 1980’s [14-16]. The study of the decays $J/\psi \rightarrow \{\omega, \phi\}KK\pi$ is a useful tool in the investigation of quark and possible gluonium content of the states around 1.44 GeV/c$^2$. Here we investigate the possible structure in the $KK\pi$ final state in $J/\psi$ hadronic decays at around 1.44 GeV/c$^2$.

In this analysis, $\omega$ mesons are observed in the $\omega \rightarrow \pi^+\pi^-\pi^0$ decay, $\phi$ mesons in the $\phi \rightarrow K^+K^-$ decay, and other mesons are detected in the decays: $K_0^0 \rightarrow \pi^+\pi^-, \pi^0 \rightarrow \gamma\gamma$. $KK\pi$ could be $K_S^0K^+\pi^0$ or $K^+K^-\pi^0$.

Figures 3 and 4 show the $K_S^0K^+\pi^0$ and $K^+K^-\pi^0$ invariant mass distribution in $J/\psi \rightarrow \omega K_S^0K^+\pi^0$ (Fig. 3b) is fitted with a BW function convoluted with a Gaussian mass resolution function $(\sigma = 7.44$ MeV/c$^2$) to represent the $X(1440)$ signal and a third-order polynomial background function. The mass and width obtained from the fit are $M = 1437.6 \pm 3.2$ MeV/c$^2$ and $\Gamma = 48.9 \pm 9.0$ MeV/c$^2$, and the fit yields 249±35 events. Using the efficiency of 1.45% determined from a uniform phase space MC simulation, we obtain the branching fraction to be $B(J/\psi \rightarrow \omega X(1440)) = (4.86 \pm 0.69 \pm 0.81) \times 10^{-4}$, where the first error is statistical and the second is systematic.

For $J/\psi \rightarrow \omega K^+K^-\pi^0$ mode, by fitting the $K^+K^-\pi^0$ mass spectrum in Figure 3c with same functions, we obtain the mass and width of $M = 1445.9 \pm 5.7$ GeV/c$^2$ and $\Gamma = 34.2 \pm 18.5$ MeV/c$^2$, and the number of events from the fit is 62±18. The efficiency is determined to be 0.64% from a phase space MC simulation, and the branching fraction is $B(J/\psi \rightarrow \omega X(1440)) = (1.92 \pm 0.57 \pm 0.38) \times 10^{-4}$ in good agreement with the isospin symmetry expectation from $J/\psi \rightarrow \omega K_S^0K^+\pi^0$ mode.

The distribution of $K_S^0K^+\pi^0$ and $K^+K^-\pi^0$ invariant mass spectra recoiling against the $\phi$ signal are shown in Fig. 4 and there is no evidence for $X(1440)$. The upper limits on the branching fractions at the 90% C.L. are $B(J/\psi \rightarrow \phi X(1440) \rightarrow \phi K_S^0K^+\pi^0 + c.c.) < 1.93 \times 10^{-5}$ and $B(J/\psi \rightarrow \phi X(1440) \rightarrow \phi K^+K^-\pi^0) < 1.71 \times 10^{-5}$.

In conclusion, the mass and width of the $X(1440)$ are measured, which are in agreement with previous measurements; the branching fractions we measured are also in agreement with the DM2 and MARK-III results. The significant signal in $J/\psi \rightarrow \omega KK\pi$ mode and the missing signal in $J/\psi \rightarrow \phi X$ mode may indicate the $s\bar{s}$ component in the $X(1440)$ is not significant.
III. NEW OBSERVATIONS IN $J/\psi$ AND $\psi(2S)$ DECAYS

A. $\psi(2S)$ radiative decays

Besides conventional meson and baryon states, QCD also predicts a rich spectrum of glueballs, hybrids, and multi-quark states in the 1.0 to 2.5 GeV/$c^2$ mass region. Therefore, searches for the evidence of these exotic states play an important role in testing QCD. The radiative decays of $\psi(2S)$ to hadrons are expected to contribute about 1% to the total $\psi(2S)$ decay width \[18\]. However, the measured channels only sum up to about 0.05% \[18\].

We measured the decays of $\psi(2S)$ into $\gamma\rho\bar{\rho}$, $\gamma 2(\pi^+\pi^-)$, $\gamma K_S^0 K^+\pi^-$ + c.c., $\gamma K^+ K^-\pi^+\pi^-$, $\gamma K^{*0} K^-\pi^+ + c.c.$, $\gamma K^{*0} K^{*0}$, $\gamma \pi^+\pi^-\rho\bar{\rho}$, $\gamma 2 (K^+ K^-)$, $\gamma 3(\pi^+\pi^-)$, and $\gamma 2(\pi^+\pi^-) K^+ K^-$, with the invariant mass of the hadrons ($m_{hs}$) less than 2.9 GeV/$c^2$ for each decay mode \[19\]. The differential branching fractions are shown in Fig. 5. The branching fractions below $m_{hs} < 2.9$ GeV/$c^2$ are given in Table II which sum up to 0.26% of the total $\psi(2S)$ decay width. We also analyzed $\psi(2S) \rightarrow \gamma \pi^+\pi^-$ and $\gamma K^+ K^-$ modes to study the resonances in $\pi^+\pi^-$ and $K^+ K^-$ invariant mass spectrum. Significant signals for $f_2(1270)$ and $f_0(1710)$ were observed, but the low
FIG. 5: Differential branching fractions for \( \psi(2S) \rightarrow \gamma p \bar{p} \), \( \gamma(\pi^+\pi^-) \), \( \gamma K^+ K^- \pi^+ \pi^- \), and \( \gamma K^0_S K^+ K^- + c.c. \). Here \( m_{\psi(J/\psi)} \) is the invariant mass of the hadrons. For each point, the smaller longitudinal error is the statistical error, while the bigger one is the total error.

statistics prevent us from drawing solid conclusion on the other resonances [20].

B. \( J/\psi, \psi(2S) \rightarrow nK^0_S \Lambda + c.c., \Lambda \Lambda \pi^0, \Lambda \Lambda \eta \)

The \( X(2075) \) was first reported by BESII near the threshold of the invariant mass spectrum of \( p \Lambda \) in \( J/\psi \rightarrow p K^- \Lambda \) decays. The mass, width, and product branching fraction of this enhancement are \( M = 2075 \pm 12 \) (stat.) \( \pm 5 \) (syst.) MeV/\( c^2 \), \( \Gamma = 90 \pm 35 \) (stat.) \( \pm 9 \) (syst.) MeV/\( c^2 \) [21], and \( B(J/\psi \rightarrow K^- X) B(X \rightarrow p \Lambda + c.c.) = (5.9 \pm 1.4 \pm 2.0) \times 10^{-5} \) respectively. The study of the isospin conjugate channel \( J/\psi \rightarrow nK^0_S \Lambda \) is therefore important not only in exploring new decay modes of \( J/\psi \) but also in understanding the \( X(2075) \).

The invariant mass spectra of \( \Lambda K^0_S, nK^0_S, \) and \( \Lambda n(\Lambda \bar{n}) \), as well as the Dalitz plot for all selection requirements are shown in Fig. 6. In the \( \Lambda K^0_S \) invariant mass spectrum, an enhancement near \( \Lambda K^0_S \) threshold is evident, as is found in the \( \Lambda K \) mass spectrum in \( J/\psi \rightarrow p K^- \Lambda \) [22]. If the enhancement is fitted with an acceptance weighted S-wave Breit-Wigner function and a function \( f_{bg}(\delta) \) describing the phase space "background" contribution, the fit leads to \( M = 1.648 \pm 0.006 \) GeV/\( c^2 \) and \( \Gamma = 61 \pm 21 \) MeV/\( c^2 \), respectively. Here the errors are only statistical. The systematic uncertainties are not included since more accurate measurements of the mass and width should come from a full PWA involving interferences among \( N^* \) and \( \Lambda^* \) states. The fitted mass and width are consistent with those obtained from a partial wave analysis of \( J/\psi \rightarrow p K^- \Lambda \) [22]. The \( X(2075) \) signal which was seen in the \( p \Lambda \) invariant mass spectrum in \( J/\psi \rightarrow p K^- \Lambda \) is not significant here. Using a Bayesian approach [23] and fixing the mass and width of \( X(2075) \) to 2075 MeV/\( c^2 \) and 90 MeV/\( c^2 \) respectively, the upper limit on the number of events observed \( N^{UL} \) is 54 events at the 90% C.L.

The decay of \( J/\psi \) and \( \psi(2S) \) to \( nK^0_S \Lambda + c.c. \) are observed for the first time, and their branching fractions are:

\[
\begin{align*}
B(J/\psi \rightarrow nK^0_S \Lambda + c.c) &= (6.46 \pm 0.20 \pm 1.07) \times 10^{-4}, \\
B(J/\psi \rightarrow nK^0_S \Lambda) &= (3.09 \pm 0.14 \pm 0.58) \times 10^{-4}, \\
B(J/\psi \rightarrow nK^0_S \Lambda + c.c) &= (3.39 \pm 0.15 \pm 0.48) \times 10^{-4}, \\
B(\psi(2S) \rightarrow nK^0_S \Lambda + c.c) &= (0.81 \pm 0.11 \pm 0.14) \times 10^{-4}.
\end{align*}
\]

The isospin violating process \( J/\psi \rightarrow \Lambda \Lambda \pi^0 \) has been studied by DM2 [24] and BESI [25], and its average branching fraction is determined to be \( B(J/\psi \rightarrow \Lambda \Lambda \pi^0) = (2.2 \pm 0.6) \times 10^{-4} \) [26]. However, the isospin conserving process \( J/\psi \rightarrow \Lambda \Lambda \eta \) has not been reported, and there are no measurements for \( \Lambda \Lambda \pi^0 \) and \( \Lambda \Lambda \eta \) decays of \( \psi(2S) \).

Table I lists the results for \( J/\psi \) and \( \psi(2S) \) decay into \( \Lambda \Lambda \pi^0 \) and \( \Lambda \Lambda \eta \), as well as \( J/\psi \rightarrow \Sigma^+ \pi^- \Lambda + c.c. \). We also list the total branching fraction for the conjugate modes, where the common systematic errors have been taken out. Except for \( J/\psi \rightarrow \Lambda \Lambda \pi^0 \) and \( J/\psi \rightarrow \Sigma^+ \pi^- \Lambda + c.c. \), the results are first measure-

\begin{table}[h]
\centering
\begin{tabular}{|l|c|}
\hline
Mode & \( B \times 10^{-6} \) \\
\hline
\( \gamma p \bar{p} \) & 2.9 \pm 0.4 \pm 0.4 \\
\( \gamma(\pi^+\pi^-) \) & 39.6 \pm 2.8 \pm 5.0 \\
\( \gamma K^0_S K^+ \pi^- + c.c. \) & 25.6 \pm 3.6 \pm 3.6 \\
\( \gamma K^+ K^- \pi^+ \pi^- \) & 19.1 \pm 2.7 \pm 4.3 \\
\( \gamma K^0 S K^+ \pi^- + c.c. \) & 37.0 \pm 6.1 \pm 7.2 \\
\( \gamma K^0 S \bar{K}^0 \) & 24.0 \pm 4.5 \pm 5.0 \\
\( \gamma(\pi^+\pi^-) \) & 2.8 \pm 1.2 \pm 0.7 \\
\( \gamma K^+ K^- K^- \) & < 4 \\
\( \gamma(\pi^+\pi^-) \) & < 17 \\
\( \gamma(\pi^+\pi^-) \) & < 22 \\
\hline
\end{tabular}
\caption{Branching fractions for \( \psi(2S) \rightarrow \gamma + \text{hadrons} \) with \( m_{b\bar{b}} < 2.9 \) GeV/\( c^2 \), where the upper limits are determined at the 90% C.L.}
\end{table}
ments. Interestingly, the result of $J/\psi \to \Lambda \Lambda \pi^0$ presented here is much smaller than those of DM2 and BESI [24, 25]. In previous experiments, the large contaminations from $J/\psi \to \Sigma^0 \pi^0 \Lambda + \text{c.c.}$ and $J/\psi \to \Sigma^+ \pi^- \Lambda + \text{c.c.}$ were not considered, resulting in a large value of branching fraction for $J/\psi \to \Lambda \Lambda \pi^0$. The small branching fraction of $J/\psi \to \Lambda \Lambda \pi^0$ and relatively large branching fraction of $J/\psi \to \Lambda \Lambda \eta$ measured here indicate that the isospin violating decay in $J/\psi$ decays is suppressed while isospin conserving decays are favored, which is consistent with expectation.

IV. SEARCH FOR J/ψ RARE DECAYS VIA $\psi(2S) \to \pi^+ \pi^- J/\psi$

Search for $J/\psi$ rare decays, e.g. C-parity violation or invisible decays, suffers from removing the QED backgrounds from the direct annihilation of $e^+e^-$. Using the $J/\psi$ sample produced from $\psi(2S) \to \pi^+ \pi^- J/\psi$, the QED background can be strongly suppressed. The direct decay $J/\psi \to \gamma \gamma$ was previously measured to be $Br(J/\psi \to \gamma \gamma) < 5 \times 10^{-4}$. BES studies the decay $J/\psi \to \gamma \gamma$ using $J/\psi \to \pi^+ \pi^- J/\psi$, and the upper limit for the branching ratio is measured to be $Br(J/\psi \to \gamma \gamma) < 2.2 \times 10^{-3}$ at 90% confidence level, which is about 20 times lower than previous measurements.

Invisible decays of quarkonium states offer a window into what may lie beyond the standard model. In standard model (SM), the predicted branching fraction for $J/\psi \to \nu \bar{\nu}$ is $Br(J/\psi \to \nu \bar{\nu}) = 4.54 \times 10^{-7} \times \frac{\Gamma(J/\psi \to \gamma \gamma) + \Gamma(J/\psi \to e^+e^-)}{\Gamma(J/\psi \to e^+e^-)}$ with a small uncertainty (2%-3%). However, new physics beyond the SM might enhance the branching fraction of $J/\psi$ invisible decays. One possibility is the decay into light dark matter particles mediated by a new, electrically neutral spin-1 gauge boson $U$, which could significantly increase the invisible decay rate [27]. It is of interest to search for such light invisible particle in collider experiments. Using $\psi(2S) \to \pi^+ \pi^- J/\psi$ decays, a search for the decay of the $J/\psi$ to invisible final states is performed. The $J/\psi$ peak in the distribution of masses recoiling against the $\pi^+ \pi^-$ is used to tag $J/\psi$ invisible decays. No signal is found, and an upper limit at the 90% confidence level is determined to be $1.2 \times 10^{-2}$ for the ratio $\frac{Br(J/\psi \to \text{invisible})}{Br(J/\psi \to \mu^+ \mu^-)}$. This is the first search for $J/\psi$ decays to invisible final states.

V. SUMMARY

Using the 58 M $J/\psi$ and 14 M $\psi(2S)$ event samples taken with the BESII detector at the BEPC storage ring, BES experiment provided many interesting results in charmonium decays, including the observation of the $Y(2175)$, $\eta(2225)$, $X(1440)$, and many $\psi(2S)$ radiative decays. The effort to search for rare decays, e.g. $J/\psi$ decays into $\gamma \gamma$ and invisible decays are also reported. These results shed light on the understanding of role played by strong interactions in charmonium decays.
