Gap Amplification for Small-Set Expansion via Random Walks

Prasad Raghavendra and Tselil Schramm

Abstract

In this work, we achieve gap amplification for the Small-Set Expansion problem. Specifically, we show that an instance of the Small-Set Expansion Problem with completeness \( \varepsilon \) and soundness \( \frac{1}{2} \) is at least as difficult as Small-Set Expansion with completeness \( \varepsilon \) and soundness \( f(\varepsilon) \), for any function \( f(\varepsilon) \) which grows faster than \( \sqrt{\varepsilon} \). We achieve this amplification via random walks – the output graph corresponds to taking random walks on the original graph. An interesting feature of our reduction is that unlike gap amplification via parallel repetition, the size of the instances (number of vertices) produced by the reduction remains the same.
1 Introduction

The small-set expansion problem refers to the problem of approximating the edge expansion of small sets in a graph. Formally, given a graph $G = (V, E)$ and a subset of vertices $S \subseteq V$ with $|S| \leq |V|/2$, the edge expansion of $S$ is

$$\phi(S) = \frac{E(S, \bar{S})}{\text{vol}(S)},$$

where $\text{vol}(S)$ refers to the fraction of all edges of the graph that are incident on the subset $S$. The edge expansion of the graph $G$ is given by $\phi_G = \min_{S \subseteq V, \text{vol}(S) \leq 1/2} \phi(S)$. The problem of approximating the value of $\phi_G$ is the well-studied uniform sparsest cut problem [LR99, ARV04, ALN08].

In the small-set expansion problem, the goal is to approximate the edge expansion of the graph at a much finer granularity. Specifically, for $\delta > 0$ define the parameter $\phi_G(\delta)$ as follows:

$$\phi_G(\delta) = \min_{S \subseteq V, \text{vol}(S) \leq \delta} \phi(S).$$

The problem of approximating $\phi_G(\delta)$ for all $\delta > 0$ is the small-set expansion problem.

The small-set expansion problem has received considerable attention in recent years due to its close connections to the unique games conjecture. To describe this connection, we will define a gap version of the problem.

**Definition 1.** For constants $0 < s < c < 1$ and $\delta > 0$, the $SSE(\delta, s)$ problem is defined as follows: Given a graph $G = (V, E)$ distinguish between the following two cases:

- $G$ has a set $S$ with $\text{vol}(S) \in [\delta/2, \delta]$ with expansion less than $1 - c$
- All sets $S$ with $\text{vol}(S) \leq \delta$ in $G$ have expansion at least $1 - s$.

We will omit the subscript $\delta$ and write $SSE(c, s)$ when we refer to the $SSE(\delta, c, s)$ problem for all constant $\delta > 0$.

Recent work by Raghavendra and Steurer [RS10] introduced the following hardness assumption and showed that it implies the unique games conjecture.

**Hypothesis 1.1.** For all $\epsilon > 0$, there exists $\delta > 0$ such that $SSE(\delta, 1 - \epsilon, \epsilon)$ is NP-hard.

**Theorem 1.2.** [RS10] The small set expansion hypothesis implies the unique games conjecture.

Moreover, the small set expansion hypothesis is shown to be equivalent to a variant of the Unique Games Conjecture wherein the input instance is promised to be a small-set expander [RST12]. Assuming the small-set expansion hypothesis, hardness results have been obtained for several problems including Balanced Separator, Minimum Linear Arrangement [RST12] and the problem of approximating vertex expansion [LRV13].

In this work, we will be concerned with gap amplification for the small set expansion problem. Gap amplification refers to an efficient reduction that takes a weak hardness result for a problem $\Pi$ with a small gap between the completeness and soundness and produces a strong hardness with a much larger gap. Formally, this is achieved via an efficient reduction from instances of problem $\Pi$ to harder instances of the same problem $\Pi$. Gap amplification is a crucial step in proving hardness of approximation results. An important example of gap amplification is the parallel repetition of 2-prover 1-round games or Label Cover. Label cover is a constraint satisfaction problem which is the starting point for a large number of reductions in hardness of approximation [H01]. Starting with the PCP theorem, one obtains a weak hardness for label cover with a gap of 1 vs $1 - \beta_0$ for some tiny absolute constant $\beta_0$ [ALM+98]. Almost all label-cover based hardness results rely on the much stronger 1 vs $\epsilon$ hardness for label cover.
obtained by gap amplification via the parallel repetition theorem of Raz [Raz98]. More recently, there have been significant improvements and simplifications to the parallel repetition theorem [Rao08, Hol07, DS13].

It is unclear if parallel repetition could be used for gap amplification for small set expansion. Given a graph $G$, the parallel repetition of $G$ would consist of the product graph $G^k$ for some large constant $R$. Unfortunately, the product graph $G^k$ can have small non-expanding sets even if $G$ has no small non-expanding sets. For instance, if $G$ has a balanced cut then $G^k$ could have a non-expanding set of volume $\frac{1}{k}$.

In this work, we show that random walks can be used to achieve gap amplification for small set expansion. Specifically, given a graph $G$ the gap amplification procedure constructs $G'$ on the same set of vertices as $G$, but with edges corresponding to $t$-step lazy random walks in $G$. Using this approach, we are able to achieve the following gap amplification.

**Theorem 1.** Let $f$ be any function such that $\lim_{\epsilon \to 0} \frac{f(\epsilon)}{\sqrt{\epsilon}} \to \infty$. Then

If for all $\epsilon > 0$, $\text{SSE}'(1 - \epsilon, 1 - f(\epsilon))$ is NP-hard then for all $\eta > 0$, $\text{SSE}(1 - \eta, 1/2)$ is NP-hard.

We remark here that the result has some discrepancy in the set sizes between the original instance and the instance produced by the reduction. For this reason, the reduction has to start with a slightly different version of the Small set expansion problem $\text{SSE}'$ (See Definition 2).

The above result nicely complements the gap amplification result for the closely related problem of Unique Games obtained via parallel repetition [Rao08]. For the sake of completeness we state the result below.

**Theorem 1.3.** [Rao08] Let $f$ be any function such that $\lim_{\epsilon \to 0} \frac{f(\epsilon)}{\sqrt{\epsilon}} \to \infty$. Then

If for all $\epsilon > 0$ if $\text{UG}(1 - \epsilon, 1 - f(\epsilon))$ is NP-hard then for all $\eta > 0$, $\text{UG}(1 - \eta, 1/2)$ is NP-hard.

Note that the size of the instance produced by our reduction remains bounded by $O(n^2)$. In fact, the instance produced has the same number of vertices but possibly many more edges. This is in contrast to parallel repetition wherein the size of the instance grows exponentially in the number of repetitions used.

Technically, the proof of the result is very similar to an argument in the work of Arora, Barak and Steurer [ABS10] to show that graphs with sufficiently high threshold rank cannot be small-set expanders (see Steurier’s thesis [Ste10] for an improved version of the result). The work of O’Donnell and Wright [OW12] recast these arguments using continuous-time random walks instead of lazy-random walks, yielding cleaner and more general proofs. In this work, we will reuse the proof technique and obtain upper and lower bounds for the expansion profile of lazy random walks (see Theorem 3.1). These upper and lower bounds immediately imply the desired gap amplification result for small-set expansion.

Subsequent to our work, Kwok and Lau [KL14] have obtained a stronger analysis of our gap amplification theorem, yielding almost tight bounds.

## 2 Preliminaries

Unless otherwise specified, we will be concerned with an undirected graph $G = (V, E)$ with $n$ vertices and associated edge weights $w : E \to \mathbb{R}^+$. The degree of vertex $i$ denoted by $d(i) = \sum_{(i,j) \in E} w(i, j)$. The volume of a set $S \subseteq V$ is defined to be $\text{vol}(S) = \sum_{i \in S} d(i)$. Henceforth, we will assume that the total volume is 1, i.e., $\sum_{i \in V} d(i) = 1$. The adjacency matrix $A$ of the graph $G$ has entries $A_{ij} = w(i, j)$. The degree matrix $D$ is a $n \times n$ diagonal matrix with $D_{ii} = d(i)$.

**Expansion profile.** The expansion profile of a graph is defined as follows.
**Definition 2.1.** For a graph $G$, define the expansion profile $\phi_G : \mathbb{R}^+ \to [0, 1]$ as

$$\phi_G(\delta) = \min_{S \subseteq V, \text{vol}(S) \leq \delta} \phi(S)$$

where $\phi(S) = \frac{E(S, S)}{\text{vol}(S)}$.

**Lazy Random Walks.** The transition matrix for a lazy random walk on $G$ is given by

$$M = \frac{1}{2}(I + D^{-1}A)$$

The lazy random walk corresponds to staying at the same vertex with probability $\frac{1}{2}$, and moving to a random neighbor with probability $\frac{1}{2}$. We will let $G'$ denote the graph corresponding to the $t$-step lazy random walk. The adjacency matrix of $G'$ is given by $DM'$.

We recall a few standard facts about lazy random walks here.

**Fact 2.2.** If $G$ is a graph with adjacency matrix $A$, then $G'$s lazy random walk operator $M = \frac{1}{2}(I + D^{-1}A)$ has the property that $\|D^{\nicefrac{1}{2}}Mv\|_2^2 = v^TDM^2v$ for any vector $v$.

**Proof.** We use the fact that $M = \frac{1}{2} D^{-\nicefrac{1}{2}} (I + D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}}) D^{\nicefrac{1}{2}}$:

$$\|D^{\nicefrac{1}{2}}Mv\|_2^2 = \frac{1}{2} v^T M^TDMv$$

$$= \frac{1}{2} v^T D^{\nicefrac{1}{2}} (I + D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}}) D^{\nicefrac{1}{2}} DD^{\nicefrac{1}{2}} (I + D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}}) D^{\nicefrac{1}{2}} v$$

$$= \frac{1}{2} v^T D^{\nicefrac{1}{2}} (I + D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}})^2 D^{\nicefrac{1}{2}} v$$

$$= v^T D^2 v,$$

as desired. □

**Fact 2.3.** If $G$ is a graph with adjacency matrix $A$, then for the lazy random walk operator $M = \frac{1}{2}(I + D^{-1}A)$, we have

$$\|D^{\nicefrac{1}{2}}v\|_2^2 = v^TDv \geq v^TDMv \geq v^T D^2 v = \|D^{\nicefrac{1}{2}}Mv\|_2^2.$$  

**Proof.** Since the eigenvalues $\lambda_i$ of $D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}}$ are between $[-1, 1]$, the eigenvalues of $M' = \frac{1}{2}(I + D^{-\nicefrac{1}{2}} AD^{-\nicefrac{1}{2}})$ are $\mu_i = \frac{1}{2}(1 + \lambda_i)$, and so $\mu_i \in [0, 1]$. Let $D^{\nicefrac{1}{2}}v = \sum \alpha_i u_i$ be the decomposition of $D^{\nicefrac{1}{2}}v$ in terms of the eigenvectors of $M'$. Then we have

$$D^{\nicefrac{1}{2}}Mv = M'D^{\nicefrac{1}{2}}v = \sum \alpha_i \mu_i u_i,$$

and so $v^TDv = \sum \alpha_i^2$, $v^TDMv = \sum \alpha_i^2 \mu_i$, and $v^T D^2 v = \sum \alpha_i^2 \mu_i^2$. Since $\mu_i \in [0, 1]$, we have $v^TDv \geq v^TDMv \geq v^T D^2 v$, as desired. □

**Fact 2.4.** For the lazy random walk operator $M = \frac{1}{2}(I + D^{-1}A)$ and any vector $v \in \mathbb{R}^V$, $v \geq 0$ we have

$$\|Dv\|_1 = \|DMv\|_1.$$  

**Proof.** Let $v \in \mathbb{R}^V$. We have

$$\|DMv\|_1 = 1^T D (\frac{1 + D^{-1}A}{2}) v = \frac{1}{2} (1^T Dv + (1^T A)v) = \|Dv\|_1,$$

where the last inequality follows because $1^T D = 1^T A$. □
Small-Set Expansion Problem. The formal statement of the SSE’ problem is as follows.

Definition 2. For constants $0 < s < c < 1$ and $\delta > 0$, the Small-Set Expansion problem $\text{SSE}'(c, s)$ is defined as follows: Given a graph $G = (V, E)$, distinguish between the following two cases:
- $G$ contains a set $S$ such that $\text{vol}(S) \in [\delta/2, \delta]$ and $\phi(S) \leq 1 - c$
- All sets $S$ with $\text{vol}(S) \leq 8\delta$ in $G$ have expansion $\phi(S) \geq 1 - s$.

The key difference from $\text{SSE}_\delta(c, s)$ is that the soundness is slightly stronger in that even sets of size $8\delta$ have expansion at least $1 - s$.

Organization. In Section 3, we will obtain upper and lower bounds (Theorem 3.1) for expansion profile of lazy random walks. Subsequently, we use these bounds to conclude the main result of the paper in Section 4. In Appendix A, we give a reduction that establishes the equivalence of the search versions of two different notions of Small-Set Expansion. We also present a reduction from SSE on irregular graphs to SSE on regular graphs in Appendix B. Finally, in Appendix C, we discuss some obstacles encountered in applying this reduction to the Unique Games problem.

3 Expansion profile of lazy random walks

Let $G = (V, E)$ be a graph with adjacency matrix $A$, and diagonal degree matrix $D$. The transition matrix for a lazy random walk on $G$ is $M = \frac{1}{2}(I + D^{-1}A) = \frac{1}{2}D^{-\frac{1}{2}}(I + D^{-\frac{1}{2}}AD^{-\frac{1}{2}})D^{\frac{1}{2}}$.

For every $t \in \mathbb{N}$, let $G^t$ denote the graph corresponding to the $t$-step lazy random walk whose adjacency matrix is given by $DM^t$. We will prove the following theorem about the expansion profile of $G^t$.

Theorem 3.1. For all $t \in \mathbb{N}$ and $\eta, \delta \in (0, 1]$, if $G^t$ denotes the graph corresponding to the $t$-step lazy random walk in a graph $G = (V, E)$ then,

$$\min \left( 1 - \left( 1 - \frac{\phi_G^2(\delta)}{32} \right)^\frac{t}{2} \right), 1 - \eta \right) \leq \phi_{G^t}(\delta) \leq \frac{t}{2} \cdot \phi_G(\delta)$$

We will split the proof of the above theorem into two parts: Lemma 3.2 and Lemma 3.3

Lemma 3.2. For every subset $S \subseteq V$,

$$\phi_{G^t}(S) \leq \frac{t}{2} \cdot \phi_G(S),$$

and therefore $\phi_{G^t}(\delta) \leq \frac{t}{2} \cdot \phi_G(\delta)$.

Proof. Fix a subset $S \subseteq V$. From [GT12], we have that the probability $p(t)$ that a lazy random walk stays entirely in $S$ for $t$ steps is bounded below by

$$p(t) \geq \left( 1 - \frac{1}{2} \phi(S) \right)^t.$$

Now, the expansion of $S$ in $G^t$ is the probability of leaving the set on the $t$th step of the random walk, which is at most $1 - p(t)$. Hence,

$$\phi_{G^t}(S) \leq 1 - p(t) \leq 1 - \left( 1 - \frac{1}{2} \phi(S) \right)^t \leq \frac{t}{2} \phi(S),$$

as desired. The result immediately follows for all sets of volume $\leq \delta$. \qed
Lemma 3.3. For all $t, \eta$,

$$\phi_G(\delta) \geq \min \left\{ 1 - \left(1 - \frac{\beta_2^2}{8} \right)^t, 1 - \eta \right\}.$$

We prove this lemma by contradiction, by showing that if the expansion in the final graph is not large enough then there exists a vector with bounded Rayleigh quotient with respect to the original graph, from which we can extract a non-expanding set. The intuition is that the expansion of a set in the final graph $DM^t$ corresponds to the neighborhood of the random walk after $t$ steps, and if the neighborhood is not large enough after $t$ steps, there must be at least one step (or application of $M$) during which it did not grow.

Proof. Suppose by way of contradiction that this is not the case. Let $\beta = \phi_G(\frac{4\delta}{\eta})$ and let $\delta' = \frac{4\delta}{\eta}$. Further, let $\beta = \frac{1}{2}\beta$.

Let $S$ be a set of volume at most $\delta \cdot \text{vol}(V)$ such that

$$\phi_G(S) \leq \min \left\{ 1 - \left(1 - \frac{\beta_2^2}{8} \right)^t, 1 - \eta \right\}.$$  \hfill (3.1)

Let $v_0 = 1_S$ be the vector corresponding to the indicator function of the set $S$. Define $v_i = M^tv_0$, and for the diagonal degree matrix $D$ of $A$, define $w_i = D^iv_i$. Note that $\|w_0\|^2 = \text{vol}(S)$, and $\|Dv_0\|_1 = \text{vol}(S)$. By Fact 2.4 we also have $\|Dv_i\|_1 = \text{vol}(S)$ for all $i$.

We first lower-bound $\|w_i\|_2$. By definition of expansion,

$$\phi_G(S) = 1 - \frac{v_0^TDM^iv_0}{v_0^TDv_0}$$

which by Fact 2.2 implies that $\|D^{\frac{1}{2}}M^\frac{1}{2}v_0\|^2 = \text{vol}(S)(1 - \phi_G(S))$. Now, using (3.1) we get

$$\|w_i\|^2 = \|D^{\frac{1}{2}}M^\frac{1}{2}v_0\|^2 = \text{vol}(S)(1 - \phi_G(S)) \geq \text{vol}(S) \cdot \max \left( \eta, (1 - \frac{1}{8}\beta^2)^t \right).$$  \hfill (3.2)

By Fact 2.3, we have $\|w_i\|_2 \geq \|w_{i+1}\|_2 > 0$ for all $i$, and (3.2) holds for all $i < \frac{1}{2}$.

We now assert that there must be some $i$ for which

$$\frac{\|w_{i+1}\|^2}{\|w_i\|^2} > 1 - \frac{1}{4}\beta^2.$$

To see this, consider the product of all such terms for $i < \frac{1}{2}$. Some algebraic simplification shows that

$$\prod_{i=0}^{\frac{1}{2} - 1} \frac{\|w_{i+1}\|^2}{\|w_i\|^2} = \frac{\|w_{\frac{1}{2}}\|^2}{\|w_0\|^2} > \frac{(1 - \frac{1}{8}\beta^2)^t \cdot \text{vol}(S)}{\text{vol}(S)} = (1 - \frac{1}{8}\beta^2)^t,$$

where the second-to-last inequality follows from (3.2). Thus for some $i < \frac{1}{2}$ we have

$$\frac{\|w_{i+1}\|^2}{\|w_i\|^2} > \left(1 - \frac{1}{8}\beta^2\right)^t > 1 - \frac{1}{4}\beta^2.$$

Then let $w_i$ be the vector corresponding to the first $i$ for which $\|w_{i+1}\|^2 > (1 - \frac{1}{4}\beta^2)\|w_i\|^2$.  

6
Since \( w_{i+1} \) is obtained from \( v_i \) via one step of a lazy random walk and a normalization, we can bound the Rayleigh quotient of \( v_i \) with respect to the Laplacian of \( DM = \frac{1}{2}(D + A) \):

\[
\frac{v_i^T D(I-M)v_i}{v_i^T Dv_i} = 1 - \frac{v_i^T DMv_i}{v_i^T Dv_i},
\]

by Fact 2.3,

\[
\leq 1 - \frac{v_i^T DM^2v_i}{v_i^T Dv_i}
\]

and by Fact 2.2,

\[
= 1 - \frac{||w_{i+1}||_2^2}{||w_i||_2^2}
\]

\[
\leq \frac{1}{4} \beta^2. \tag{3.3}
\]

We now truncate the vector \( v_i \), then run Cheeger’s algorithm on the truncated vector in order to find a non-expanding small set, and thus obtain a contradiction. Let \( \theta = \frac{\eta}{4} \). We take the truncated vector

\[
z_i(j) = \begin{cases} v_i(j) - \theta & v_i(j) \geq \theta \\ 0 & \text{otherwise} \end{cases}.
\]

By Fact 2.4, \( Dv_i \) has \( L_1 \) mass \( \text{vol}(S) \). Thus, the total volume of the set \( S_z \) of vertices with nonzero support in \( z_i \) is

\[
\text{vol}(S_z) = \sum_{v_i(j) > \theta} d(j) \leq \sum_{v_i(j) > \theta} \frac{1}{\theta} d(j) v_i(j) \leq \frac{1}{\theta} \cdot ||Dv_i||_1 = \frac{4 \text{vol}(S)}{\eta}
\]

Hence any subset of \( S_z \) has volume at most \( \frac{4 \text{vol}(S)}{\eta} \).

For the vector \( v_i \), we know that \( ||Dv_i||_1 = \text{vol}(S) \). Moreover using (3.2),

\[
||D^{1/2}v_i||_2^2 = ||w_i||_2^2 \geq ||v_i/2||_2^2 \geq \eta \text{vol}(S).
\]

Applying Lemma 1 to \( v_i \) and \( z_i \) to conclude,

\[
\frac{z_i^T D(I-M)z_i}{z_i^T Dz_i} \leq 2 \frac{v_i^T D(I-M)v_i}{v_i^T Dv_i}.
\]

Using (3.3), this implies the following bound on the Rayleigh quotient of \( z_i \),

\[
\frac{z_i^T D(I-M)z_i}{z_i^T Dz_i} \leq \frac{1}{2} \beta^2.
\]

Thus, when we run Cheeger’s algorithm on \( z_i \), we get a set of volume at most \( \frac{4 \text{vol}(S)}{\eta} \) and of expansion less than \( \tilde{\beta} \) in \( DM \), and therefore less than \( \beta \) in \( G \). Since \( \beta = \phi_G(\frac{4 \eta}{\eta}) \), this is a contradiction. This completes the proof of Lemma 3.3. \( \square \)

The following lemma, which gives an upper bound on the Rayleigh quotient of a truncated vector, is a slight generalization of Lemma 3.4 of [ABS10].
Lemma 1. Let \( x \in \mathbb{R}^V \) be non-negative, let \( L \) be the weighted Laplacian of a graph \( G = (V,E) \) with weights \( w(i,j) \) and degree matrix \( D \). Suppose that

\[
4\theta \|Dx\|_1 \leq \|D^{1/2}x\|_2^2 \tag{3.4}
\]

Then for the threshold vector \( y \) defined by

\[
y(i) = \begin{cases} 
  x(i) - \theta & x(i) > \theta \\
  0 & \text{otherwise}
\end{cases}
\]

we have

\[
\frac{y^T Ly}{y^T Dy} \leq 2 \cdot \frac{x^T Lx}{x^T Dx}
\]

Proof. First, we show \( y^T Ly \leq x^T Lx \).

\[
y^T Ly = \sum_{(i,j) \in E} w(i,j)(y(i) - y(j))^2
\]

\[
= \sum_{(i,j) \in E} w(i,j)(x(i) - x(j))^2 + \sum_{(i,j) \in E} w(i,j)(x(i) - \theta)^2
\]

\[
\leq \sum_{(i,j) \in E} w(i,j)(x(i) - x(j))^2
\]

\[
= x^T Lx,
\]

where the second-to-last inequality follows from the fact that if \( y(i) = 0 \), then \( x(i) \leq \theta \).

Now, we show that \( y^T Dy \geq \frac{1}{2} x^T Dx \). First, we note that \( d(i)y(i)^2 \geq d(i)x(i)^2 - 2\theta d(i)x(i) \) for all \( k \).

Thus,

\[
\sum_{i \in V} d(i)y(i)^2 \geq \sum_{i \in V} d(i)x(i)^2 - 2\theta \sum_{i \in V} d(i)x(i)
\]

\[
= \left( \sum_{i \in V} d(i)x(i)^2 \right) - 2\theta \left( \sum_{i \in V} d(i)x(i) \right)
\]

\[
\geq \frac{1}{2} \sum_{i \in V} d(i)x(i)^2
\]

Where the last inequality follows by assumption \( (3.4) \).

Thus, we have

\[
\frac{y^T Ly}{y^T Dy} \leq 2 \cdot \frac{x^T Lx}{x^T Dx}
\]

as desired. \( \square \)

4 Gap Amplification

In this section, we will prove Theorem 1 which we restate here for convenience.

Theorem 2. (Restatement of Theorem 1) Let \( f \) be any function such that \( \lim_{\varepsilon \to 0} \frac{f(\varepsilon)}{\sqrt{\varepsilon}} \to \infty \). Then

If for all \( \varepsilon > 0 \), \( SSE'(1 - \varepsilon, 1 - f(\varepsilon)) \) is NP-hard then for all \( \eta > 0 \) \( SSE(1 - \eta, 1/2) \) is NP-hard.
Proof. Fix $\epsilon$ small enough so that $\frac{64 \epsilon}{f'(\epsilon)} \leq \eta$. There exists such an $\epsilon$ since $\lim_{\epsilon \to 0} \frac{f(\epsilon)}{\sqrt{\epsilon}} \to \infty$. Fix $t = \frac{64}{f'(\epsilon)}$.

Given an instance $G$ of $SSE'(1 - \epsilon, 1 - f'(\epsilon))$, the reduction just outputs the graph $G_t$ obtained via $t$-step lazy random walks on $G$. Since the adjacency matrix of $G'$ can be calculated with $\log t$ matrix multiplications, this reduction clearly runs in time $O(n^3 \log t)$.

Completeness. If there exists a set of $S$ with $\text{vol}(S) \in [\delta/2, \delta]$ and $\phi_G(S) \leq \epsilon$ then by Lemma 3.2 the same set $S$ satisfies,

$$\phi_{G'}(S) \leq \frac{t}{2} \phi_G(S) = \Theta\left(\frac{\epsilon}{f'(\epsilon)^2}\right) \leq \eta$$

Soundness. If $\phi_G(8\delta) \geq f(\epsilon)$ then by applying Lemma 3.3

$$\phi_{G'}(\delta) \geq \min\left(1 - \left(1 - \frac{1}{32} f(\epsilon)^2\right)^t, \frac{1}{2}\right) \geq \frac{1}{2}$$

A Equivalence of Two Notions of the Small-Set Expansion Problem

There is a slightly different version of the Small-Set expansion decision problem that differs from Definition 1 in the soundness case.

Definition 3. For constants $0 < s < c < 1$, and $\delta > 0$, the Small-Set Expansion problem $SSE^\delta(c, s)$ is defined as follows: Given a graph $G = (V, E)$ with $\text{vol}(V) = N$, distinguish between the following two cases:

- $G$ has a set of volume in the range $\left[\frac{1}{2}\delta N, \delta N\right]$ with expansion less than $1 - c$
- All sets in $G$ of volume in the range $\left[\frac{1}{4}\delta N, \delta N\right]$ have expansion at least $1 - s$.

Clearly $SSE^\delta_0(c, s)$ is a harder decision problem than $SSE_0(c, s)$ since the soundness assumption is weaker. There is no known reduction from $SSE^\delta_0(c, s)$ to $SSE_0(c, s)$ that establishes the equivalence of the two versions. Here we observe that the search versions of these two problems are equivalent.

Proposition 1. For all $\delta_0, c, s > 0$ A search algorithm for $SSE_0(2c - 1, s)$ for $\delta \in [\delta_0/2, \delta_0]$ gives a search algorithm for $SSE^\delta_0(c, s)$ in the range $\delta \in [\delta_0/2, \delta_0]$.

Proof. Suppose we are given an algorithm $A$ that finds a set $S'$ of volume at most $\delta N$ and expansion less than $1 - s$ whenever there exists a set $S$ with $\text{vol}(S) \in [\frac{1}{4}\delta N, \delta N]$ and $\phi(S) \leq 2 - 2c$. We construct a set $S \subseteq V$ such that $\text{vol}(S) \in [\frac{1}{4}\delta N, \delta N]$ and $\phi(S) < 1 - s$. We proceed iteratively, as follows.

We start with an empty initial set, $S_{out}$, and with the full graph, $G_0 = G$. If $\text{vol}(S_{out}) \in [\frac{1}{4}\delta N, \delta N]$, we terminate and return $S_{out}$. Otherwise, at the $i$th step, we apply $A$ to $G_{i-1}$ to obtain a set $S_i$ of expansion less than $1 - s$. If $\text{vol}(S_i) \in [\frac{1}{4}\delta N, \delta N]$ return $S_i$, otherwise add the vertices in $S_i$ to $S_{out}$. We then set $G_i = G_{i-1} \setminus S_i$. If no such set can be found, then we terminate and return no.

Clearly, this algorithm terminates and runs in polynomial time. Suppose $S'$ is a nonexpanding set with $\text{vol}(S') \in [\frac{1}{4}\delta N, \delta N]$. As long as $S_{out}$ has volume smaller than $\frac{1}{4}\delta N$, $S' - S_{out}$ will have volume at least $\frac{1}{4}\delta N$ and expansion at most $2\phi(S') \leq 2 - 2c$. Hence by the assumption about algorithm $A$, it will return a set $S_i$ of expansion at most $1 - s$. The check of the volume of $S_i$ ensures that $S_{out}$ will never go from below the allowable volume range to above in a single step. Finally if $S_i$ was never returned for any step $i$, the union of all the sets $S_i$ has expansion at most $1 - s$ and volume in the range $[\delta N/4, \delta N]$.

B Reduction from Irregular Graphs to Regular Graphs

In this section, we present a reduction from small set expansion on irregular graphs to small set expansion on regular graphs. Specifically, we prove the following theorem.

**Theorem 3.** There exists an absolute constant $C$ such that for all $\gamma, \beta \in (0, 1)$ there is a polynomial time reduction from $\text{SSE}_\delta(1 - \gamma, 1 - \beta)$ on an irregular graph $G = (V, E)$ to $\text{SSE}_\delta(1 - \gamma, 1 - \beta/\gamma)$ on a 4-regular graph $G' = (V', E')$

**Proof.** The reduction is as follows: we replace each vertex $v \in V$ with a 3-regular expander $A_v$ on $\deg(v)$ vertices. Using standard constructions of 3-regular expanders, we can assume that the graphs $A_v$ have edge expansion at least $\kappa = 0.01$. Now, for each edge $(v, w) \in E$, we add an edge between a particular vertex in $A_v$ and $A_w$. The resulting graph on the expanders is $G'$, with $V' = \bigcup_{v \in V} A_v$. Note that $G'$ is $d$-regular, and that $|V'| = \sum_{v \in V} \deg(v) = \text{vol}(V)$, as desired.

For the completeness, we note that if a set $S \subset V$ with volume at most $\delta|V|$ has $\phi_C(S) < \gamma$, then the set $S' = \bigcup_{v \in S} A_v$ has the same number of edges leaving the set as $S$, and the number of vertices in the set is equal to $\text{vol}(S)$. Thus, $\phi_C(S') < \gamma/4$, as desired.

For soundness, suppose there is a set $S' \subset V'$ with $|S'| \leq \delta|V'|$ and $\phi_C(S') < \beta$. Then we can partition $S'$ into sets corresponding to each $A_v$; let $B_v = S' \cap A_v$. Then consider the set

$$S' = \bigcup_{|B_v| > \frac{1}{\kappa} |A_v|} A_v,$$

the set of $A_v$ that overlap with $S'$ by at least half. We will argue that $S'$ has expansion at most $\frac{10\beta}{\kappa}$ in $G'$. First, by definition of expansion we have

$$\beta \geq \phi_C(S') = \frac{\sum_{v \in V} E(B_v, S'_v)}{4\sum_{v \in V} |B_v|} = \frac{\sum_{v \in V} E(B_v, A_v) \setminus B_v + E(B_v, S'_v \setminus A_v)}{4\sum_{v \in V} |B_v|},$$

where we distinguish between boundary edges of $S'$ inside and outside of the $A_v$. In particular, we have

$$4\beta \sum_{v \in V} |B_v| \geq \sum_{v \in V} E(B_v, A_v) \setminus B_v.$$

Now, we bound from below the number of boundary edges within $A_v$. Since $A_v$ is an expander with expansion $\kappa$, we have

$$E(B_v, A_v) \setminus B_v \geq \kappa \cdot \min(|B_v|, |A_v \setminus B_v|).$$

Hence we will have,

$$S' \Delta S' = \sum_{v} \min(|B_v|, |A_v \setminus B_v|) \leq \frac{1}{\kappa} \sum_{v} E(B_v, A_v) \setminus B_v \leq \frac{4\beta}{\kappa} \sum_{v \in V} |B_v| = \frac{4\beta}{\kappa} |S'|.$$

Since $G'$ is a 4-regular graph, we can upper bound the expansion of $S'$ by

$$\phi_C(S') \leq \frac{E[S', S'_v] + 4|S' \Delta S'|}{4|S'| - 4|S' \Delta S'|} \leq \frac{4\beta|S'| + 16\delta|S'|}{4|S'| - 4|S'|} \leq \frac{\beta(1 + 4\delta)}{1 - 4\delta}$$

Thus, in $G$ the set $S = \{v \mid A_v \in S'\}$ has expansion at most $\frac{10\beta}{\kappa}$ and $\text{vol}(S) \in \left\{ \frac{1}{2} \delta \text{vol}(V), 2 \delta \text{vol}(V) \right\}$, as desired. \qed
C Discussion of Unique Games

The following simple example illustrates why a similar reduction will not work for Unique Games. Consider a unique games instance with two disconnected components, one of size $s \cdot n$ in which only $\frac{1}{2}$ of the constraints are satisfiable, and another component of size $(1 - s)n$ in which all constraints are perfectly satisfiable. In this case, running a random walk on the label-extended graph will not alter the number of satisfiable constraints.

A slight modification of this approach would at first seem to be a promising avenue for overcoming this example at first: reweight the graph of constraints by $(1 - w)$, and add to it an expander of weight $w$ with arbitrary constraints. Now, in the previous example, following the proof of our completeness case we observe that after $t$ steps of the random walk, the formerly perfectly satisfiable component has expansion at most $tw$, the soundness is at most $1 - t(w + rs)$. Similarly, in the completeness case, our reduction goes from completeness $1 - c$ to soundness $1 - t(c + w)$. Thus, because the added constraints contribute equally to the soundness of the bad example and the completeness in general, this approach does not overcome the problem of isolated components.
