Abstract

We study a new mechanism for the electromagnetic gauging of chiral bosons showing that new possibilities emerge for the interacting theory of chiral scalars. We introduce a chirally coupled gauge field necessary to mod out the degree of freedom that obstructs gauge invariance in a system of two opposite chiral bosons soldering them together. 1. Introduction. In the last few years there has been a great amount of investigation on the proper way to gauge 2D self-dual fields [1-7] and its d-dimensional extension [8, 9]. Despite of the successes of these indirect gauging schemes for the Floreanini-Jackiw (FJ) model, the results reported in [2] show clearly that the explicitly covariant model for chiral bosons put forward by Siegel [1] also suffer from the same difficulties regarding the coupling to gauge fields. In this work we show how the results already reported in the literature can be obtained directly from first principles using the compatibility between field equations and chiral constraints as guiding rule. We also show that, once this rule is relaxed, new and interesting possibilities emerge. These new gauging rules are the main result of this paper.

In Section 2 we show the incompatibility between the gauge invariant constraint and the field equations. In Section 3 we introduce a gauge field, chirally coupled to the chiral matter, which is necessary in order to sold [10] together a right and a left chiral boson. Our main result is presented in Section 4 where we use the dual projection scheme, proposed in [11, 12], to study new gauging schemes. Final discussions and perspectives are described in section 5.

2. The gauging procedure. In the literature about this subject, the basic difficulty in the chiral boson gauging is pointed to be the loss of Lorentz covariance which refrain us from using the minimal substitution scheme. It is in fact easy to see that there is an incompatibility between the chiral constraint and the matter field equation. For instance, the action for a flat space-time free scalar field in the light-front coordinates (our notation: $x^\pm = \frac{1}{\sqrt{2}}(x^0 \pm x^1)$ ; $\epsilon^{+-} = \epsilon^{-+} = 1$) is $\mathcal{L} = \partial_+ \phi \partial_- \phi$. The chiral constraint $\partial_- \phi \approx 0$ is consistent with the equations of motion (EM) before gauging, but not after. Indeed, suppose we gauge the system through the chiral derivative substitution rule: $\partial_+ \phi \longrightarrow \partial_+ \phi$ and $\partial_- \phi \longrightarrow D_- \phi$ where $D_\pm \phi = \partial_\pm \phi + A_\pm$. The EM for the scalar field now reads $\partial_+ D_- \phi \sim E$ with $E$ being the electric field on the line. Notice that the imposition of the gauge invariant constraint ($D_- \phi \approx 0$) becomes inconsistent with the field equation due to the appearance of the gauge anomaly. Suppose that the equations of motion for some general chiral theory reads, before gauging, $L \partial_- \phi = 0$, with $L$ being the differential
operator convenient for the Euler-Lagrange matter equation. If the gauging procedure chosen is, for instance, the direct substitution of partial derivatives by their covariant counterparts, the outcome after gauging will read $L D_- \phi \sim E$ displaying the above mentioned inconsistency. For chiral bosons, the question one may ask is if there exists any gauging procedure in which the chiral constraint remains compatible both before and after turning on the interactions. As a matter of fact, by examining the Lagrangian density proposed in \cite{6, 7}; $L = \partial_+ \phi \partial_- \phi - \partial_- \phi \partial_- \phi + 2e (\partial_+ \phi - \partial_- \phi)A_+ + \text{Gauge Terms};$ we get as the EM for the matter field, $\partial_1 D^e_- \phi = 0$, (where $D^e_\pm \phi = \partial_\pm + e A_\pm$) and this equation shows that the imposition of gauge invariant chiral constraint is not obstructed by the gauge anomaly. To obtain this result from first principles we need to find out what is the direct gauging scheme leading to this action. This we do next using the iterative Noether approach. To keep the most generality in the formulation of the problem, we consider the case of a scalar field minimally coupled to a background gravitational field.

The action for the standard minimal coupling of a scalar field to a metric $g_{\mu \nu}$ is

$$L_0 = \frac{1}{2} \sqrt{-g} g^{\mu \nu} \partial_\mu \phi \partial_\nu \phi.$$  

(1)

A convenient parametrization of the metric is given by (observe that it does not correspond to a partial gauge-fixing but it is consequence of the Weyl symmetry)

$$\frac{1}{2} \sqrt{-g} g^{\mu \nu} = \lambda \begin{pmatrix} 2 \lambda_- & 1 + \lambda_+ \lambda_- \\ 1 + \lambda_+ \lambda_- & 2 \lambda_+ \end{pmatrix}.$$  

(2)

where $\lambda = (1 - \lambda_+ \lambda_-)^{-1}$. For definiteness, from now on, let us consider the case of left chiral models. The (left) FJ and Siegel models can be obtained simply by truncation of this metric as $\lambda_- = 0$ for Siegel, and $\lambda_- = 0, \lambda_+ = -1$ for FJ, and this will be called as the chiral limit. By computing the EM for the $\phi$ field we observe that (before gauging) the chiral constraint cannot be imposed compatibly for arbitrary metric’s components, differently from what happens in the flat space-time case. However, if we restrict ourselves to the (left) chiral model limit above, where $\lambda_- = 0$, then we have compatibility for the free theory ($L \partial_- \phi = 0$ above) with the chiral constraint $\partial_- \phi = 0$. This is easily seen if we examine more closely the EM of (1) before gauging, $0 =$
\partial_+ \{ \lambda [ 2 \lambda_- \partial_+ \phi + (1 + \lambda_+ \lambda_-) \partial_- \phi ] + \partial_- \{ \lambda [ 2 \lambda_+ \partial_- \phi + (1 + \lambda_+ \lambda_-) \partial_+ \phi ] \} \}. The chiral constraint is not compatible with the EM. However, restriction to the chiral limit gives
\[ 0 = (\partial_+ + \partial_- \lambda_+ + \lambda_+ \partial_-) \partial_+ \phi \] for Siegel’s EM and \[ 0 = (\partial_+ - \partial_-) \partial_- \phi \] for FJ’s EM, which shows compatibility with \( \partial_- \phi \approx 0 \). After the Noether gauging with (left) chiral currents (see below), the result is \[ 0 = (\partial_+ + \partial_- \lambda_+ + \lambda_+ \partial_-) D_- \phi \] for Siegel’s EM and \[ 0 = (\partial_+ - \partial_-) D_- \phi \] for FJ’s EM. We see that for (left) chiral couplings, the gauge invariant constraint can be imposed over the field equations without being obstructed by the gauge anomaly. This is the only consistent possibility for the (left) chiral boson.

To implement the Noether procedure we need to compute the conserved currents associated to the global symmetries of the model. The axial current for (3) is \( J^+_{(A)} = \lambda [ 2 \lambda_- \partial_+ \phi + (1 + \lambda_+ \lambda_-) \partial_- \phi ] \) and \( J^-_{(A)} = \lambda [ 2 \lambda_+ \partial_- \phi + (1 + \lambda_+ \lambda_-) \partial_+ \phi ] \). Defining the vector current as dual to the axial current is not really a restriction of our method since this is a feature of the two dimensions. In any case, one can show that in the non-Abelian case, where the vector current can be defined as a Noether current, everything works as discussed here. Hence, the vector current is defined as dual to the axial one \( J^\mu_{(V)} = * J^\mu_{(A)} \) where the usual Hodge transformation must be generalized to \( * J^\mu_{(A)} = \sqrt{-g} g^{\mu \nu} \epsilon_{\nu \lambda} J^\lambda_{(A)} \) in order to take into account the presence of the gravitational background. A simple calculation shows that \( J^+_{(V)} = -\partial_- \phi \) and \( J^-_{(V)} = \partial_+ \phi \) are topologically conserved, as it should. Observe that the vector current is metric independent, being the same for the chiral models defined by truncation of the metric.

Having the axial and vectorial currents in hand, we are now in position to compute the right and left chiral currents. We find, \( J^+_{(L)} = 2 \lambda_- \lambda (\lambda_+ \partial_- \phi + \partial_+ \phi) \) and \( J^-_{(L)} = 2 \lambda_- \lambda (\lambda_+ \partial_- \phi + \partial_+ \phi) \) for the left current, and \( J^+_{(R)} = 2 \lambda_- \lambda (\lambda_- \partial_+ \phi + \partial_- \phi) \) and \( J^-_{(R)} = 2 \lambda_- \lambda (\lambda_- \partial_+ \phi + \partial_- \phi) \) for the right current. Observe that the (left) chiral boson limit \( (\lambda_- = 0) \) kills the \( J^+_{(L)} \) component, leaving the left current holomorphically conserved, while the right chiral current has both components non-vanishing. This is certainly a desired result for the chiral case. In fact, in the flat space-time theory for the free scalar field, there are two separated affine invariances for the left and right chiral sectors. These symmetries are reflected by the fact that both the right and left chiral
currents have only one non-zero component, \( J_{(L)}^- = J_{(L)}^-(x^+) \) and \( J_{(R)}^+ = J_{(R)}^+(x^-) \), since \( \partial_- J_{(L)}^- = 0 \) and \( \partial_+ J_{(R)}^+ = 0 \) and generate two commuting affine algebras. However, in the chiral case, only one of these currents keeps this property, i.e., either \( J_{(L)}^- = J_{(L)}^-(x^+) \) but \( J_{(R)}^+ \neq J_{(R)}^+(x^-) \) or \( J_{(L)}^- \neq J_{(L)}^-(x^+) \) but \( J_{(R)}^+ = J_{(R)}^+(x^-) \). This can also be seen from the fact that, for chiral theories, while the vector and axial transformations are global symmetries, the affine transformations are semi-local symmetries. Take for instance the case of a left Siegel boson. The semi-local shift \( \phi \rightarrow \phi + \alpha(x^+) \) certainly leaves the action invariant, but \( \phi \rightarrow \phi + \alpha(x^-) \) does not. The Noether current is immediately identified as \( J^- = 2(\partial_+ \phi + \lambda_+ \partial_- \phi) \) and \( J^+ = 0 \) which is easily seen to be the (left) chiral limit of \( J_{(L)}^+ \) and \( J_{(L)}^- \) above.

We shall examine next the coupling of all these four currents with an external electromagnetic field. We do this iteratively, introducing the necessary Noether counter-terms. Let us first examine the coupling with the vector current \( J_{(V)}^+ \) and \( J_{(V)}^- \) in the standard way: \( \mathcal{L}_0 \rightarrow \mathcal{L}_1 = \mathcal{L}_0 + A_+ J_{(V)}^+ + A_- J_{(V)}^- \), where \( \mathcal{L}_0 \) is defined by Eq. (1). The global vector symmetry present in \( \mathcal{L}_0 \) has been lift to a local symmetry in \( \mathcal{L}_1 \). We observe that, after gauging, the vector current remains conserved, but the axial current does not. A direct calculation shows that \( \partial^\mu J^\mu_{(A)} = \partial_- A_+ - \partial_+ A_- = E \) which, again, being independent of the metric elements, is valid for all cases. By computing the EM for \( \mathcal{L}_1 \) we clearly see that the original compatibility between constraint and EM has been destroyed for the gauging with vector currents \( J_{(V)}^+ \) and \( J_{(V)}^- \) due to the presence of the anomaly. Therefore, we have to rule out the vector current gauging as inappropriate for chiral theories.

Let us consider next the case of axial coupling. The free action changes to \( \mathcal{L}_0 \rightarrow \mathcal{L}_1 = \mathcal{L}_0 + A_+ J_{(A)}^+ + A_- J_{(A)}^- \). Differently from the vector case, under an axial transformation the action \( \mathcal{L}_1 \) does not remain invariant but its variation is given by \( \delta \mathcal{L}_1 = -\delta\{\lambda [-\lambda_- A_+^2 + \lambda_+ A_-^2 + 1 + \lambda_+ \lambda_- A_+ A_-] \} \). A further modification of the action as

\[
\mathcal{L}_1 \rightarrow \mathcal{L}_2 = \mathcal{L}_1 + \frac{1}{1 - \lambda_+ \lambda_-} \left[ \lambda_- A_+^2 + \lambda_+ A_-^2 + (1 + \lambda_+ \lambda_-) A_+ A_- \right]
\] (3)

leaves the action \( \mathcal{L}_2 \) invariant under an axial transformation. It is simple to check that here, the axial current remains conserved, while the gauge coupling modifies the vector
current, which now fails to be conserved. Finally, by checking the EM, one notices the incompatibility of the gauged constraint with the field equation, which also rules out this coupling as inappropriate for the chiral models.

We are then left only with the possibilities of chiral current couplings. We have explicitly checked that for left chiral bosons, the coupling with the right chiral current results incompatible. Now, let us work out explicitly the coupling of the left chiral current and verify that this is the only possible consistent way of coupling. The Noether procedure then gives \( \mathcal{L}_0 \rightarrow \mathcal{L}_1 = \mathcal{L}_0 + A_+ J^+_L + A_- J^-_L \) whose variation reads

\[
\delta \mathcal{L}_1 = \lambda \left[ (2 \lambda_+ + \lambda_- A_+ \partial_- \alpha + 2 A_+ \partial_+ \alpha) - \delta (\lambda_- A^2_+ + \lambda_+ A^2_-) \right].
\]

The second term can be reabsorbed into a redefinition of the action as

\[
\mathcal{L}_1 \rightarrow \mathcal{L}_2 = \mathcal{L}_1 + \lambda_+ A^2_- + \lambda_- A^2_+,
\]

but the first piece cannot be eliminated by any choice of a Noether counter-term. This is true even for the truncated chiral limit but it is hardly a surprise since the gauged action for chiral models are not expected to be gauge invariant. However, this action has the nice property of having its variance independent of the matter fields.

The important point to observe is that the truncation process used to go from the non-chiral to the chiral case does not change the nature of the coupling, which means that the vector, axial and chiral couplings studied above remains the same after truncation. This is certainly different from the projection process using chiral constraints that transform, for instance, the vector coupling into a chiral coupling.

It must be pointed out that the FJ chiral limit of \( \mathcal{L}_2 \) in Eq. (4) is identical to that in Refs. [6, 7], obtained via left projection of the chiral Schwinger model (SM), but the other limits here are new results. In particular we emphasize that we did not invoke the chiral SM at any level, but derive our result from first principles.

Finally, we believe that for chiral bosons actions which use infinite auxiliary fields [8] (the equivalence between both proposals was demonstrated in Ref. [13]), the procedure is the same, but now we have a sum of infinite chiral currents, one for each field, that are embedded in an external electromagnetic field. Similarly, for the PST formulation [14] of
the Siegel chiral boson, it is not difficult to see that that procedure also works.

3. A gauging example. As a simple illustration of the use of the gauged theory, the property mentioned above is explored now in order to sold together two bosons of opposite chiralities. Details can be found in Ref. [10]. The soldering process is non trivial since the simple sum of the actions of a right and a left chiral boson is not equal to the action of a single scalar field.

For computational convenience we use front-form variables. In this coordinate system, the action for left and right FJ chiral bosons read, respectively

\[ L_0^{(\pm)} = \pm \dot{\phi}_\pm \phi'_\pm - (\phi'_{\pm})^2, \]

where dot and prime have their usual significance as time and space derivatives respectively. We know, from their field equations, that these models have a residual invariance under a semi-local transformation \( \phi_\pm \to \tilde{\phi}_\pm = \phi_\pm + \alpha_\pm(t) \). Therefore, if one defines a scalar field as a combination of these chiral ones as \( \Phi = \phi_+ - \phi_- \), then clearly the combination of the two semi-local transformations above will not lead to a vector transformation for the scalar field, unless some constraint is imposed over each individual component. This is the role played by the gauge field. We can then follow the gauging procedure described above to obtain the action of an interacting chiral boson coupled to a gauge field through their chiral left and right currents, respectively

\[ L_0^{(\pm)} \to L_1^{(\pm)} = L_0^{(\pm)} \mp 2A (\dot{\phi}_\pm \pm \phi'_{\pm}). \]

Here \( A \) is the space-component of the gauge field, i.e., \( A \) is the so-called soldering field, an auxiliary field that will be eliminated (integrated) through the field equations (or through the path integral, as below). Although each individual (gauged) action is variant under a gauge transformation, as we have seen in the last section, (see Eq. [4]) one can verify that the new action \( \mathcal{L} = \mathcal{L}_1^- + \mathcal{L}_1^+ - 2A^2 \) is indeed invariant. The last term is a contact term that compensates for the non-invariances of each chirality. Now, we can integrate out the gauge field \( A \), as \( e^{i \int d^2xW} = \int [dA] e^{i \int d^2xL} \) to obtain \( W = \frac{1}{2} \partial_\mu \Phi \partial^\mu \Phi \), which is the action for the scalar field \( \Phi = \phi_+ - \phi_- \) defined as a combination of a right and a left chiral boson.

4. The dual projection approach. In this section we consider another approach to the chiral gauge problem based on the dual projection [11, 12] of scalar fields. The basic idea in this scheme is to gauge the scalar theory, using the obvious covariance that
it possess, and then “break” the basic fields, in phase space, into its chiral components. For the definiteness, let us consider a well known generalized chiral SM (GCSM), \( \mathcal{L} = \Psi \gamma^\mu \left( i\partial_\mu + e_R A_\mu \frac{\gamma^A + \gamma^5}{2} + e_L A_\mu \frac{\gamma^A - \gamma^5}{2} \right) \Psi \) where \( \Psi \) is a two-component spinor \( \Psi = \begin{pmatrix} \psi_R \\ \psi_L \end{pmatrix} \), and \( \psi_L \) and \( \psi_R \) are the Weyl components. Its quantum dynamics is easily computed using the bosonized version after a convenient redefinition of the fields, \( \mathcal{L}_{Boson} = \frac{1}{2} \partial_\mu \phi \partial^\mu \phi - e^- A_\mu \partial^\mu \phi + e^+ A_\mu \epsilon^\mu \partial_\nu \phi + g^2 a^2 A_\mu A^\mu \) where \( e_R = \frac{1}{2} (e_+ + e_-) \), \( e_L = \frac{1}{2} (e_+ - e_-) \), \( g^2 = (e_-^2 + e_+^2)/2 \) and \( a \) is an arbitrary regularization parameter. The interesting point in working with the GCSM is that one can easily obtain the four versions of the SM considered in the literature: Vector SM \( (e_- = 0 \Rightarrow e_L = e_R = e) \); Axial SM \( (e_+ = 0 \Rightarrow e_L = -e_R = e) \); Right Chiral SM \( (e_L = 0 \Rightarrow e_+ = e_- = e) \) and Left Chiral SM \( (e_R = 0 \Rightarrow e_+ = -e_- = e) \). The dual projection scheme permits one to realize that the second-order differential EM for the matter field coming from action \( \mathcal{L}_{Boson} \) contains both right and left moving solutions. Let us reduce this action to its first-order form as,

\[
\mathcal{L} = \pi \dot{\phi} - \frac{1}{2} \pi^2 - \frac{1}{2} (\phi')^2 - (e_- A_0 + e_+ A_1) \pi + (e_- A_0 + e_+ A_0) \phi' + \frac{1}{2} A_\mu M^{\mu \nu} A_\nu \quad (5)
\]

where \( A_\mu M^{\mu \nu} A_\nu = ag^2 A_\mu A^\mu -(e_- A_0 + e_+ A_1)^2 \) and \( \pi \) is the second field mentioned above obtained through Legendre transformation from \( \mathcal{L}_{Boson} \). We observe that the fields \( \phi \) and \( \pi \) cannot be our chiral fields describing, independently, the right and left dynamics since they appeared coupled in the symplectic sector of Eq. (5). We must therefore look for a linear combination of them that diagonalize the action. If we introduce the new fields \( \varphi \) and \( \rho \) as an \( SO(2) \) rotation of the \( \pi \) and \( \phi \) fields as, \( \begin{pmatrix} \pi \\ \phi' \end{pmatrix} = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} \varphi' \\ \rho' \end{pmatrix} \)

then we quickly realize that, in order to diagonalize the action \( \mathcal{L} \), we must have \( \theta = \pi/4 \), and consequently the following canonical transformations (CT) \( \pi = \pi' - \rho' \) and \( \varphi = \varphi' - \rho' \), which we take as our definition of the chiral fields \( \varphi \) and \( \rho \). In terms of these new fields the action for the GCSM, \( \mathcal{L}_{Boson} \), now reads, \( \mathcal{L}_{Boson} = \mathcal{L}_\varphi + \mathcal{L}_\rho + \mathcal{L}_A \) where \( \mathcal{L}_\varphi = \dot{\varphi} \varphi' - \varphi'^2 + 2e_L \varphi' A_-; \mathcal{L}_\rho = -\dot{\rho} \rho' - \rho'^2 + 2e_R \rho' A_+ \) and \( \mathcal{L}_A = \frac{1}{2} A_\mu M^{\mu \nu} A_\nu \)

with \( A_\pm = A_0 \pm A_1 \).

There are many interesting points to observe in this now diagonalized action. Notice
that in the free case the chiral fields satisfy $\partial_- \phi = 0$ and $\partial_+ \rho = 0$ so that they are, respectively, left and right chiral modes. The action for the free components are those proposed by FJ. Also, no matter which model is in discussion, the interaction piece shows that these fields only couple to a proper chiral combination of the electromagnetic field, $A_-$ and $A_+$ respectively, but the coupling constant is, obviously, model dependent. For the vector and axial SMs both chiral components are coupled to the photon field but the chiral SM will leave one chirality free, either $\phi$ when $e_L = 0$ or $\rho$ when $e_R = 0$. In all these cases the mass term will change appropriately. What should be regarded as the most important point is that this dual projection shows the chiral bosons correctly coupled to the photon field as proposed by Refs. [6, 7]. However in our case we got the coupling of both chiralities at once. In the name of completeness, analysing the case of chiral bosons’s models with infinite auxiliary terms coupled to gravity, using the dual projection, it was shown [3] that this model has nonmovers fields, the notons (introduced by Hull [16] to cancel the Siegel anomaly), which couple naturally with the gravitational field. For the PST version of Siegel chiral boson, it was proved that its spectrum is composed by a FJ particle and a PST version of the noton [12].

We are now in position to compare this result with the chiral projection technique adopted in Ref. [7]. From the CT defined above we get $\pi - \phi' = -2\rho'$ and $\pi + \phi' = 2\phi$, so that the chiral constraints $\pi \pm \phi' = 0$ lead to $\phi = 0$ and $\rho = 0$ as constraints, respectively. It should be observed that the chiral component eliminated through this process need not be a free component, so that one does not need to start with a chiral SM in order to get the gauged chiral boson. So, except for some very awkward possibilities, any model will do. Finally, we must observe that the CT above leads to a very sensible interpretation of the chiral bosons $\phi$ and $\rho$ as being the bosonized components of the Weyl fermions in the GCSM since they are coupled to the gauge field with the same strength as their fermionic counterparts.

5. Final Discussions. In conclusion, in this work we have studied the problem of coupling self-dual scalar fields in $2D$ to an external electromagnetic field described by a vector potential $A_\mu$. We have recognized the basic difficulty as an incompatibility
between the gauge invariant chiral constraint and the field equation for the matter field. Using consistency as a guiding rule, we have worked out the coupling of gauge fields with different matter currents and, observed that the only consistent coupling for a left chiral matter is with a left chiral current. This explain the results obtained with the use of the chiral projector on the SM. As an application we verified that in order to sold together a left and a right chiral boson into a scalar field, we must (chirally) couple them to a gauge field that will mod out the degree of freedom that obstructs gauge invariance.
