Abstract: Three species of nematodes from the Camallanidae that are known to infect Xenopus laevis Daudin (Anura: Pipidae) were collected from several localities across South Africa. New data on morphology, partial 28S and cox1 genes, infection levels and distribution are presented herein. The most common species, Batrachocamallanus slomei Southwell et Kirshner, 1937, from the stomach and less often oesophagus, was found in eight localities. Camallanus kaapstaadi Southwell et Kirshner, 1937, also from the oesophagus, was found in two localities and C. xenopodis Jackson et Tinsley, 1995, from the intestine, at a single locality. New localities for both C. kaapstaadi and C. xenopodis provide a geographical range extension. Males of C. xenopodis are described for the first time herein. The existence of a left spicule in the males of both the species of Camallanus Railliet and Henry, 1915 is confirmed and measurements are provided. Although C. xenopodis is distinguished from C. mazabukae Kung, 1948 in the present study, we suggest greater sampling effort in other African amphibians to confirm the species status of the latter taxon. Finally, the new molecular data showed distant relationships between collected species of Camallanus and species parasitising fish and freshwater turtles.

Keywords: African clawed frog, parasites, Nematoda, Camallanidae, Camallanus, C. kaapstaadi, C. xenopodis, Batrachocamallanus, B. slomei, Procamallanus

Over 25 parasite genera from seven invertebrate groups have been reported to be associated with the African clawed frog Xenopus laevis Daudin (Anura: Pipidae) in its native southern African range (Tinsley 1996). Some of these parasites have followed their invasive hosts out of Africa to North America, as well as to Europe (Lafferty and Page 1997, Kuperman et al. 2004). One group of parasites that, to date, has not been reported from feral populations of X. laevis is the nematodes of the family Camallanidae that primarily parasitise marine and freshwater fish and less often amphibians, turtles and snakes (Stromberg and Crites 1974).

In clawed frogs across the southern African subcontinent, representatives of camallanids are widespread – Kenya, Nigeria, Rwanda, Uganda and Zimbabwe (Thurston 1970, Avery 1971, Tinsley et al. 1979). Specifically, three species of camallanids are associated with X. laevis in South Africa: Camallanus kaapstaadi Southwell et Kirshner, 1937, C. xenopodis Jackson et Tinsley, 1995 and Batrachocamallanus slomei (Southwell et Kirshner, 1937).

Camallanus kaapstaadi was described from X. laevis from Cape Town (South Africa) (Southwell and Kirshner 1937). Subsequently, it was identified from clawed frogs (X. laevis and other Xenopus spp.) from Cameroon, Ghana, Kenya, Nigeria, Rwanda, northern and south-eastern parts of South Africa (previously known as Transvaal and Transkei), Sudan, Tanzania, Togo, Uganda and Zimbabwe (Avery 1971, Jackson and Tinsley 1995a).

Furthermore, the junior synonym of C. kaapstaadi, C. johni Yeh, 1960, was described from Tanzania (Yeh 1960) and later also reported from Zimbabwe, Uganda and Nigeria under this name (Thurston 1970). In the meantime, Tinsley et al. (1979) recorded the presence of a species of Camallanus Railliet and Henry, 1915 in X. wittei Tinsley, Kobel et Fischberg from central Africa, which was later identified as C. kaapstaadi (Jackson and Tinsley 1995a). Therefore, C. kaapstaadi can be regarded as a widespread parasite of clawed frogs across Africa.

The second camallanid from X. laevis, C. xenopodis, was described based only on six female specimens from...
the Cape (South Africa) and one female specimen which was recovered in Kenya from *X. borealis* Parker (Jackson and Tinsley 1995a). Neither of these species has been recorded since.

The third species, *B. slomei*, was also described as *Procamallanus slomei* Southwell and Kirschner, 1937 from *X. laevis* from the Cape (South Africa) (Southwell and Kirschner 1937) and was formally recorded for the first time since its original description as *B. slomei* from clawed frog hosts in South Africa and Zaire (Jackson and Tinsley 1995b). Jackson and Tinsley (1995b) also synonymised *Procamallanus brevis* Kung, 1948 from *X. laevis* in South Africa (Kung 1948) with *B. slomei* and reidentified a *Spirococcamallanus xenopodis* Southwell and Kirschner, 1937 in a clawed frog from Kenya (Thurston 1970) as belonging to the same species.

The redescription of *B. slomei* as a member of the genus *Batrachocamallanus* Jackson et Tinsley, 1995 is not without controversy (Jackson and Tinsley 1995b). The genus *Batrachocamallanus* was erected specifically for the four species of *Procamallanus* Baylis, 1923 parasitising African amphibians, based upon the large number of mucrons (more than five) on the female tail, relatively smaller body size and the almost identical cephalic morphology, male caudal structures and female reproductive system that differentiated the amphibian parasites from all other species of *Procamallanus* (see Jackson and Tinsley 1995b).

Moravec et al. (2006) considered differences in female mucron number and affinity to an amphibian host as not sufficient generic characters and advocated for the reduction of *Batrachocamallanus* to a junior synonym of *Procamallanus*. This decision was based on the description of *Procamallanus pacificus* Moravec, Justine, Würtz, Taraschewski et Sasal, 2006 from Pacific eels (*Anguilla* sp.) (Actinopterygii: Anguillidae) bearing four to nine mucrons on the female tail (Moravec et al. 2006) and the discovery of *B. sihuranae* Jackson et Tinsley, 1995, previously described from *Xenopus tropicalis* Gray (Anura: Pipidae), from the polypterid fish *Erpetoichthys calabaricus* Smith (Actinopterygii: Polypteridae) (Řehulková et al. 2005).

However, only one immature female specimen of *B. sihuranae* was recovered from the polypterid fish, which was a specimen imported for the pet trade, leading the authors to believe this to be an accidental infection (Řehulková et al. 2005). Moreover, the small processes on the tail of female *P. pacificus* are 6 µm to 9 µm long whereas the mucrons of *Batrachocamallanus* spp. vary from 10 µm to 15 µm (Jackson and Tinsley 1995b, Moravec et al. 2006). Therefore, the mucrons of *P. pacificus* might not represent the same structures as in *Batrachocamallanus* and probably cannot be used for suppression of the genus. Taken as a whole, these factors cast doubt on the validity of the suppression of *Batrachocamallanus*, leading us to assign our specimens to *B. slomei*.

It is clear that information on the camallanids from *X. laevis* are in need of augmentation, especially on the molecular front. The present studies of three species of camallanids collected from *X. laevis* in different regions of South Africa add information on the infection level, localities, morphology and molecular data of the 28S rRNA and cox1 genes.

**MATERIALS AND METHODS**

In total, 97 *Xenopus laevis* were collected in chicken liver baited funnel traps from eight localities across the northern regions of South Africa during November of 2016 and March to May of 2017 and from three localities in the south-western regions during June and July of 2017 (Table 1).

The hosts were anaesthetised in 6% ethyl-3-aminobenzoate methanesulfonate (MS222) (Sigma-Aldrich Co., St. Louis, Missouri, USA) and subsequently euthanised through severing the spine and destroying the brain, according to internationally accepted standard operating procedures. During the total dissection, the alimentary canal was removed and opened in 0.6% amphibian saline. After removal from the oesophagus, stomach and intestine, nematodes were washed in saline, fixed in 70% hot ethanol and subsequently stored in 70% ethanol.

Prior to microscopic examination, the nematodes were cleared in lactophenol. The morphology of the nematodes was studied and photomicrographs were taken using a Nikon E800 and Nikon ECLIPSE Ni compound microscopes. Apical and transverse sections were prepared manually.

In total, 601 specimens of *B. slomei*, 39 of *C. kaapstaadi* and 53 of *C. xenopodis* were studied of which 50 (20 males and 30 females), 18 (nine males and nine females) and 28 (four males and 24 females), respectively, were measured. All measurements in the text are given in micrometres, unless otherwise indicated and presented as ranges followed by mean values in parentheses. The representative sample (30 specimens) expressed as mean with standard deviation (SD).

For the molecular studies, the middle fragments of males were used, while taxonomically important anterior and posterior parts were reserved for the morphological identification of species. DNA was extracted using the KAPA Express Extraction Kit (KAPA) and the DNA was sequenced using the primer pair ‘LCO1490’ (5’-GGTCAACAAAT-CATAAAGATATTGG-3’) and ‘HCO2198’ (5’-TAAACCTTCAG-GGTGACCCAAAAATTAACTC-3’). The thermocycling profile was: 3 min denaturation at 94°C, 10 cycles of 94°C for 30 s, 45°C for 30 s, 72°C for 60 s and 40 cycles of 94°C for 30 s, 51°C for 60 s, 72°C for 60 s and amplification for 72°C for 10 min for extension.

The 28S amplicons were amplified using forward primer ‘LSU5’ (5’-TAGGTGAGGCCGCTGAAYTTAGCA-3’) and reverse primer ‘n900r’ (5’-GGTTCGATCATGCTTTCGCC-3’). The thermocycling profile was as follows: 5 min denaturation at 95°C; 40 cycles of 30 s at 95°C, 30 s at 55°C, 2 min at 72°C for amplification; and a final 7 min extension at 72°C. Sequences were obtained using BigDye® Terminator v3.1 Cycle Sequencing on an ABI3500XL sequencer. DNA products were sequenced in both directions using the pairs of PCR primers; for the nuclear genes the following additional primers were used: internal primers, ‘300F’ (5’-CAATGTCGGAGGGAAGATTGG-3’) and ‘ECD2’ (5’-CTTGGTCCTGGTTCACAGGCGG-3’). Contiguous sequences were assembled, edited using Geneious 9.0 software and submitted to GenBank.

For the phylogenetic analysis, Bayesian inference in the MrBayes program (V. 3.2.2) was used. Prior to analysis, sequences were
Table 1. Geographic origin, habitat and level of infection of three nematodes of 97 Xenopus laevis Daudin from 11 localities in South Africa. Mean intensity of infection is given with median intensity in square brackets and minimum and maximum values in parentheses. Fields with 'n/a' refer to absent infection level values due to absence of nematodes in the digestive tract.

General description. Body small, usually coiled ventrally, comparatively thick, with maximum width at level of anterior third. Cuticle with prominent transverse striations. Apical (Fig. 1B): oral opening rounded, surrounded by six flat elevations (two larger lateral and four submedian); six labial papillae; four cephalic papillae; two amphids. Buccal capsule with well sclerotised walls, somewhat longer than wide with conspicuous basal ring and without internal ridges (Fig. 1A,C). Muscular oesophagus opening surrounded with three tooth-like projections of basal ring (Fig. 1C). Muscular oesophagus club-shaped with elongated posterior bulb. Glandular oesophagus somewhat longer than muscular oesophagus, almost cylindrical but slightly widened posteriorly. Nerve ring encircling muscular oesophagus at level of its proximal third. Excretory pore opening at level of muscular oesophageal mid-length. Minute papilliform deirids situated at level of excretory pore. Intestine straight, narrow. Rectum straight, with thin walls (Fig. 1E). Tail tapering with numerous mucrons in females (Fig. 1E) and rounded tip in males (Fig. 1D).

Male (morphometry based on 20 specimens). Body 1.94–2.80 mm (2.32 mm) long, 96–157 (120) maximum width. Buccal capsule 93–112 (102) long, including basal ring 7–14 (11) long, 53–75 (61) wide with maximum width 67–94 (76) at mid-length and minimum width 26–53 (35) at anterior extremity. Minimum and maximum thickness of buccal capsule walls close to oral opening 2–4 (2.5) and to basal ring 4–10 (6). Muscular oesophagus 188–282 (235) long, 9–12% (10%) of body length; 33–56 (43), 33–43 (38) and 60–97 (75) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 208–366 (301) long, 10–15% (13%) of body length; 46–81 (58), 32–68 (52) and 32–88 (65) wide at anterior, mid-length and posterior level, respectively. Nerve ring at 153–200 (177) from anterior extremity. Excretory pore and deirids situated at 127–280 (217), 6–11% (9%) of body length and 213–260 (238), 9–12% (10%) of body length from anterior extremity, respectively. Posterior end coiled ventrally, provided
with well-developed vesicular caudal alae supported by pedunculate papillae near mid-length. Posterior part of alae slightly elevated and joined on ventral surface forming pseudosucker. Tail conical with rounded tip, 37–50 (42) long. Caudal region possessing pedunculate papillae (Fig. 1D): eight pairs of precloacal; one pair of adcloacal and three pairs of postcloacal. Three pairs of sessile papillae surrounding cloaca (one slightly anterior to and two somewhat posterior to). Spicules unequal, simple-shaped with sharply pointed distal ends. Right spicule clearly visible, 90–115 (101) long; left one less sclerotised, 15–37 (25) long. Gubernaculum absent.

Female (morphometry based on 30 specimens). Body 1.67–3.51 mm (2.87 mm ± 0.54 mm) long, 163–284 (225 ± 39) maximum width. Buccal capsule 105–138 (122 ± 9) long, including basal ring 10–17 (14 ± 2) long, 63–90 (76 ± 7) wide; maximum width 86–113 (103 ± 6) at mid-length and minimum width 34–71 (48 ± 9) at anterior extremity. Minimum and maximum thickness of buccal capsule walls close to oral opening 2–6 (3 ± 1) and to basal ring 4–11 (8 ± 2). Muscular oesophagus 242–337 (288 ± 22) long, 8–17% (10% ± 2%) of body length; 38–72 (51 ± 8), 40–60 (49 ± 5) and 68–116 (95 ± 12) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 248–526 (369 ± 62) long, 9–18% (13% ± 2%) of body length; 48–78 (65 ± 8), 38–76 (60 ± 9) and 57–108 (78 ± 15) wide at anterior, mid-length and posterior level, respectively. Nerve ring at 161–221 (206 ± 14) from anterior extremity. Excretery...
pore and deirids situated at 184–326 (246 ± 27), 7–13%, (9% ± 2%) of body length, and 196–298 (242 ± 27), 6–11% (9% ± 1%) of body length, from anterior extremity, respectively. Vulva (Fig. 1F) situated near body mid-length at 1.13–1.94 mm (1.61 mm ± 0.27 mm) from anterior extremity; 42–60% (54% ± 3%) of body length. Tail 34–59 (48 ± 6) long with five to seven mucrons at its tip (Fig. 1E).

**Camallanus kaapstaadi** Southwell et Kirshner, 1937

**Host:** *Xenopus laevis* Daudin (Amphibia: Anura: Pipidae).

**Localities:** Mpumalanga, Western Cape (see Table 1).

**Site of infection:** Oesophagus, stomach.

**Representative DNA sequences:** MG948461 (*cox1*), MG947391 (28S).

**General description.** Medium-sized worms, coiled dorsally, body comparatively thick with maximum width at anterior third level. Cuticle with prominent transverse striations along whole body, except at buccal capsule. Apical: oral opening transversely slit; four conspicuous submedian cephalic papillae. Buccal capsule consisting of two valves each supported with numerous primarily completed ridges (Fig. 2A,B). Four sclerotised plates situated on external surface of valves near their anterior margin. Thick sclerotised basal ring present at buccal capsule base. Buccal capsule valves supported by two prominent tridents on

**Fig. 2.** *Camallanus kaapstaadi* Southwell et Kirshner, 1937 from *Xenopus laevis* Daudin, photomicrographs. A – anterior end, male, lateral view; B – dorsal trident, male, lateral view; C – ventral trident, male, lateral view; D – posterior end, female, lateral view; E – part of female genital system at vulva level, lateral view; F – left and right spicules, lateral view; G – caudal end, male, ventral view.
dorsal and ventral side (Fig. 2B,C). Each trident consisted of three posteriorly directed prongs. Central prongs somewhat longer than sublateral ones. Tridents usually unequal, beginning at level of buccal capsule mid-length and ending slightly posterior to level of basal ring. Muscular oesophagus club-shaped with elongated posterior bulb. Glandular oesophagus almost equal in length to muscular oesophagus, cylindrical to ¾ length with slightly widened posterior quarter. Nerve ring encircling muscular oesophagus at level of its anterior quarter. Excretory pore opening on ventral side somewhat posterior to nerve ring level. Deirids minute, papilliform, situated at level of posterior third of muscular oesophagus. Intestine and rectum straight, narrow. Tail tapering.

**Male** (morphometry based on nine specimens). Body 2.66–3.28 mm (3.04 mm) long, 102–171 (149) wide. Buccal capsule valves 62–100 (83) long, 65–118 (106) wide, supported by 16–31 (26) ridges, of which 7–10 (8) incomplete. Basal ring 7–14 (10) long, 52–89 (77) wide. Dorsal trident 51–72 (66) long and 15–23 (19) wide in lateral projection, ventral one 48–67 (58) long and 17–23 (20) wide. Muscular oesophagus 261–381 (338.4) long, 9.8–12.3% (11.1%) of body length; 53–63 (58.8), 46–61 (53.9) and 58–95 (86.1) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 275–461 (368.5) long, 9.1–14.9% (12.1%) of body length; 35–96 (61.5), 44–82 (59.5) and 42–76 (59.9) wide at anterior, mid-length and posterior level, respectively. Nerve ring, excretory pore and deirids (distance to deirids measured in three specimens) at 150–246 (182.9), 191–277 (216.1) and 226–257 (241.7) from anterior extremity, respectively. Caudal alae narrow, ventrolateral, supported by papillae: six pairs of pre-cloacal pedunculated papillae (Fig. 2G); one pair of pedunculated papillae at cloaca level; five pairs of post-cloacal pedunculated papillae (three prominent pairs somewhat posterior to cloaca and two pairs of small papillae close to tail end). Additionally, two pairs of sessile ad-cloacal papillae situated slightly anterior and posterior to cloaca. Spicules unequal, simple-shaped with sharpened tips (Fig. 2F). Right spicule prominent, 287–468 (422.5) long; left one less sclerotised (measured in three specimens), 198–220 (211.7) long. Tail conical with two minute spines on tip (Fig. 1G), 74–104 (91.5) long, 2.5–3.2% (3.0%) of body length.

**Female** (morphometry based on nine specimens). Generally larger than males. Body 2.80–5.13 mm (3.62 mm) long, 201–293 (242) wide. Buccal capsule valves 95–149 (116) long, 81–174 (147) wide, supported by 31–38 (34) ridges, of which 7–10 (9) incomplete. Basal ring 9–20 (13) long, 71–125 (106) wide. Dorsal trident 72–102 (86) long and 21–29 (25) wide in lateral projection, ventral one 63–88 (76) long and 14–35 (24) wide. Muscular oesophagus 373–451 (414) long, 7.14% (12%) of body length; 58–87 (76), 46–79 (69) and 97–140 (123) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 313–531 (390) long, 6–15% (11%) of body length; 50–91 (72), 49–91 (66) and 52–105 (79) wide at anterior, mid-length and posterior level, respectively. Nerve ring, excretory pore and deirids (distance to deirids measured in five specimens) at 183–242 (220), 229–307 (266) and 261–375 (306) from anterior extremity, respectively. Vulva post-equatorial, opening posterior to distinct projection of body wall at 1.67–2.64 mm (2.16 mm) from anterior extremity (Fig. 2E), 51–63% (60%) of body length. Tail tapering 124–179 (143) long, 3–5% (4%) of body length, bearing three mucrons 5–11 (8) long at its tip (Fig. 2D).

**Camallanus xenopodis** Jackson et Tinsley, 1995

**Host:** *Xenopus laevis* Daudin (Amphibia: Anura: Pipidae). **Locality:** Western Cape (see Table 1). **Site of infection:** Intestine. **Representative DNA sequences:** MG948462 (cox1), MG947389 (28S).

**General description.** Medium-sized worms, coiled dorsally, body comparatively thick with maximum width at anterior third level. Cuticle with transverse striations clearly visible from level of basal ring to posterior extremity. Apical: oral opening transversely slit; four conspicuous submedian cephalic papillae. Buccal capsule comparatively small, consisting of two valves, supported by longitudinal ridges, with four thin plates on anterior margin, sclerotised basal ring at base and two tridents (Figs. 3B–D, 4A–C). Tridents prominent, equal in shape, almost equal in size, with central prongs somewhat longer than sublateral ones (Figs. 3C,D, 4B,C). Tridents beginning at level of buccal capsule mid-length, ending somewhat posterior to basal ring. Muscular oesophagus club-shaped with elongated posterior bulb. Glandular oesophagus almost same length as muscular oesophagus, cylindrical along almost entire length with slightly widened or narrowed posterior quarter. Position of nerve ring varying within level of muscular oesophagus anterior third. Excretory pore opening on ventral side somewhat posterior to nerve ring level. Deirids minute, papilliform, situated at level of muscular oesophageal mid-length. Intestine and rectum straight, narrow. Tail tapering.

**Male** (description based on four specimens). Body 2.88–3.30 mm (3.04 mm) long, 113–127 (118) wide (Fig. 3A). Buccal capsule valves 62–70 (66) long, 72–82 (77) wide, supported by 18–22 (20) ridges, of which 4–6 (5) incomplete. Basal ring 5–11 (9) long, 50–55 (53) wide. Dorsal trident (Figs. 3C, 4B) 57–69 (62) long and 10–18 (15) wide at lateral projection, ventral one (Figs. 3D, 4C) 51–63 (59) long and 9–16 (13) wide. Muscular oesophagus 257–305 (284) long, 9–11% (9%) of body length; 43–51 (45.5), 38–45 (41) and 59–74 (65) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 209–313 (271) long, 7–11% (9%) of body length; 39–61 (47), 38–58 (49) and 34–73 (53) wide at anterior, mid-length and posterior level, respectively. Nerve ring, excretory pore and deirids (distance to deirids measured in one specimen) at 140–159 (149), 184–211 (198) and 213 from anterior extremity, respectively.
Caudal alae comparatively narrow, ventrolateral, supported by papillae (Figs. 3F, 4F): six pairs of pre-cloacal pedunculated papillae; one pair of pedunculated papillae at cloaca level; four pairs of post-cloacal pedunculated papillae (two prominent pairs somewhat posterior to cloaca, one pair at tail mid-length and one pair of small papillae close to tail end). Two pairs of sessile adcloacal papillae situated slightly anterior and posterior to cloaca. Spicules unequal. Right spicule (Figs. 3E, 4E) 323–356 (335) long with short conical process directed dorsally at its tip. Left spicule shorter, 96–98 long (measured in two specimens), poorly sclerotised, with simple-shaped sharpened tip (Fig. 4D). Tail tapering with smoothly rounded tip (Figs. 3F, 4F).

**Female** (description based on 24 specimens). Generally larger than males. Body 3.33–5.13 mm (4.20 mm) long, 136–241 (177) wide. Buccal capsule valves 73–85 (81) long, 73–104 (93) wide, supported by 14–22 (18) ridges, of which 3–7 (5) incomplete. Basal ring 8–14 (11) long, 62–74 (67) wide. Dorsal trident 53–93 (76) long and 11–25 (16) wide at lateral projection, ventral one 61–85 (75) long and 12–20 (16) wide.

Muscular oesophagus 326–433 (353) long, 7–12% (9%) of body length; 48–68 (58), 39–59 (51) and 76–104 (89) wide at anterior, mid-length and bulb level, respectively. Glandular oesophagus 310–455 (374) long, 7–11% (9%) of body length; 42–84 (61), 51–111 (71) and 48–85 (66)
wide at anterior, mid-length and posterior level, respectively. Nerve ring, excretory pore and deirids (distance to deirids measured in eight specimens) at 171–212 (186), 210–256 (228) and 180–291 (247) from anterior extremity, respectively.

Vulva opening posterior to distinct projection of body wall almost at level of mid-body at 1.72–2.59 mm (2.14 mm) from anterior extremity (Fig. 3G), 47–54% (51%) of body length. Tail tapering 94–165 (129) long, 3–4% (3%) of body length, bearing three mucrons 5–7 (6) long at its tip (Fig. 3H).

Molecular analysis

For all three species, partial 28S gene and cox1 fragments were sequenced. Only for five species of Camallanus from Australian freshwater turtles partial sequences of the 28S subunit are available in GenBank. These species were used for the phylogenetic analysis and Serpinema octorugatum (Baylis, 1933) was used as outgroup since it represents the most related genus to Camallanus (see Kuzmin et al. 2011). The resulting tree (Fig. 5) confirmed the interrelationships among C. tuckeri Kuzmin, Tkach, Snyder et Maier, 2009, C. sprenti Kuzmin, Tkach, Snyder et Bell, 2011, C. waelhreow Rigby, Sharma, Hechinger, Platt et Weaver 2008, C. nithoggi Rigby, Sharma, Hechinger, Platt et Weaver 2008 and C. beveridgei Kuzmin, Tkach, Snyder et Bell, 2011 showed by Kuzmin et al. (2011) and showed their distant relations to C. kaapstaadi and C. xenopodis.

The cox1 sequences are available for only two species of Camallanus, namely C. cotti Fujita, 1927 and C. hypophthalmichthys Dogel et Akhmerov, 1959, originally described from fishes in the Eastern Palaearctic (Moravec et al. 2004, Moravec and Justine 2006). For this analysis, Spirocamallanus istiblenni Noble, 1966 was used as outgroup. Phylogenetic tree topology showed distant relation-

**DISCUSSION**

During the course of the present study, all three species of camallanid nematodes that have previously been reported from *Xenopus laevis* were found. The most common nematode encountered in the present study was *B. slomei*, reported from all but three localities with prevalence ranging from 7% to 100% (Table 1). Conversely, the other two species were found only in two localities. Both *C. kaapstaadi* and
*C. xenopodis* were only found at one locality, namely a series of dams in a mountain stream near Dullstroom (Mpumalanga Province, northern region of South Africa) and only *C. kaapstaadi* was found at one locality in Cape Town (Western Province). The higher level of nematode diversity at this specific locality where both *Camallanus* species occur, corresponds with the higher numbers of other parasites (cestodes, monogeneans, digeneans and parasitic arthropods) also found here in comparison to other localities (unpubl. data). In our opinion, this can be explained by the pristine condition of the habitat and lack of human disturbance allowing a better environment for parasite circulation.

Our results confirm the presence of *C. kaapstaadi* in South Africa, in the light of the fact that many previous records are from more northern regions in Africa such as Cameroon, Ghana, Kenya, Nigeria, Rwanda, Sudan, Tanzania, Togo, Uganda and Zimbabwe (Yeh 1960, Thurston 1970, Avery 1971, Tinsley et al. 1979, Jackson and Tinsley 1995a). We found *C. xenopodis* in the north of South Africa, indicating a less disjunct distribution than the two previous records from the Cape and Kenya suggest (Jackson and Tinsley 1995a). We hypothesise that species of *Camallanus* in clawed frogs are more widespread than previous studies imply, which will be outlined in further studies.

*Batrachocamallanus slomei* is found primarily in the stomach, but also in some cases in the oesophagus. Our findings suggest no correlation between the number of nematodes in the stomach and their presence in the oesophagus of the same frog. For example, the frog with the highest infection of *B. slomei* harboured 36 nematodes in the stomach and one nematode in the oesophagus, whereas another frog harboured 15 in the stomach and 17 in the oesophagus. Only one specimen of *C. kaapstaadi* was found in the stomach while all other specimens inhabited the oesophagus in four frogs sharing this site with *B. slomei*. *Camallanus xenopodis* is found only in the intestine of *X. laevis* and no other nematode species are known from this part of the digestive tract.

The reported morphometric characters of *B. slomei* vary widely and correspond to the previously known data (Southwell and Kirshner 1937, Jackson and Tinsley 1995b). Our data slightly expand the existing ranges of body length and width, length of male spicules and distance to vulva from anterior part of body in females. Overall, no differences in morphometric characters of *B. slomei* were observed between localities.

Metrical characters of *C. kaapstaadi* and *C. xenopodis* also vary greatly in the studied samples, though most of them fall within the ranges of previously known data (Southwell and Kirshner 1937, Thurston 1970, Jackson and Tinsley 1995a). In the first description of *C. kaapstaadi*, the authors mentioned that the male left spicule is about 200 µm long and less sclerotised than the right one (Southwell and Kirshner 1937). In the later redescription, the authors concurred that the left spicule is poorly visible, but did provide a mean measurement of 155 µm (Jackson and Tinsley 1995a). In our specimens, all males of *C. kaapstaadi* possessed a conspicuous left spicule with a mean length of about 212 µm. This measurement is longer than that reported for *C. kaapstaadi* from *X. laevis* by Jackson and Tinsley (1995a), probably due to the fact that the specimens in our study were generally bigger (2.25 mm in Jackson and Tinsley (1995a) vs 3.04 mm in the present study). This discrepancy is also found in the mean measurement of the right spicule (273 µm vs 423 µm). At the same time, the left spicule of *C. xenopodis* is truly inconspicuous under light microscopy, even when viewed under high magnification with differential interference contrast (DIC). Nevertheless, the existence of the left spicule is confirmed based on dissection of the caudal part of male. In our specimens, more females than males of all the species were found, although only in *C. xenopodis* the females are four times more frequent. Therefore, it is clear why the species was previously described only by females (Jackson and Tinsley 1995a). Males in our samples of *C. xenopodis* possess several characters, such as structure of buccal capsule, number of ridges on its valves, size and shape of tridents and male right spicule, that are similar to *C. mazabukae* Kung, 1948. Despite that, two characters, namely number of mucrons (five or at least four in *C. mazabukae* versus only three in *C. xenopodis*) and the shape of the body (*C. mazabukae* coiled in the ventral direction whilst all found specimens of *C. xenopodis* coiled dorsally) led us to assign the collected specimens to *C. xenopodis*.

However, the image of the female tail of *C. mazabukae* in the original description (Kung 1948) shows that the specimen might really be coiled dorsally. Moreover, the species was described based on only two specimens from the poorly identified host, marked as “bullfrog”. Since no *Camallanus* have been found in the giant bullfrog (*Pyxicephalus adspersus* Tschudi) or African bullfrog (*Pyxicephalus edulis* Peters) (Halajian et al. 2013, unpubl. data) before this record or ever since, we suppose that it might represent an opportunistic infection or host misidentification. Given these points, we prefer to identify our specimens as *C. xenopodis* while the taxonomic status of *C. mazabukae* should be illuminated by further studies of *Camallanus* from different amphibians in Africa.

The lack of available DNA alignments in GenBank did not allow us to provide robust phylogenetic analysis of the found species. Both phylogenetic trees (based on partial 28S and cox1 alignments) show that species of *Camallanus* from South African amphibians form a well-supported clade separate from clades of species from Asian fish or Australian freshwater turtles. Unfortunately, we are not able to consider that group as monophyletic, since no data are available of *Camallanus* from fish (*C. polypteri* Ka-bre et Petter, 1997) or turtles (*C. cheloni*us Baker, 1983) in Africa.

Our study revealed only one species of *Batrachocamallanus*, which limits us in our ability to draw conclusions about the status of the genus. Both the opinions of Jackson and Tinsley (1995b) and Moravec et al. (2006) are based on the morphological characters of nematodes. Recent molecular studies of different groups of nematodes established that morphological characters (especially apomorphies) may appear independently in different lineages.
and are often not suitable for phylogenetic studies (Carreno and Nadler 2003, Tkach et al. 2014). Therefore, in our opinion, the real phylogeny and evolutionary relationships between Camallanidae and their hosts will be illuminated in further molecular studies of more species from different hosts around the globe.
