SOME REMARKS ON THE \( n \)-LINEAR HILBERT TRANSFORM FOR \( n \geq 4 \)

CAMIL MUSCALU

Abstract. We prove that for every integer \( n \geq 4 \), the \( n \)-linear operator whose symbol is given by a product of two generic symbols of \( n \)-linear Hilbert transform type, does not satisfy any \( L^p \) estimates similar to those in H"older inequality. Then, we extend this result to multilinear operators whose symbols are given by a product of an arbitrary number of generic symbols of \( n \)-linear Hilbert transform kind. As a consequence, under the same assumption \( n \geq 4 \), these immediately imply that for any \( 1 < p_1, ..., p_n \leq \infty \) and \( 0 < p < \infty \) with \( 1/p_1 + ... + 1/p_n = 1/p \), there exist non-degenerate subspaces \( \Gamma \subseteq \mathbb{R}^n \) of maximal dimension \( n - 1 \), and Mikhlin symbols \( m \) singular along \( \Gamma \), for which the associated \( n \)-linear multiplier operators \( T_m \) do not map \( L^{p_1} \times ... \times L^{p_n} \) into \( L^p \). These counterexamples are in sharp contrast with the bilinear case, where similar operators are known to satisfy many \( L^p \) estimates of H"older type.

1. Introduction

Let \( n \geq 2 \). For \( \vec{\alpha} = (\alpha_1, ..., \alpha_{n-1}) \in \mathbb{R}^{n-1} \) an arbitrary vector, consider the expression

\[
\int_{\mathbb{R}^n} \text{sngn}(\xi + \alpha_1 \xi_1 + ... + \alpha_{n-1} \xi_{n-1}) \hat{f}(\xi) \hat{f_1}(\xi_1) ... \hat{f_{n-1}}(\xi_{n-1}) e^{2\pi i(\xi_1 + ... + \xi_{n-1})} d\xi d\xi_1 ... d\xi_{n-1}
\]

where \( f, f_1, ..., f_{n-1} \) are all Schwartz functions on the real line and \( x \) is a real number. If all the entries \( (\alpha_j)_j \) are different than 0 and 1 also different from each other, the \( n \)-linear operator from (1) is called the \( n \)-linear Hilbert transform and it will be denoted by \( nHT_{\alpha}(f, f_1, ..., f_{n-1})(x) \). Notice that if one erases the symbol

\[
\text{sngn}(\xi + \alpha_1 \xi_1 + ... + \alpha_{n-1} \xi_{n-1})
\]

from (1), the corresponding expression becomes the product of the functions involved

\[
f(x)f_1(x)...f_{n-1}(x)
\]

The main question about these operators is whether they satisfy estimates of H"older type, more precisely if there exist \( 1 < p_1, ..., p_n \leq \infty \) and \( 0 < p < \infty \) with \( 1/p_1 + ... + 1/p_n = 1/p \) so that \( nHT_{\alpha} \) can be naturally extended as a bounded \( n \)-linear operator from \( L^{p_1} \times ... \times L^{p_n} \) into \( L^p \).

The interest in their study comes from their close connection to the so called Calderón commutators [1], [3]. Indeed, a direct calculation shows that modulo a universal constant, one has the identity

\[
\int_{[0,1)^{n-1}} nHT_{\vec{\alpha}}(f, a, ..., a)(x)d\vec{\alpha} = p.v. \int_{\mathbb{R}} \frac{(A(x) - A(y))^{n-1}}{(x - y)^n} f(y)dy
\]

with \( A' = a \). As one can recognize, the expression on the right hand side is precisely the \((n-1)\)th commutator of Calderón [1], [3]. If \( n = 2 \) and \( \alpha \) is an arbitrary real number different than 0 and...
1, the bilinear Hilbert transform $2HT_\alpha$ does satisfy such estimates, thanks to the work of Lacey and Thiele from [8] and [9]. But for $n \geq 3$ no positive results are presently known.

There are two very natural ways to generalize these operators, which will be described next. First, for any $k \geq 1$ and arbitrary vectors $\vec{\alpha}_1, ..., \vec{\alpha}_k \in \mathbb{R}^{n-1}$ denote by $nHT_{\vec{\alpha}_1, ..., \vec{\alpha}_k}$ the $n$-linear operator defined by the product symbol

$$\prod_{j=1}^{k} \text{sgn}(\xi_1 + \alpha_{j1}\xi_1 + ... + \alpha_{j,n-1}\xi_{n-1})$$

(4)

where $\vec{\alpha}_j := (\alpha_{j1}, ..., \alpha_{j,n-1})$ for $j = 1, ..., k$. The following theorem holds.

**Theorem 1.1.** For any $k \geq 1$ and generic numbers $\alpha_1, ..., \alpha_k$, the bilinear operator $2HT_{\alpha_1, ..., \alpha_k}$ satisfies many $L^p$ estimates of Hölder type.

It is a very simple exercise to show that this theorem follows from the $k = 1$ case studied in [8] and [9]. See also [6] for some related results. In other words, for bilinear operators, the $k \geq 1$ situation is as complex as the original $k = 1$ case.

One can then naturally ask if there is an $n$-linear generalization of the above result. This may of course seem hopeless, given the remarks made above. However, we will prove in this paper, that if $k \geq 2$ and $n \geq 4$, the most natural $n$-linear generalization of the above bilinear theorem, is false. More precisely, we will prove

**Theorem 1.2.** Let $k \geq 2$ and $n \geq 4$. Then, for any generic vectors $\vec{\alpha}_1, ..., \vec{\alpha}_k \in \mathbb{R}^{n-1}$, the $n$-linear operator $nHT_{\vec{\alpha}_1, ..., \vec{\alpha}_k}$ does not satisfy any $L^p$ estimates of Hölder type.

This time (and in fact for any $n \geq 3$), the geometry of the symbols (4) becomes more complicated and there do not seem to be any direct connections between the $k = 1$ and $k \geq 2$ cases. In particular, the case $k = 1$ and $n \geq 3$ remains open.

This brings us naturally to the second class of extensions, that we mentioned earlier. We need to set up some notations first. For any $\vec{\beta} \in \mathbb{R}^{n-1}$, denote by $\Gamma_{\vec{\beta}}$ the $(n-1)$ dimensional subspace defined by

$$\Gamma_{\vec{\beta}} := (\xi_1, ..., \xi_{n-1}) \in \mathbb{R}^n : \xi_1 + \beta_1\xi_1 + ... + \beta_{n-1}\xi_{n-1} = 0.$$

Notice that the symbol (2) of $nHT_{\vec{\beta}}$ is singular along $\Gamma_{\vec{\beta}}$, while the symbol (4) of $nHT_{\vec{\alpha}_1, ..., \vec{\alpha}_k}$ is singular along $\Gamma_{\alpha_1} \cup ... \cup \Gamma_{\alpha_k}$. Then, for any $\Gamma \subseteq \mathbb{R}^n$ subspace of arbitrary dimension, denote by $\mathcal{M}_\Gamma(\mathbb{R}^n)$ the class of Marcinkiewicz-Hörmander-Mikhlin symbols which are singular along $\Gamma$. More specifically, $\mathcal{M}_\Gamma(\mathbb{R}^n)$ contains all bounded functions $m(\vec{i})$, which are smooth in the complement of $\Gamma$, and which satisfy

1. In the bilinear case, the vectors $\vec{\alpha}_j$ being one dimensional, can be identified with the numbers $\alpha_j$.

2. Indeed, if $n = 2$, one can first observe that the symbol (4) is constant on various angular regions centered at the origin, and so it is enough to understand bilinear operators whose symbols are the characteristic functions of such angular sets. But (modulo some natural compositions with certain Riesz projections) the study of these can be easily reduced to the study of bilinear operators of type $2HT_{\vec{\beta}}$. The details are left to the reader.

3. However, in this particular case, it has been noticed (first heuristically in [10] and then rigorously in [4]) that the trilinear Hilbert transform cannot map $L^p \times L^p \times L^p$ into $L^p$ for every $1/3 < p < \infty$. See also [2] for another interesting tri-linear counterexample.
for sufficiently many multi-indices $\gamma$. Observe also that if $\Gamma \subseteq \Gamma$ one has the inclusion $\mathcal{M}_f(\mathbb{R}^n) \subseteq \mathcal{M}_f(\mathbb{R}^n)$. Given any $m \in \mathcal{M}_f(\mathbb{R}^n)$ one then denotes by $T_m$ the $n$-linear operator defined by the same formula (1), with the symbol (2) replaced by $m$.

The following general theorem has been proved in [18]. See also [6] for the particular bilinear case.

**Theorem 1.3.** For any non-degenerate subspace $\Gamma \subseteq \mathbb{R}^n$ and $m \in \mathcal{M}_f(\mathbb{R}^n)$, the multi-linear operator $T_m$ satisfies many $L^p$ estimates of Hölder type, as long as $\dim(\Gamma) < \frac{n+1}{2}$.

Notice that the $2HT_{\alpha}$ case corresponds to $n = 2$ and $\dim(\Gamma) = 1$, while $nHT_{\alpha}$ would be covered by the case of subspaces $\Gamma$ of maximal dimension $\dim(\Gamma) = n - 1$.

Given all these results described so far, it is natural (and quite tempting) to believe, that if $\alpha \in \mathcal{M}_f(\mathbb{R}^n)$. Given any $m \in \mathcal{M}_f(\mathbb{R}^n)$, and symbols $m \in \mathcal{M}_f(\mathbb{R}^n)$, as well. In other words, that there exists a non-trivial range of exponents, where Theorem 1.3 can be extended all the way to the maximal dimension $\dim(\Gamma) = n - 1$.

However, it is not difficult to see as a consequence of the previous Theorem 1.2, that this *ideal scenario* cannot be true. We have

**Theorem 1.4.** For any $1 < p_1, \ldots, p_n \leq \infty$ and $0 < p < \infty$ with $1/p_1 + \ldots + 1/p_n = 1/p$, there exist non-degenerate subspaces $\Gamma \subseteq \mathbb{R}^n$ of maximal dimension $n - 1$, and symbols $m \in \mathcal{M}_f(\mathbb{R}^n)$, for which the associated $n$-linear multiplier operators $T_m$ do not map $L^{p_1} \times \ldots \times L^{p_n}$ into $L^p$.

To prove Theorem 1.4 one just has to observe that any $nHT_{\alpha_1,\alpha_2}$ splits quite naturally as

$$nHT_{\alpha_1,\alpha_2} = T_{m_1} + T_{m_2}$$

where $m_1 \in \mathcal{M}_{\Gamma_{\alpha_1}}(\mathbb{R}^n)$ and $m_2 \in \mathcal{M}_{\Gamma_{\alpha_2}}(\mathbb{R}^n)$. Since for generic vectors $\alpha_1$ and $\alpha_2$ the $n$-linear operator $nHT_{\alpha_1,\alpha_2}$ does not satisfy any $L^p$ estimates (cf. Theorem 1.2), it is clearly impossible for both $T_{m_1}$ and $T_{m_2}$ to map $L^{p_1} \times \ldots \times L^{p_n}$ into $L^p$.

Coming now back to Theorem 1.2, its proof will follow from the following weaker, but also more precise, result.

**Proposition 1.5.** For any $k \geq 2$ there exists a positive integer $N(k)$ such that for any $n \geq N(k)$ and generic vectors $\alpha_1, \ldots, \alpha_k \in \mathbb{R}^{n-1}$, the $n$-linear operator $nHT_{\alpha_1,\ldots,\alpha_k}$ does not satisfy any $L^p$ estimates of Hölder type. Moreover, the explicit counterexamples that will be constructed, are irreducible in a certain natural sense.

The preciseness of the proposition lies on this *irreducibility* property of the counterexamples. We will see later on, that given any such irreducible counterexample for $nHT_{\alpha_1,\ldots,\alpha_k}$, it can be naturally localized, rescaled and translated in frequency, so that it automatically becomes a counterexample (which we call *reducible* this time) to the boundedness of any $nHT_{\alpha_1,\ldots,\alpha_k}$ as

---

4The non-degeneracy of $\Gamma$ is understood in the sense of [18]. Without being too specific, let us just say that generic subspaces are non-degenerate. For instance, if $n = 2$, any line is non-degenerate, if it is not one of the coordinate axes, nor the one defined by the equation $\xi + \xi_1 = 0$. 
long as $k' \geq k^\frac{5}{2}$. The constants $N(k)$ above will be quite explicit as we will prove the proposition for $N(k) = \frac{(2k)^k}{(k!)} - 1$. Notice that when $k = 2$, the expression $\frac{(2k)^k}{(k!)} - 1$ is equal to 5, but we will remark later on that Proposition 1.5 remains valid even for $n = 4$. In particular, Theorem 1.2 will follow from the case $k = 2$ and $n \geq 4$ since as we mentioned, the irreducible counterexamples for $nHT_{\vec{a}_1, \vec{a}_2}$ can be transformed into reducible ones for any $nHT_{\vec{a}_1, \vec{a}_2, \ldots, \vec{a}_k}$ when $k \geq 2$. Let us also remark that when both $k$ and $n$ are sufficiently large and $n \geq N(k)$, one obtains quite a few distinct classes of counterexamples for the generic $nHT_{\vec{a}_1, \vec{a}_2}$, since besides the irreducible ones that will be constructed explicitly, there will be various reducible counterexamples coming from the operators having a lower complexity.

It is also interesting to compare all of these negative results with the positive ones in [15], [16] and [17].

The rest of the paper is essentially devoted to the proof of Proposition 1.5. The method we use is a generalization of the arguments from [14] and [19]. See also [5], for some somewhat related ideas.

Acknowledgement: We wish to thank Christoph Thiele for various comments on a preliminary draft of the manuscript. The present work has been partially supported by the NSF.

2. Some heuristical arguments

Before starting the actual proof, we would like to describe a heuristical proof of Proposition 1.5 which will motivate the rigorous argument that will be presented afterwards.

First of all, let us observe that $nHT_{\vec{a}_1, \ldots, \vec{a}_k}(f, f_1, \ldots, f_{n-1})(x)$ admits the alternative kernel representation

$$\frac{(-1)^k}{(i\pi)^k} \cdot \text{p.v.} \int_{\mathbb{R}^k} f(x + t_1 + \ldots + t_k) \prod_{j=1}^{n-1} f_j(x + \alpha_1 jt_1 + \ldots + \alpha_k j t_k) \frac{dt_1}{t_1} \ldots \frac{dt_k}{t_k}. \quad (5)$$

This is a simple consequence of the well known identity $i\pi \text{sgn}(\xi) = \frac{i}{\xi} \hat{f}(\xi)$ applied $k$ times to the symbol (4). Consider now $f(x) = e^{i\#x}$ and $f_j(x) = e^{i\#_j x}$ for $j = 1, \ldots, n-1$ where $\#, \#_1, \ldots, \#_{n-1}$ are real numbers that will be determined later on.

If one plugs in these functions into the formula (5), one formally obtains

$$\text{p.v.} \int_{\mathbb{R}^k} e^{i(\#(x+t_1+\ldots+t_k) + \sum_{j=1}^{n-1} \#_j(x+\alpha_1 j t_1 + \ldots + \alpha_k j t_k)} \frac{dt_1}{t_1} \ldots \frac{dt_k}{t_k}.$$

The new expression

$$\#(x + t_1 + \ldots + t_k)^k + \sum_{j=1}^{n-1} \#_j(x + \alpha_1 j t_1 + \ldots + \alpha_k j t_k)^k \quad (6)$$

should be interpreted as a polynomial in the $k + 1$ variables $x, t_1, \ldots, t_k$ which is homogeneous of degree $k$. An elementary combinatorial computation shows that this expression has precisely $\frac{(2k)^k}{(k!)^2}$ monomials. For reasons that will be clearer a bit later, we would like to choose our numbers $\#, \#_1, \ldots, \#_{n-1}$ in such a way that all the coefficients of these monomials are zero with the

\footnote{We thank Christoph Thiele for pointing out to us this observation.}
exception of the ones corresponding to $x^k$ and $t_1 \cdot \ldots \cdot t_k$. Let us have a look at the coefficient of $t_1$ for instance. It is given by

$$\# + \sum_{j=1}^{n-1} \# j\alpha_1^j$$

and so the fact that it is zero is equivalent to the fact that the $n$-dimensional vector $(\#, \#_1, \ldots, \#_{n-1})$ is orthogonal to $(1, \alpha_1^1, \ldots, \alpha_1^{k-1})$. Since one can argue in a similar way for all the other monomials, our wish becomes equivalent to the fact that $(\#, \#_1, \ldots, \#_{n-1})$ is orthogonal to $(2k)!/k!$ other vectors in $\mathbb{R}^n$. Since $\alpha_1^1, \ldots, \alpha_1^k$ are generic, all these vectors will be linearly independent and the fact that such a vector exists is guaranteed by the condition $n \geq \frac{(2k)!}{k!} - 1$ stated in Proposition 1.5. Furthermore, by a proper dilation, one can also assume that the coefficient of $t_1 \cdot \ldots \cdot t_k$ will be equal to 1.

In particular, for any such a vector $(\#, \#_1, \ldots, \#_{n-1})$ one can write

$$|nHT_{\alpha_1^{\cdot \cdot \cdot}, \alpha_1^k}(f, f_1, \ldots, f_{n-1})(x)| = \frac{1}{\pi^k} \cdot \left| \int_{\mathbb{R}^k} e^{i t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k \right|. \tag{7}$$

On the other hand, the right hand side of (7) can be further calculated as

$$\left| \int_{\mathbb{R}^k} e^{i t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k \right| = \pi \int_{\mathbb{R}^{k-1}} \frac{\text{sgn}(t_1 \cdot \ldots \cdot t_{k-1})}{t_1 \cdot \ldots \cdot t_{k-1}} dt_1 \ldots dt_{k-1} = \pi \left( \int_{\mathbb{R}} \frac{1}{|t|} dt \right)^{k-1}$$

and this means that formally, we have obtained the identity

$$|nHT_{\alpha_1^{\cdot \cdot \cdot}, \alpha_1^k}(f, f_1, \ldots, f_{n-1})(x)| = \frac{1}{\pi^k} \cdot |f(x)f_1(x)\ldots f_{n-1}(x)| \cdot (\int_{\mathbb{R}} \frac{1}{|t|} dt)^{k-1}. \tag{8}$$

Notice that while the moduli of the initial functions are all equal to 1, the right hand side of (8) is infinite. The idea now is to restrict all the functions above to an interval of type $[-N, N]$ and to observe that as long as $x$ belongs to an interval of the same size, one has

$$|nHT_{\alpha_1^{\cdot \cdot \cdot}, \alpha_1^k}(f, f_1, \ldots, f_{n-1})(x)| \geq c (\log N)^{k-1} \tag{9}$$

as $N \to \infty$. Clearly, (9) would imply Proposition 1.5 and from now on the goal is to describe a rigorous proof it \footnote{The functions $f, f_1, \ldots, f_{n-1}$ which appeared in (9) are the old ones restricted smoothly to an interval of type $[-N, N]$.}.

3. Proof of Proposition 1.5

Fix $\alpha_1^1, \ldots, \alpha_1^k$ generic vectors in $\mathbb{R}^{n-1}$. For $N$ large enough, define the function $\chi_N(x)$ to be the characteristic function of the interval $[-N, N]$ and $\overline{\chi}_N(x)$ to be a smooth function supported on $[-N - \epsilon, N + \epsilon]$ and equal to 1 on $[-N, N]$, where $\epsilon > 0$ is a number much smaller than $1/N^k-1$.

Consider real numbers $\#_1, \#_1, \ldots, \#_{n-1}$ chosen to satisfy all the requirements of Section 2. Define the functions $f, f_1, \ldots, f_{n-1}$ by

$$f(x) = \overline{\chi}_N(x)e^{i\#_1}$$
and

$$f_j(x) = \tilde{x}_N(x)e^{\#jx^k}$$

for $1 \leq j \leq n - 1$. We claim that there exist small constants $c$ and $\tilde{c}$ depending on all these parameters with the exception of $N$ so that

$$|nHT_{\tilde{a}_1, \ldots, \tilde{a}_k}(f, f_1, \ldots, f_{n-1})(x)| \geq c(\log N)^{k-1}$$

(10)
as long as $x \in [-\tilde{c}N, \tilde{c}N]$. Clearly, as we pointed out earlier, (10) would immediately imply Proposition 1.5, since it holds for arbitrarily large $N$.

To prove the claim let us first observe that since $f, f_1, \ldots, f_{n-1}$ are smooth and compactly supported, formula (5) can be applied and one has

$$nHT_{\tilde{a}_1, \ldots, \tilde{a}_k}(f, f_1, \ldots, f_{n-1})(x) =$$

$$e^{i(#) + (# \cdots + #_{n-1})x^k} \sum_{\tilde{a}} \int_\mathbb{R}^k \tilde{x}_N(x + t_1 + \cdots + t_k) \prod_{j=1}^{n-1} \tilde{x}_N(x + \alpha_1 j_1 + \cdots + \alpha_k j_k) e^{it_1 \cdots t_k} dt_1 \cdots dt_k.$$

(11)

By splitting $e^{it_1 \cdots t_k}$ as

$$e^{it_1 \cdots t_k} = \cos(t_1 \cdots t_k) + i \sin(t_1 \cdots t_k)$$

and ignoring the harmless factor $e^{i(#) + (# \cdots + #_{n-1})x^k}$, one can decompose the rest of (11) as

$$\frac{(-1)^k}{(i\pi)^k} \int_\mathbb{R}^k \tilde{x}_N(x + t_1 + \cdots + t_k) \prod_{j=1}^{n-1} \tilde{x}_N(x + \alpha_1 j_1 + \cdots + \alpha_k j_k) \cos(t_1 \cdots t_k) \frac{dt_1 \cdots dt_k}{t_1 \cdots t_k}$$

(12)

$$+$$

$$i \frac{(-1)^k}{(i\pi)^k} \int_\mathbb{R}^k \tilde{x}_N(x + t_1 + \cdots + t_k) \prod_{j=1}^{n-1} \tilde{x}_N(x + \alpha_1 j_1 + \cdots + \alpha_k j_k) \sin(t_1 \cdots t_k) \frac{dt_1 \cdots dt_k}{t_1 \cdots t_k}.$$

(13)

It is a good moment now to pause and make a few important remarks regarding the supports of our integrands in (12) and (13). Consider a generic set of the form

$$\{(t_1, \ldots, t_k) \in \mathbb{R}^k : a \leq \beta_1 t_1 + \cdots + \beta_k t_k \leq b\}$$

(14)

with $a < 0 < b$ and $\tilde{\beta} = (\beta_1, \ldots, \beta_k)$ arbitrary. Clearly, this set is a $k$ dimensional strip, containing the origin and lying between the hyperspaces $\beta_1 t_1 + \cdots + \beta_k t_k = a$ and $\beta_1 t_1 + \cdots + \beta_k t_k = b$ which are both perpendicular to the given vector $\tilde{\beta}$. Moreover, the width of this strip is $O(b - a)$.

As a consequence, the support of the integrands in (12) and (13) lies at the intersection of $n$ such $k$ dimensional strips. Since the vectors $\tilde{a}_1, \ldots, \tilde{a}_k$ are generic, if one picks $\tilde{c}$ small enough and $x \in [-\tilde{c}N, \tilde{c}N]$ this intersection will be a bounded domain in $\mathbb{R}^k$ containing the origin and also contained in a large cube of sidelength $O(N)$. Hence, the term (13) is well defined and
this means that the term (12) is well defined as well (being the difference of two well defined expressions).

In particular, from (11), (12) and (13) one can see that

\[ |nHT_{\vec{a}_1, ..., \vec{a}_k}(f, f_1, ..., f_{n-1})(x)| \]

\[ \geq \frac{1}{\pi^k} \left| \int_{\mathbb{R}^k} \chi_N(x + t_1 + ... + t_k) \prod_{j=1}^{n-1} \chi_N(x + \alpha_j t_1 + ... + \alpha_k t_k) \frac{\sin(t_1 \cdot ... \cdot t_k)}{t_1 \cdot ... \cdot t_k} dt_1 ... dt_k \right| \]

(15)

for every \( x \in [-\tilde{c}N, \tilde{c}N] \).

Next, we would like to observe that modulo some harmless error terms, one can replace all the \( \tilde{\chi}_N \) functions in (15) by the corresponding \( \chi_N \). To see this, let us denote the \( n \) linear inner expression in (15) by \( \mathcal{E}(\tilde{\chi}_N, \chi_N, ..., \tilde{\chi}_N)(x) \). One can write

\[ \mathcal{E}(\tilde{\chi}_N, \chi_N, ..., \tilde{\chi}_N)(x) = \mathcal{E}(\chi_N, \chi_N, ..., \chi_N)(x) + \mathcal{E}(\tilde{\chi}_N - \chi_N, \tilde{\chi}_N, ..., \tilde{\chi}_N)(x) \]

and it is not difficult to see that the absolute value of the error term \( \mathcal{E}(\tilde{\chi}_N - \chi_N, \tilde{\chi}_N, ..., \tilde{\chi}_N)(x) \) is at most \( O(1) \), as a consequence of the fact that the function \( \frac{\sin x}{x} \) is bounded and that \( \tilde{\chi}_N - \chi_N \) is supported on a union of two strips of width \( O(1/N^{k-1}) \). Iterating this argument \( n \) times one obtains from (15) that

\[ |nHT_{\vec{a}_1, ..., \vec{a}_k}(f, f_1, ..., f_{n-1})(x)| \]

\[ \geq \frac{1}{\pi^k} \left| \int_{\mathbb{R}^k} \chi_N(x + t_1 + ... + t_k) \prod_{j=1}^{n-1} \chi_N(x + \alpha_j t_1 + ... + \alpha_k t_k) \frac{\sin(t_1 \cdot ... \cdot t_k)}{t_1 \cdot ... \cdot t_k} dt_1 ... dt_k \right| - O(1) \]

(16)

for every \( x \in [-\tilde{c}N, \tilde{c}N] \).

Clearly, the inner term on the right hand side of (16) can be written as

\[ \int_{D_x} \frac{\sin(t_1 \cdot ... \cdot t_k)}{t_1 \cdot ... \cdot t_k} dt_1 ... dt_k \]

(17)

where \( D_x \) is a compact and convex domain in \( \mathbb{R}^k \) containing the origin and having also the property that

\[ [-c_1N, c_1N]^k \subseteq D_x \subseteq [-C_1N, C_1N]^k \]

where \( c_1 \) is small and \( C_1 \) is large and they depend on \( \vec{a}_1, ..., \vec{a}_k \) but are otherwise independent on \( x \in [-\tilde{c}N, \tilde{c}N] \).

Split now (17) as

\[ \int_{D_x} \frac{\sin(t_1 \cdot ... \cdot t_k)}{t_1 \cdot ... \cdot t_k} dt_1 ... dt_k \]
We will prove in the next two sections that the first term in (18) is positive and is bounded from below by \( c \log N \) while the absolute value of the second term in (18) is bounded from above by \( C \log N \).

Combining these two facts with the previous (16) will imply the desired (10).

4. Lower logarithmic bounds

In this section we prove the lower logarithmical bounds for the first term in (18) that have been mentioned at the end of the previous Section 3.

**Proposition 4.1.** For any integer \( k \geq 1 \) there exists a constant \( c(\log N)^{k-1} \) with the property that

\[
\int_{-N}^{N} \cdots \int_{-N}^{N} \frac{\sin(t_1 \cdots t_k)}{t_1 \cdots t_k} dt_1 \cdots dt_k \geq c(\log N)^{k-1}
\]

as long as \( N \) is large enough.

The proof of this Proposition 4.1 is based on the following lemma whose enuntiation requires some additional notations.

If \( f \) is a bounded measurable function defined on the interval \([0, \infty)\) we denote by \( Hf(x) \) the linear operator given by

\[
Hf(x) = \frac{1}{x} \int_{0}^{x} f(u) du
\]

for every \( x \in [0, \infty) \). We will also denote by \( H^l \) the composition of \( H \) with itself \( l \) times (as long as \( l \) is an integer greater or equal than 1) and by \( H^0 \) the identity operator.

**Lemma 4.2.** For any integer \( k \geq 1 \) there exist a small constant \( c_{k-1} \) and a large one \( C_{k-1} \) with the property that

\[
\int_{0}^{t} H^{k-1} F(u) du \geq c_{k-1} (\log t)^{k-1}
\]

for every \( t \geq C_{k-1} \), where \( F(u) := \frac{\sin u}{u} \).

Let us first assume this Lemma 4.2 and show how our previous Proposition 4.1 can be reduced to it.

If \( a \) is any real number different than zero, the function \( s \to \frac{\sin as}{s} \) is an even function and in particular this implies that

\[
\int_{-N}^{N} \frac{\sin as}{s} ds = 2 \int_{0}^{N} \frac{\sin as}{s} ds.
\]

Using this observation several times, one can see that

\[
\int_{-N}^{N} \cdots \int_{-N}^{N} \frac{\sin(t_1 \cdots t_k)}{t_1 \cdots t_k} dt_1 \cdots dt_k = 2^k \int_{0}^{N} \cdots \int_{0}^{N} \frac{\sin(t_1 \cdots t_k)}{t_1 \cdots t_k} dt_1 \cdots dt_k.
\]

(21)
We claim now that the following identity holds

\[
\int_0^N \cdots \int_0^N \frac{\sin(t_1 \cdots t_k)}{t_1 \cdots t_k} dt_1 \cdots dt_k = \int_0^{N^k} H^{k-1} F(u) du.
\]  

(22)

Clearly, if we take this equality for granted then (22), (21) and (20) together imply the desired (19).

For simplicity, we will prove (22) in the particular case \( k = 3 \) and leave the general case to the reader, since it does not require any additional ideas.

One can write

\[
\int_0^N \int_0^N \int_0^N \frac{\sin(t_1 t_2 t_3)}{t_1 t_2 t_3} dt_1 dt_2 dt_3 = \int_0^N \int_0^N \left( \int_0^N \frac{\sin(t_1 t_2 t_3)}{t_3} dt_3 \right) dt_1 dt_2
\]

\[
= \int_0^N \int_0^N \left( \int_0^{N t_1} \frac{\sin x}{x} dx \right) \frac{dt_2}{t_1} \frac{dt_1}{t_1} = \int_0^N \int_0^N \left( \int_0^{N t_1} \frac{\sin x}{x} dx \right) \frac{dy}{y} \frac{dt_1}{t_1}
\]

\[
= \int_0^N \int_0^N \left( \int_0^{N t_1} \frac{\sin x}{x} dx \right) \frac{dy}{y} \frac{dz}{z} = \int_0^N \left( \int_0^N \frac{1}{z} dx \right) \frac{dy}{y} \frac{dz}{z} = \int_0^N H^3 F(z) dz
\]

as desired.

We are left with the proof of Lemma 4.2. We proceed by induction. Clearly, the \( k = 1 \) case is a simple consequence of the fact that \( \int_0^\infty \frac{\sin x}{x} dx = \frac{\pi}{2} \). Suppose now that (20) holds for the parameter \( k - 1 \) and we would like to prove it for \( k \).

One writes

\[
\int_0^N H^k F(u) du = \int_0^N \left( \frac{1}{x} \int_0^x H^{k-1} F(u) du \right) dx
\]

(23)

\[
= \int_0^{C_{k-1}} \cdots + \int_{C_{k-1}}^N \cdots
\]

(24)

The absolute value of the first term in (24) is clearly at most \( C_{k-1} \) given that \( |F(u)| \leq 1 \). Using the induction hypothesis on the other hand, one can estimate the second term in (24) from below by

\[
c_{k-1} \int_{C_{k-1}}^N \frac{1}{x} [(\log x)^{k-1} - (\log C_{k-1})^{k-1}] dx = \frac{c_{k-1}}{k} \int_{C_{k-1}}^N [(\log x)^{k}] dx
\]

\[
= \frac{c_{k-1}}{k} ((\log t)^k - (\log C_{k-1})^{k}).
\]

All of these imply that the left hand side of (23) can be estimated from below by

\[
= \frac{c_{k-1}}{k} ((\log t)^k - (\log C_{k-1})^{k}) - C_{k-1}.
\]

But this expression is at least as big as \( \frac{c_{k-1}}{k} (\log t)^k \) if \( t \) is large enough and this completes the proof of Lemma 4.2 and therefore of Proposition 4.1.
5. Upper logarithmic bounds

Our final goal now is to prove the upper logarithmical bounds for the second term in (18), that have been claimed in Section 3.

**Proposition 5.1.** Let $D$ be a compact and convex domain in $\mathbb{R}^k$ having the property that

$$[-cN, cN]^k \subseteq D \subseteq [-CN, CN]^k$$

where $c$ and $C$ are fixed constants and $N$ is large enough. Then, there exists $\tilde{C}(= \tilde{C}(k))$ so that

$$|\int_{D \setminus [-cN,cN]^k} \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k| \leq \tilde{C}(\log N)^{k-2}.$$  

(25)

We claim that the above Proposition 5.1 follows easily from the following

**Lemma 5.2.** Let $D$ be a compact and convex domain in $\mathbb{R}^k$ having the property that

$$D \subseteq [-N, N]^k.$$

Then, there exists $C (= C(k))$ so that

$$|\int_D \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k| \leq C(\log N)^{k-1}.$$  

(26)

Let us see first why Lemma 5.2 implies Proposition 5.1.

If $\vec{t}^* = (t_1, \ldots, t_k) \in D \setminus [-cN, cN]^k$ then at least for one index $1 \leq i \leq k$ one must have $t_i \notin [-cN, cN]$. But then, this means that $t_i \in [-CN, -cN] \cup [cN, CN]$.

Let us examine now the following two extremal cases.

Suppose first that $t_i \in [-CN, -cN] \cup [cN, CN]$ for every $1 \leq i \leq k$. In this case it is not difficult to see that the integral over that corresponding region is at most

$$\int_{cN}^{CN} \ldots \int_{cN}^{CN} \frac{dt_1}{t_1} \ldots \frac{dt_k}{t_k}$$

which is clearly bounded by a constant independent of $N$.

Assume now that we are in the opposite situation when precisely one index $i$ has the property that $t_i \in [-CN, -cN] \cup [cN, CN]$. By symmetry, we can also assume that that index is 1 and that $t_1 \in [cN, CN]$. In this case, it is also not difficult to see that the integral over the corresponding region can be expressed as

$$\int_{cN}^{CN} \left( \int_{D_{t_1}} \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_2 \ldots dt_k \right) dt_1$$

(27)

where

$$D_{t_1} := \{(t_2, \ldots, t_k) : (t_1, t_2, \ldots, t_k) \in D\}.$$  

It is natural to change variables $t_1^{k-1}t_j = s_j$ for $2 \leq j \leq k$ and rewrite (27) as
\[
\int_{cN}^{CN} \frac{1}{t_1} \left( \int_{\tilde{D}_{t_1}} \frac{\sin(s_2 \cdot \ldots \cdot s_k)}{s_2 \cdot \ldots \cdot s_k} ds_2 \ldots ds_k \right) dt_1 \quad (28)
\]
where \(\tilde{D}_{t_1}\) is also compact and convex and has the property that
\[
\tilde{D}_{t_1} \subseteq [-CN_{t_1}^{1/k-1}, CN_{t_1}^{1/k-1}]^{k-1}.
\]
Using Lemma 5.2 one can then bound (28) easily by \(C(\log N)^{k-2}\) which is of course acceptable by (25).

The general case when an arbitrary number of indices \(i\) satisfy \(t_i \in [-CN, -cN] \cup [cN, CN]\) can be treated similarly and the corresponding upper bound will be of the form \(C(\log N)^l\) for some 0 \(\leq l \leq k - 2\). Since there are only a finite number of such situations, this completes the proof of (25).

We are left with the proof of Lemma 5.2. We proceed as before by induction.

The case \(k = 1\) is obviously true, since \(D\) is now an interval \([a, b]\) and (26) becomes equivalent to
\[
| \int_a^b \frac{\sin x}{x} dx | \leq C.
\]
Let us consider now the general case of (26) assuming (by the induction hypothesis) that all the previous ones are known.

Decompose the inner integral in (26) as
\[
\int_D \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k
\]
\[= \int_{D \cap \{ \| \vec{t} \| \leq 1 \}} \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k + \sum_{d=0}^{\log N} \int_{D \cap \{ \| \vec{t} \| \leq 2^d \}} \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k. \tag{29}
\]
Arguing as before and using the induction hypothesis one can see that
\[
| \int_{D \cap \{ \| \vec{t} \| \leq 2^d \}} \frac{\sin(t_1 \cdot \ldots \cdot t_k)}{t_1 \cdot \ldots \cdot t_k} dt_1 \ldots dt_k | \leq C d^{k-2}. \tag{30}
\]
Finally, using (30) in (29) one obtains the desired (26).

6. FURTHER REMARKS

First of all, as we promised, we would like to explain why Proposition 1.5 holds true even for \(k = 2\) and \(n = 4\). Recall from (5) the kernel representation of \(4HT_{\vec{a}_1,\vec{a}_2}(f, f_1, f_2, f_3)(x)\) as
\[
-\frac{1}{\pi^2} p.v. \int_{\mathbb{R}^2} f(x + t + s) \prod_{j=1}^3 f_j(x + \alpha_{1j}s + \alpha_{2j}t) \frac{dt ds}{t s} \tag{31}
\]
where \(\vec{a}_1 = (\alpha_{11}, \alpha_{12}, \alpha_{13})\) and \(\vec{a}_2 = (\alpha_{21}, \alpha_{22}, \alpha_{23})\) are two generic vectors in \(\mathbb{R}^3\).

\[\text{We use the notation } |\vec{t}|_{\infty} := \max_{1 \leq i \leq k} |t_i|.\]
Consider as before \( f(x) = e^{\#x^2} \) and \( f_j(x) = e^{\#_j x^2} \) for \( j = 1, 2, 3 \) where \( \#, \#,_1, \#,_2, \#,_3 \) are real numbers that will be determined later on. If one formally plugs in these functions into (31), the corresponding expression in (6) becomes a polynomial in the variables \( x, t, s \) which is homogeneous of degree 2. This polynomial has precisely six monomials, namely \( xt, xs, ts, t^2, s^2 \) and \( x^2 \) each of which having its corresponding coefficient. We would like to choose our numbers \( \#, \#,_1, \#,_2, \#,_3 \) so that the coefficients of \( xt, xs \) and \( s^2 \) are all zero. As we discussed earlier in Section 2, this amounts to pick a vector \((\#, \#,_1, \#,_2, \#,_3) \in \mathbb{R}^4 \) orthogonal to three other generic linearly independent 4 dimensional vectors, which is clearly possible. Using this choice, the analogous of (7) becomes

\[
|\text{4HT}_{\vec{\alpha}_1, \vec{\alpha}_2}(f, f_1, f_2, f_3)(x)| = \frac{1}{\pi^2} \int_{\mathbb{R}^2} e^{i\beta \vec{x} \cdot \vec{s}} \frac{ds}{t^2 - s^2} \tag{32}
\]

where \( \alpha, \beta \) are real numbers depending on the previous parameters \( \vec{\alpha}_1, \vec{\alpha}_2 \) and \( \#, \#,_1, \#,_2, \#,_3 \). By construction, one can also assume without loss of generality that \( \alpha > 0 \). As in Section 2 one then observes that the expression on the right hand side of (32) can be calculated further as

\[
\left| \int_{\mathbb{R}^2} e^{i\beta \vec{x} \cdot \vec{s}} \frac{ds}{t^2 - s^2} \right| = \frac{1}{\pi} \int_{\mathbb{R}} \frac{\text{sgn}(t)}{t} e^{i\beta t} dt
\]

\[
= \frac{1}{\pi} \int_{0}^{\infty} e^{i\beta t} dt = \frac{1}{\pi} \int_{0}^{\infty} \cos t \frac{dt}{t} + i\frac{\pi}{2}
\]

and while \( \int_{0}^{\infty} \cos t \frac{dt}{t} \) is bounded, the integral \( \int_{0}^{\infty} \cos t \frac{dt}{t} \) is infinite.

To transform this heuristical argument into a rigorous one, one proceeds as before. The details are left to the reader.

Then, we would like to describe the construction of the reducible counterexamples from the previous irreducible ones, completing in this way the proof of Theorem 1.2. Fix \( k \geq 2 \) and \( n \) such that \( n \geq N(k) \) (here if \( k = 2 \) we should replace \( N(2) \) by 4 since we now know that Proposition 1.5 still holds in this situation). Consider also a generic operator of type \( n\text{HT}_{\vec{\alpha}_1,...,\vec{\alpha}_k} \) where \( k' \geq k \). To construct such a reducible counterexample for it we proceed as follows. At the first step, take the irreducible counterexample given by Proposition 1.5 for the less complex operator \( n\text{HT}_{\vec{\alpha}_1,...,\vec{\alpha}_k} \). By a simple approximation argument one can also assume without loss of generality that the functions which appear in the counterexample are all compactly supported in frequency. Then, by using the dilation invariance of these operators, one can rescale it, and obtain a counterexample whose Fourier transform is supported inside the unit cube of \( \mathbb{R}^n \). After that, using the modulation invariance of the operators, one observes that this unit cube can be translated anywhere along the subspace

\[ \Gamma_{\vec{\alpha}_1} \cap ... \cap \Gamma_{\vec{\alpha}_k} \]

and still remains a counterexample for the boundedness of \( n\text{HT}_{\vec{\alpha}_1,...,\vec{\alpha}_k} \). It is not difficult to observe that one can do this in such a way that the new translated unit cube does not intersect any of the remaining subspaces \( \Gamma_{\vec{\alpha}_{k+1}},...,\Gamma_{\vec{\alpha}_{k'}} \). But then this means that these new functions which correspond to the new rescaled and translated cube, automatically become a counterexample for our original, more complex operator \( n\text{HT}_{\vec{\alpha}_1,...,\vec{\alpha}_k} \).

It is also natural to ask, given the previous Theorem 1.3 and Theorem 1.4, what can be said in the remaining cases, when the dimension of the singularity subspace \( \Gamma \) satisfies
Using an argument similar to the one before, one can prove

**Corollary 6.1.** Let \( n \geq 5 \). For any \( 1 < p_1, \ldots, p_n \leq \infty \) and \( 0 < p < \infty \) with \( 1/p_1 + \cdots + 1/p_n = 1/p \), and for any integer \( k \) satisfying

\[
k > n - \left( \frac{n - 1}{2} \right)^{1/2}
\]

there exist non-degenerate subspaces \( \Gamma \subseteq \mathbb{R}^n \) with \( \dim(\Gamma) = k \) and symbols \( m \in \mathcal{M}_f(\mathbb{R}^n) \), for which the associated \( n \)-linear multiplier operators \( T_m \) do not map \( L^{p_1} \times \cdots \times L^{p_n} \) into \( L^p \).

**Proof** Let \( d \geq 1 \) and denote by \( K(i) = \frac{1}{|i|^{n(d-1)}} \) the first \( d \)-dimensional Riesz kernel. It is a classical well known fact that \( \tilde{K}(\vec{\eta}) = C_d \frac{|\vec{\eta}|^p}{|\vec{\eta}|} \) where \( C_d \) is a constant depending only on the dimension, see for instance [20]. For \( n \geq d \) consider the \( n \)-linear operator defined by the formula

\[
\int_{\mathbb{R}^d} f_1(x - a_1 \cdot i - b_1 \cdot s) \cdots f_n(x - a_n \cdot i - b_n \cdot s) K(i) K(\vec{s}) \, di \, ds
\]

where \( a_j, b_j \) are generic vectors in \( \mathbb{R}^d \) while \( a_1 \cdot i, b_1 \cdot s \) are \( d \) dimensional inner products, for \( 1 \leq j \leq d \). Recall that the functions \( f_1, \ldots, f_n \) are all defined on the real line.

Alternatively, as before, one can rewrite (33) as

\[
\int_{\mathbb{R}^n} \tilde{K}(A\vec{\eta}) \tilde{K}(B\vec{\eta}) f_1(\eta_1) \cdots f_n(\eta_n) e^{2\pi i \sum \eta_j} \, d\eta_1 \cdots d\eta_n
\]

where \( A = [a_1 \ldots a_n] \) and \( B = [b_1 \ldots b_n] \) are both matrices having \( d \) lines and \( n \) columns and they define linear maps from \( \mathbb{R}^n \) to \( \mathbb{R}^d \). Since \( \tilde{K} \) is singular only at the origin, it is clear that the symbol of our operator \( i\vec{\eta} \rightarrow \tilde{K}(A\vec{\eta}) \tilde{K}(B\vec{\eta}) \) will be singular along \( \text{Ker}(A) \cup \text{Ker}(B) \) and for generic matrices \( A \) and \( B \) both of these subspaces will have dimension \( n - d \). Consider now \( f_j(x) = e^{2\pi i \eta_j x^2} \) for \( 1 \leq j \leq n \) where the real numbers \( \left( \# \right)_{j=1}^n \) will be determined later. If one formally plugs in these functions into the formula (33), the exponent of the new complex exponential is the quadratic expression

\[
\#_1(x - a_1 \cdot i - b_1 \cdot s)^2 + \cdots + \#_n(x - a_n \cdot i - b_n \cdot s)^2
\]

depending on the variables \( x, t_1, \ldots, t_d, s_1, \ldots, s_d \). If one expands (34), one can see by an elementary calculation, that it contains \( 2d^2 + 2d + 1 \) quadratic monomials. We choose now the vector \( \# = (\#_1, \ldots, \#_n) \) in such a way that all the coefficients of these monomials vanish, with the exception of the coefficients corresponding to \( x^2, t_1 s_1, \ldots, t_d s_d \). As we have seen before, this is equivalent to the fact that \( \# \) is orthogonal to \( 2d^2 + d \) other linearly independent \( n \) dimensional vectors, which is clearly possible as long as \( n \geq 2d^2 + d + 1 \). From this we deduce that \( d < \left( \frac{n-1}{2} \right)^{1/2} \) which in particular implies

\[
\dim(\text{Ker}(A)) = \dim(\text{Ker}(B)) > n - \left( \frac{n - 1}{2} \right)^{1/2}.
\]
On the other hand, it is not difficult to see that the absolute value of the corresponding expression in (33), is comparable to the divergent integral

$$\int_{\mathbb{R}^d} \frac{t^2}{|t|^{d+2}} d\tilde{t}$$

a fact that can be used, also as before, to show that the $n$-linear operator (33) does not satisfy any $L^p$ estimates. Since this operator can be also naturally decomposed as $T_{m_1} + T_{m_2}$ with $m_1 \in \mathcal{M}_{\text{Ker}(A)}(\mathbb{R}^n)$ and $m_1 \in \mathcal{M}_{\text{Ker}(B)}(\mathbb{R}^n)$, it is clearly impossible for both $T_{m_1}$ and $T_{m_2}$ to satisfy the required particular estimates of Corollary 6.1.

Another interesting consequence is the following. On the one hand, let us observe that Theorem 1.2 holds not only for the operators $nHT_{\tilde{\alpha}_1, \ldots, \tilde{\alpha}_k}$, but also for operators whose symbols are given by products of type (4), where “$\text{sgn}$” is replaced by “$1_{\mathbb{R}^n}$” the characteristic function of the set of positive real numbers. Indeed, this change corresponds to replacing the previous kernels “$\frac{1}{t}$” by “$\frac{1}{t} + \delta_0(t)$” (where $\delta_0(t)$ is the Dirac delta distribution centered at the origin) and it is not difficult to see that this does not change the outcome of the previous arguments. In particular, when $k = 2$, this implies that $n$-linear operators with symbols such as the ones described on the right hand side of Figure 1, do not satisfy any $L^p$ estimates of Hölder type $^8$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{Good (?) and bad symbols}
\end{figure}

On the other hand, if the $n$-linear Hilbert transforms were to satisfy some $L^p$ estimates, then by taking the difference between two generic ones, one would obtain the same $L^p$ estimates for $n$-linear operators given by symbols such as the ones described on the left hand (this time) side of Figure 1.

Let us end with a few remarks on the previous identity (3). First of all, it can be suggestively rewritten as

$$\int_{[0,1]^{p-1}} nHT_{\tilde{\alpha}}(f, a, \ldots, a)(x) d\tilde{\alpha} = p.v. \int_{\mathbb{R}} \left( \frac{\Delta_t A(x)}{t} \right)^{n-1} f(x + t) \frac{dt}{t} \quad (36)$$

where in general $\Delta_t g(x) := g(x + t) - g(x)$ is the finite difference of the function $g$ at scale $t$. In [12] the following generalization of it has been noticed

$$\int_{[0,1]^{p-1}} \ldots \int_{[0,1]^{p-1}} nHT_{\tilde{\alpha}_1, \ldots, \tilde{\alpha}_k}(f, a, \ldots, a)(x) d\tilde{\alpha}_1 \ldots d\tilde{\alpha}_k$$

$^8$The diagram should be understood in $\mathbb{R}^n$. The two lines represent two generic hyperspaces $\Gamma_1$ and $\Gamma_2$. 
\[ \int_{\mathbb{R}^d} \left( \frac{\Delta_{t_1} \circ ... \circ \Delta_{t_k} f(x)}{t_1 ... t_k} \right)^{n-1} f(x + t_1 + ... + t_k) \frac{dt_1}{t_1} ... \frac{dt_k}{t_k} \]

where this time \(A^{(k)} = a\). It is interesting to mention that the linear operators on the right hand side of (37) are bounded on \(L^p\) for every \(1 < p < \infty\) as long as \(A^{(k)} \in L^\infty\).

These operators appeared naturally in [12] as part of a generalization of Calderón’s theory to classes of functions having arbitrary polynomial growth. For more details, the reader is referred to the recent sequel of the author [11], [12] and [13].
