Abstract

Proliferation and migration during adult neurogenesis are regulated by a microenvironment of signaling molecules originating from local vasculature, from CSF produced by the choroid plexus, and from local supporting cells including astrocytes. Here, we focus on the function of OTX2 homeoprotein transcription factor in the mouse adult ventricular-subventricular zone (V-SVZ), which generates olfactory bulb neurons. We find that OTX2 secreted by choroid plexus is transferred to the supporting cells of the V-SVZ and rostral migratory stream. Deletion of Otx2 in choroid plexus affects neuroblast migration and reduces the number of olfactory bulb newborn neurons. Adult neurogenesis was also decreased by expressing secreted single-chain antibodies to sequester OTX2 in the CSF, demonstrating the importance of non-cell-autonomous OTX2. We show that OTX2 activity modifies extracellular matrix components and signaling molecules produced by supporting astrocytes. Thus, we reveal a multilevel and non-cell-autonomous role of a homeoprotein and reinforce the choroid plexus and astrocytes as key niche compartments affecting adult neurogenesis.

Key words: astrocyte; CSF; extracellular matrix; homeoprotein

Introduction

Neurogenesis in the adult mouse brain provides continuous replacement of interneurons in olfactory bulbs (OBs) and is important for olfaction-based learning (Lledo and Valley, 2016). Neural stem cells (NSCs), located in the adult ventricular-subventricular zone (V-SVZ) lining the lateral cerebral ventricles, give rise to progenitor cells (the first transient amplifying cells that generate migrating neuroblasts) that migrate though the rostral migratory stream (RMS) to reach the OB where they differentiate as interneurons and integrate into local circuitry. This process is regulated not only by factors intrinsic to the NSCs and progenitors but also by their microenvironment consisting of factors from local vasculature, neuronal circuits, CSF, and local supporting cells (Lehtinen et al., 2013; Silva-Vargas et al., 2013; Bjornsson et al., 2015). It has been
shown that NSCs contact vascular endothelial cells and project into the ventricular wall where their cilia contact CSF, which participates in regulating proliferation and migration through mechanical influence and CSF-borne factors (Sawamoto et al., 2006; Mirzadeh et al., 2008; Shen et al., 2008; Petrik et al., 2018). The CSF is produced within brain ventricles by the choroid plexuses (ChPs), which express many secreted factors found to influence neurogenesis, including growth factors, morphogens, and guidance clues (Falcao et al., 2012; Kokovay et al., 2012; Silva-Vargas et al., 2016). Examples of CSF-borne factors include IGF2 (insulin-like growth factor 2), which promotes adult NSC renewal (Ziegler et al., 2015); IGF1 and BMP5 (bone morphogenetic protein 5), which promote NSC colonies (Silva-Vargas et al., 2016); NT-3 (neurotrophin-3), which promotes quiescence (Delgado et al., 2014); and SLIT2 (slit guidance ligand 2), a chemorepulsive factor that participates in neuroblast migration (Nguyen-Ba-Charvet et al., 2004; Sawamoto et al., 2006). Neuroblasts and NSCs also contact local non-neurogenic astrocytes (Lois et al., 1996; Shen et al., 2008), which secrete factors that help to establish and maintain the microenvironment and can influence neurogenesis (for review, see Gengtharan et al., 2016). Such factors include DLK1 (delta-like non-canonical notch ligand 1), which induces NSC self-renewal (Ferron et al., 2011), and thrombospondin 4 (THBS4), which guides neuroblast migration (Girard et al., 2014).

Homeoproteins are key regulators of neurogenesis both during embryogenesis and in the adult (Curto et al., 2014; Prochiantz and Di Nardo, 2015). This class of transcription factors has the property to act both cell autonomously and non-cell autonomously after secretion and internalization in target cells. The Otx2 homeoprotein is a regulator of embryonic development and embryonic neurogenesis (Yang et al., 2014; Hoch et al., 2015; Acampora et al., 2016), but its role in adult neurogenesis has not been investigated. OTX2 is expressed by ChP, secreted in CSF, and transfers in brain parenchyma to regulate cortical plasticity in postnatal mice (Spatzaza et al., 2013; Lee et al., 2017). We hypothesized that OTX2 in the CSF might also accumulate in adult neurogenic niches and impact neurogenesis. Indeed, we find that V-SVZ neurogenesis is regulated by OTX2 expression and secretion by the ChP, and find that OTX2 transfers into supporting astrocytes to control the expression of extracellular factors that impact neuroblast migration.

Materials and Methods

Animals

S129 mice were purchased from Charles River Laboratories. The Otx2lox/lox (Otx2-lox) mice (S129 background) were donated by Dr. T. Lamonier, Institut de Biologie Valrose, Nice, France (Fossat et al., 2006), and Otx21/1/GFP mice were donated by Dr. A. Simone, Institute of Genetics and Biophysics, Napoli, Italy (Acampora et al., 2009). The single-chain antibody (scFv) knock-in mouse model (scFv-Otx2 mice, C57BL/6J background) were previously described (Bernard et al., 2016). Adult mice (3 months old) of either sex were used in all experiments, with littermates distributed equally between control and treated groups while maintaining sex balance. All animal procedures, including housing, were conducted in accordance with the guidelines of the European Economic Community (2010/63/UE) and the French National Committee (2013/118). This research (project #00704.02) was approved by Ethics Committee 59 of the French Ministry for Research and Higher Education. Mice were conventionally raised (12 h light/dark cycle) in cages with red tunnels, nesting cotton, and food and water available ad libitum.

Mouse surgery

For surgical procedures, animals were anesthetized with xylazine (2% Rompun, Bayer; 5 mg/kg) and ketamine (Imalgene 500, Merial; 80 mg/kg). Cre-Tat recombinant protein (8-20 μg/ml in 400 mM NaCl, 15% DMSO) or vehicle was injected as previously described (Spatzaza et al., 2013). Ten days after Cre-Tat injection, mice were injected intraperitoneally with 150 mg/kg BrdU (B9285, Sigma-Aldrich; at 10 mg/ml diluted in NaCl 0.9%). For OB integration experiments, mice were injected with BrdU twice daily for 5 d, and then housed for 3 weeks before perfusion with PBS. For proliferation experiments, mice were injected with one pulse of BrdU and then perfused with PBS 2 h later. Brains were cut in half along the anterior–posterior axis: the anterior half was fixed for 48 h at 4°C in 4% formaldehyde-PBS, immersed overnight in 20% sucrose PBS, and processed for cryostat sectioning; the posterior half was used to recover fourth ventricle ChP for quantitative PCR analysis of Otx2 expression.

Astrocyte cell culture

Primary astrocytes were prepared from cortex of newborn mouse [postnatal day 0 (P0) to P4] of either sex and cultured in 10 ml of DMEM high glucose, 10% serum, 1× antimitotic/antibiotic (Méme et al., 2006). After 7 d, astrocytes were passaged into 6-well plates at 400,000 cells/ml, incubated for 14 d, and then treated with 1% Ara-C (in DMEM high glucose, 1% B27, 1× antimitotic/antibiotic) for 24 h before treatment with 100 ng/ml Otx2 protein. After 24 h, treated astrocytes were processed for quantitative PCR analysis.

Immunohistochemistry and histology

Frozen brains were sectioned (25 or 40 μm) by cryostat and stored at −20°C. For all staining experiments, slides were thawed for 15 min at room temperature, hydrated in PBS, and incubated for antigen retrieval in a steamer for March/April 2019, 6(2) e0262-18.2019
15 min with 10 mM citrate buffer, pH 6. After cooling, sections were washed with PBS and incubated in blocking buffer [0.5% Triton-X, 10% normal donkey serum (Abcam) in PBS] for 30 min. Primary antibodies were incubated overnight at room temperature [1/100 rat anti-BrdU OBT0030, AbD Serotec (RRID:AB_609568); 1/400 rabbit anti-caspase #9661, Cell Signaling Technology (RRID:AB_2341188); 1/250 rabbit anti-OTX2 ab92326 Abcam (RRID:AB_10562130); 1/1000 guinea pig anti-DCX (doublecortin) AB2253, Millipore (RRID:AB_1586992); 1/200 mouse anti-GFAP G6171, Sigma-Aldrich (RRID:AB_1840893); 1/1000 chicken anti-Vimentin AB5733, Milipore (RRID:AB_11212377); 1/1000 chicken anti-GFP ab13970, Abcam (RRID:AB_300798)]. After PBS washes, secondary antibodies (1/2000 donkey anti-IgG Alexa Fluor, Invitrogen; RRID:AB_142924, RRID:AB_2535794, RRID:AB_141637, RRID:AB_141607) were incubated for 2 h at room temperature. For DCX labeling, sections were washed with PBS, incubated for 2 h at room temperature with secondary antibody (1/500 biotinylated goat anti-guinea pig ab6907, Abcam; RRID:AB_954847), washed again with PBS, and incubated for 2 h with conjugated streptavidin (1/2000 Alexa Fluor Streptavidin, Invitrogen; RRID:AB_2336066). Sections were washed in PBS, dried, and mounted in DAPI Fluoromount-G (Southern Biotech). TUNEL was performed with the in situ cell death detection kit (11684817910 Roche) according to manufacturer instructions. In situ hybridization was performed as previously described (Spatazza et al., 2013).

Imaging and quantification

Imaging was performed with an SP5 inverted confocal microscope (Leica), a Nikon 90i upright wide-field microscope, or a Spinning-disk confocal microscope with constant parameters. For BrdU analysis, one 40 μm coronal section every 200 μm was quantified. BrdU counting in the granule cell layer (GCL) and glomerular layer (GL) from the same mice was performed on six sections per animal the granule cell layer (GCL) and glomerular layer (GL) from the same mice was performed on six sections per animal. BrdU counting, sections were washed with PBS, incubated for 2 h at room temperature with secondary antibody (1/500 biotinylated goat anti-guinea pig ab6907, Abcam; RRID:AB_954847), washed again with PBS, and incubated for 2 h with conjugated streptavidin (1/2000 Alexa Fluor Streptavidin, Invitrogen; RRID:AB_2336066). Sections were washed in PBS, dried, and mounted in DAPI Fluoromount-G (Southern Biotech). TUNEL was performed with the in situ cell death detection kit (11684817910 Roche) according to manufacturer instructions. In situ hybridization was performed as previously described (Spatazza et al., 2013).

Quantitative PCR

Total RNA from fourth ventricle ChP was extracted with the RNeasy Lipid Tissue Mini Kit (Qiagen) with DNA removal. RNA and protein were extracted for extracellular matrix (ECM) composition analysis using the AllPrep DNA/RNA/Protein Mini Kit (Qiagen). RNA processing was performed with the QuantiTect Reverse Transcription Kit (Qiagen). cDNA was diluted 1:10 with RNase-free water for quantitative PCR samples, which were analyzed in triplicate with a LightCycler 480 II (Roche) and SYBR Green I Master mix. After T_m profile validation, gene expression was determined by the 2^-ΔΔCt method with hypoxanthine guanine phosphoribosyl transferase as the control gene. For expression analysis, the mean expression of vehicle-injected mice or control-treated cells was used for comparison.

Microdissection

For biochemical analysis, mice were killed by cervical elongation. Brain was placed in cold PBS, dorsal side facing up, and two equidistant longitudinal incisions in each OB were made to divide them into three parts while keeping them attached to the rest of the brain. The V-SVZ microdissection was performed as previously described (Mirzadeh et al., 2010). Afterward, the hemispheres were placed once again dorsal side facing up and the two sagittal cuts starting from the OB incisions were pursued along the entire length of the brain. The central piece of tissue was laid on its side, and RMS was excised (see Fig. 2D). All tissue samples were stored at −80°C.

Immunoprecipitation and Western blot

Microdissections were triturated in 100 μl of lysis buffer [150 mM NaCl, 1% Triton X-100, 100 mM Tris, pH 7.4, 10 mM EDTA, 1× protease/phosphatase inhibitor (Roche)] per 10 mg of tissue and incubated 10 min on ice. Supernatant was recovered in low-bind tubes after centrifugation for 10 min at 16,000 × g. Antibody was added [2.5 μg of anti-OTX2 (ab21990, Abcam) or anti-IgG (ab27478, Abcam)] and incubated overnight at 4°C with rotation. Protein A Sepharose beads (GE Healthcare) were washed twice and resuspended 1:1 with lysis buffer. Beads (30 μl) were added to each sample and incubated 3 h at 4°C. Beads were recovered by centrifugation for 1 min at 16,000 × g and washed five times with 1 ml of cold wash buffer (Lysis buffer with 500 mM NaCl). Proteins were eluted from the beads with 30 μl of 2× Laemmli buffer, heated for 5 min at 95°C, and stored at −20°C.

Samples were separated on NuPage 4–12% Bis-Tris precast gels (Invitrogen) with 1× MES buffer and antioxidant (Invitrogen) then processed for Western blotting for OTX2 detection. Membranes were blocked in 5% nonfat milk, TBS, 0.2% Tween, incubated with anti-OTX2 (in-house mouse monoclonal) overnight at 4°C then incubated with HRP-conjugated anti-mouse (GeneTex) for 2 h at room temperature. A chemiluminescence reaction was performed with ECL Femto (Thermo Fisher Scientific). These immunoprecipitation experiments were performed three times, with similar results each time.

Statistical analysis

Prism 8 software (GraphPad Software) was used for all statistical analyses. Sample size was determined after preliminary experiments. Quantification was normalized by the mean value of vehicle-injected mouse samples. Normal data distribution was assessed by the D’Agostino and Pearson omnibus normality test. If a normal test was not passed, the Mann–Whitney test was applied; otherwise, an unpaired t test with Welch’s correction was used (note t test in figure legends). See figure legends for relevant statistical tests, and see Table 1 for results.
Otx2 knockdown in choroid plexus reduces newborn neurons in the olfactory bulb

Intracerebroventricular injections of vectorized Cre recombinase (Cre-Tat) leads to specific recombination of Otx2 in lateral ventricle ChP of Otx2-lox mice (Spatazza et al., 2013). With this paradigm, we find that Cre-Tat intracerebroventricular injection leads to a strong decrease in OTX2 protein in lateral ventricle ChP compared with vehicle-injected mice (Fig. 1A) and also a decrease in Otx2 mRNA expression in both lateral and fourth ventricle ChP (Fig. 1B). While the decrease is not necessarily proportional between both ChPs for a given mouse, when a decrease of >30% was observed in one ChP, a decrease of at least 30% was observed in the other ChP (Fig. 1B). Therefore, the fourth ventricle ChP quantitative PCR analysis is a valid method to assess Otx2 expression levels in lateral ChP so that anterior tissues can be used for histologic quantification. Otx2-lox mice with <30% Otx2 expression knockdown in the fourth ventricle after Cre-Tat intracerebroventricular injection where excluded from subsequent analysis. For the experiments described below, Cre-Tat injections in lateral cerebral ventricles lead to 60% decrease in Otx2 mRNA expression on average in the fourth ventricle ChP (Fig. 1C).

To assess whether Otx2 knockdown in ChP alters V-SVZ neurogenesis, we used BrdU treatments to measure either newborn neuron integration in OB (3 weeks postinjection; Fig. 1D–F) or cell proliferation in V-SVZ (2 h postinjection; Fig. 1I–K) after Cre-Tat or vehicle intracerebroventricular injections. We found a significant decrease in the density of GCL newborn neurons but no change in the density of GL newborn neurons after Otx2 knockdown (Fig. 1F). This change in density was not due to gross

structural changes as no significant change in OB area was observed (Table 1, GCL+GL area) and was not dependent on sex (Table 1). Analysis of caspase-expressing cells revealed no change in cell death in the RMS of Cre-Tat-injected mice (Fig. 1G,H), suggesting that OTX2 does not affect neuroblast survival. However, OTX2 knockdown in ChP does not alter V-SVZ cell proliferation (Fig. 1K), suggesting that the observed decrease in newborn neurons is due to effects on neuroblast migration. To test this hypothesis, we used a migration paradigm in which we evaluated the density of BrdU/DCX colabeled cells in the RMS 6 d after final BrdU injection (Fig. 1L–N). We observed a significant decrease in Cre-Tat-injected animals, suggesting that fewer neuroblasts are leaving the V-SVZ and/or that they are migrating slower (Fig. 1N).

Non-cell-autonomous Otx2 in V-SVZ and RMS

Given that OTX2 is secreted from ChP into the CSF and accumulates in brain parenchyma (Spatazza et al., 2013), we hypothesized that OTX2 transfers from ChP to the V-SVZ niche. The Otx2 locus is silent in V-SVZ and RMS, as shown by the absence of GFP expression in Otx2^{+/GFP} mice (Fig. 2A,B) and by Otx2 in situ hybridization (Fig. 2C). However, OTX2 protein is immunoprecipitated from lysates of V-SVZ and RMS microdissections (Fig. 2D) but not from striatum lysates (microdissection beneath V-SVZ); lysates of superior colliculus, in which Otx2 locus is active, were used as positive controls (Fig. 2E). Immunostaining showed the selective presence of OTX2 in a subset of cells within the V-SVZ and RMS (Fig. 3), suggesting that it could be targeting either neural stem cells or progenitor cells directly and/or other cells
within the niche. OTX2 is not internalized in neuroblasts (DCX+ cells) in V-SVZ but accumulates in a small number of GFAP-labeled cells and many ependymal cells (Fig. 3A,B). In and around the RMS, OTX2 is again absent in neuroblasts yet is in many GFAP-labeled cells (Fig. 3C,D).

OTX2 protein in regions of neuroblast proliferation and migration suggests that reduced newborn neurons in OB after Otx2 ChP knockdown in Otx2-lox mice (Fig. 1F) could be due in part to OTX2 non-cell-autonomous activity. To test this hypothesis, we used the scFv-Otx2 mouse model, which conditionally expresses a single-chain antibody (scFv) that blocks transfer by sequestering OTX2 in the CSF (Bernard et al., 2016). Cre-Tat intracerebroventricular injection leads to local scFv-Otx2 expression by ChP cells (GFP reporter; Fig. 4A) and secretion into the CSF, which can lead to ~20% decrease in cortical OTX2 levels after 2 weeks (Bernard et al., 2016). Here, 35 d after Cre-Tat intracerebroventricular injection, this sequestering of Otx2 in CSF led to ~10% decrease in OTX2 levels within V-SVZ (Fig. 4B,C), although it was not statistically significant given the large distribution of OTX2 mean intensity per cell (Fig. 4C). Subjecting these mice to the BrdU paradigm for OB integration (Fig. 4D) revealed a decrease in newborn neurons in the GCL of Cre-Tat-injected animals and no significant change in the GL (Fig. 4E). TUNEL assay revealed no change in neuroblast survival on arrival in the OB (Fig. 4F). Together, these results are similar to what was observed in Otx2-lox mice (Fig. 1F,H) and suggest that the transfer of OTX2 from CSF to V-SVZ plays a significant role in regulating adult neurogenesis. The accumulation of OTX2 protein in supporting cells (Fig. 3) within the niche further suggests that OTX2 regulates V-SVZ neurogenesis through modification of the niche microenvironment.

**OTX2 regulates astrocyte factors**

As we observe OTX2 internalization all along the migrating route of neuroblasts (Fig. 3) and found decreased neuroblast migration (Fig. 1N) with no change in cell survival
proliferation (Fig. 1K), we focused on a possible role for astrocytes found in both V-SVZ and RMS. Several receptors and factors are expressed in V-SVZ and RMS astrocytes that could potentially alter microenvironment composition and signaling. These include ECM proteins such as thrombospondin (Thbs1 and Thbs4) and tenascin-C (Tnc; Jankovski and Sotelo, 1996; Girard et al., 2014) and signaling molecules such as Robo and Eph receptors along with Ephrin ligands (Kaneko et al., 2010; Ming and Song, 2011; Falcão et al., 2012; Gengatharan et al., 2016; Todd et al., 2017), which may be under transcriptional control of OTX2 (Gherzi et al., 1997; Boncinelli and Morgan, 2001; Hoch et al., 2015; Peña et al., 2017). Expression analysis on V-SVZ microdissection lysates from the scFv-Otx2 non-cell-autonomous OTX2 knock-down model showed that EphrinA1, Thbs1, Thbs4, and Tnc were upregulated in V-SVZ (Fig. 5A). We also found that both Thbs4 and Tnc were upregulated in V-SVZ of Cre-Tat-injected Otx2-lox mice (mean ± SD: 304.6 ± 114.5% of vehicle (p = 0.0001) and 201.1 ± 94% of vehicle (p = 0.0037), respectively), reinforcing the similarity between both mouse models.

To confirm that supporting astrocytes are directly implicated in these changes in the expression of ECM and signaling factors, we turned to an in vitro astrocyte model involving aged astrocytes from newborn mouse cortex to

provide mature astrocytes that do not contain NSCs typical of V-SVZ cultures. Indeed, cultured late juvenile and adult cortex astrocytes do not give rise to neurons, while cultured V-SVZ astrocytes retain this potential (Laywell et al., 2000). However, astrocyte cultures derived from early juvenile mouse cortex show low Thbs4 expression (Benner et al., 2013), and cultured astrocytes typically show enriched expression of Thbs1 and repression of Thbs4 compared with their in vivo counterparts (Cahoy et al., 2008; Eroglu, 2009). While astrocytes in our in vitro model do not perfectly represent isolated V-SVZ supporting cells, they are suitable for assessing non-cell-autonomous OTX2 activity on mature and differentiated astrocytes given the absence of confounding NSCs. Consistent with changes observed in vivo, treatment with OTX2 protein resulted in the downregulation of EphrinA1, Thbs1, and Tnc (Fig. 5B), with the exception of Thbs4, which is not expressed in our cultured astrocytes and is in keeping with previous studies. In this in vitro paradigm, OTX2 was also found to regulate EphrinA2 and Eph4 expression, which further highlights differences with adult V-SVZ astrocytes. Nonetheless, these results are in agreement with OTX2 transfer to niche astrocytes to regulate neurogenesis by controlling ECM composition and signaling.

Discussion

OTX2 homeoprotein was previously found to act non-cell-autonomously in cortical interneurons (Sugiyama et al., 2008; Spatazza et al., 2013; Lee et al., 2017). The Otx2 locus is not active in the V-SVZ and RMS, but the protein can be immuno precipitated, indicating that OTX2 homeoprotein transfers not only into several distant cortical regions but also into regions proximal to the lateral ventricles. In the cortex, OTX2 is specifically internalized by parvalbumin interneurons, which have a unique and stable ECM called perineuronal nets (PNNs) that often stain for the lectin Wisteria floribunda agglutinin (WFA; Sugiyama et al., 2008). The specificity of internalization arises from a glycosaminoglycan-binding motif in OTX2 protein (Beurdeley et al., 2012; Lee et al., 2017), and although specific target glycosaminoglycans of OTX2 have yet to be identified, OTX2 preferentially binds disulfated chondroitin sulfate proteoglycans (Beurdeley et al., 2012; Miyata et al., 2012; Bernard and Prochiantz, 2016). However, staining for WFA is not detected in the V-SVZ (data not shown), which is not surprising given that PNNs are synonymous with consolidation of ECM and a break on plasticity—events that would counter the function of the neurogenic niche. The hypothesis of ECM–OTX2 interaction accounting for the specific internalization remains the most plausible, given that homeoprotein cell-surface receptors have not been found (Bernard and Prochiantz, 2016). Thus, the specificity of OTX2 for astrocytes within the V-SVZ and RMS suggests that they are expressing glycosaminoglycans with high affinity for OTX2.

Through specific conditional recombination in the ChP of two mouse models, similar decreases in neurogenesis were observed. In Otx2-lox mice, recombination results in loss of local OTX2 expression in the ChP, while in scfV-Otx2 mice it results in sequestering OTX2 in the CSF due to single-chain antibody secretion by the ChP (Bernard et al., 2016). The first model includes both potential cell-autonomous effects of loss of OTX2 in the ChP as well as potential non-cell-autonomous effects through reduced levels of secreted OTX2. The second model comprises only non-cell-autonomous effects as only secreted OTX2 is affected. This is confirmed by the absence of autocrine effects (i.e., CSF OTX2 signaling on ChP) assessed by Chp mRNA levels of OTX2 transcription targets on scFv expression (Bernard et al., 2016). Since both models provide a similar reduction in the number of newborn neurons, it suggests that OTX2 non-cell-autonomous function is of primary importance for adult neurogenesis. Interestingly, we observe an effect despite a nonsignificant reduction in OTX2 accumulation in V-SVZ, which is likely due in part to the large distribution of mean OTX2 staining intensity. Small (~20%) decreases in OTX2 in adult mouse visual cortex induce cortical plasticity (Spatazza et al., 2013; Bernard et al., 2016), and OTX2 transcriptional targets can be activated at one concentration of OTX2 yet be suppressed at lower or higher concentrations (Apulei et al., 2018). Concentration-dependent targets of homeoprotein are shown to be dependent on chromatin state, whereby some targets are concentration insensitive while others are highly concentration sensitive (Hannon et al., 2017). Indeed, we find significant changes in some but not all putative targets of OTX2 in the V-SVZ despite the potentially subtle changes in OTX2 accumulation.

Previous studies on the role of factors secreted by the ChP mainly show effects on the proliferation of NSCs and transit-amplifying cells, as well as effects on maintaining NSC quiescence and the migration of neuroblasts (Bjornsson et al., 2015; Silva-Vargas et al., 2016). These factors were found to signal through quiescent and/or activated NSCs, such as for BMP5, IGF2, or NT-3 (Delgado et al., 2014; Ziegler et al., 2015; Silva-Vargas et al., 2016), or were found to signal directly through neuroblasts to regulate migration, such as for SLIT1/2 (Nguyen-Ba-Charvet et al., 2004). Interestingly, ROBO2 is expressed by supporting astrocytes within the V-SVZ and RMS and influences the migration of neuroblasts, which express SLIT1 (Kaneko et al., 2010). This suggests that SLIT1/2 from ChP can also be signaling through supporting astrocytes. We find the ChP knockdown of OTX2 reduces GCL newborn neurons without significantly modifying of cell proliferation or cell death but by modifying neuroblast migration into the RMS. However, one might expect reduced neuroblast migration to lead to a proportional reduction in dying neuroblasts. Yet cell death is difficult to study in this population given the spatiotemporal heterogeneity of their death and the high variability in their detection (Ryu et al., 2016). Thus, we cannot formally exclude that OTX2 is also affecting cell death. Nonetheless, OTX2 protein transfers in GFAP-positive cells in the V-SVZ, in the majority of GFAP-positive cells in the RMS, and in ependymal cells of the V-SVZ; this profile points to
modification of the neurogenic niche instead of direct modification of progenitor activity. 

Given the precedent of ECM and supporting astrocytes for regulating neuroblast migration (Gengatharan et al., 2016; Kaneko et al., 2017), we examined OTX2-dependent expression of local ECM and signaling molecules expressed within V-SVZ and RMS. The RMS is composed of a compacted neuroblast network forming chains that migrate along blood vessels and are surrounded by astrocytic processes (Lois et al., 1996; Whittman et al., 2009). While it is clear that RMS-associated astrocytes interact with neuroblasts (Kaneko et al., 2010), the role of astrocytes for neuroblast migration is not well known. Studies show that neurogenesis is impacted by the composition of ECM in stem cell niches (Dityatev et al., 2010), which include astrocyte-derived TNC and THBS4 in V-SVZ and RMS (Jankovski and Sotelo, 1996; Benner et al., 2013; Girard et al., 2014), and OTX2 has been shown to regulate Tnc and Thbs4 transcription (Gherzi et al., 1997; Peña et al., 2017). While Tnc knock-out mice show no signs of altered adult neurogenesis (Kazanis et al., 2007), Thbs4 knock-out adult mice show reduced newborn neurons in the OB, yet no defect of embryonic neurogenesis (Girard et al., 2014). Cell-autonomous OTX2 expression was found to parallel Thbs4 expression in the retina (Housset et al., 2013), suggesting that OTX2 activity is context dependent, as previously suggested (Buecker et al., 2014). However, given the global dysregulation observed, we cannot come to a conclusion on the role of the different ECM molecules and interacting proteins. Nevertheless, changes in V-SVZ expression of Tnc and Thbs4 on Otx2 knockdown are in keeping with a transcriptional role for non-cell-autonomous OTX2 in astrocytes.

As OTX2 was found in RMS astrocytes and signalization with neuroblasts is still an open question (Chaker et al., 2016), we tested whether genes coding for migration and signaling factors might be modified in our models. Robo2 is strongly expressed in RMS astrocytes and is required for proper RMS organization and guidance of neuroblasts (Kaneko et al., 2010), and it has been hypothesized that astrocyte-derived laminin helps to form RMS scaffold for neuroblast migration (Belvindrah et al., 2007). Also, EphA4 and EphrinA2 are expressed in RMS and V-SVZ, supporting astrocytes (along with other combinations of Ephs and Ephrins), and EPHA4 has been shown to be critical for maintaining a compact and organized RMS (Todd et al., 2017). While OTX2 has been shown to bind Robo2 promoter (Hoch et al., 2015) and to regulate Ephrin-A2 (Rhinn et al., 1999), we did not detect any changes in V-SVZ expression after OTX2 knockdown. However, OTX2 affected expression more widely in cultured mature astrocytes, including the expression of EphA4 and EphrinA2, suggesting that it has the potential to influence RMS organization and/or that its activity is differentially regulated among astrocyte subtypes. While these cultured astrocytes are not derived from V-SVZ, they reflect better the activity of OTX2 in supporting astrocytes given that V-SVZ cultures are dominated by GFAP-expressing NSCs. This in vitro model confirms that transfer of OTX2 into V-SVZ can regulate the expression of genes found in supporting astrocytes.

Our results add to the growing research on homeoprotein transduction (Di Nardo et al., 2018) and add to the complexity of ChP function, which is essential for brain homeostasis and neuroimmune regulation (Spector et al., 2015; Ghersi-Egea et al., 2018). OTX2 signaling through the CSF to cortical interneurons has been shown to regulate brain plasticity throughout the cortex and impact higher cognitive functions. We must now consider that ChP-derived OTX2 accumulates in diverse regions of the brain and that altering its concentration within CSF can influence a wide range of brain functions. Within the V-SVZ, OTX2 regulates ECM molecules and factors that likely impact neuroblast migration and ultimately newborn neuron numbers. These findings reinforce both ChP and V-SVZ non-neurogenic astrocytes as key niche compartments affecting adult neurogenesis.
