Abstract. We investigate the associated production of charged Higgs bosons ($H^\pm$) and $W$ bosons at the CERN Large Hadron Collider, using the leptonic decay $H^+ \rightarrow \tau^+ \nu_\tau$ and hadronic $W$ decay, within different scenarios of the Minimal Supersymmetric Standard Model (MSSM) with both real and complex parameters. Performing a parton level study we show how the irreducible Standard Model background from $W + 2$ jets can be controlled by applying appropriate cuts. In the standard $m_h^{\max}$ scenario we find a viable signal for large $\tan \beta$ and intermediate $H^\pm$ masses ($\sim m_t$). In MSSM scenarios with large mass-splittings among the heavy Higgs bosons the cross-section can be resonantly enhanced by factors up to one hundred, with a strong dependence on the CP-violating phases.

PACS. 14.80.Cp Non-standard-model Higgs bosons – 12.60.Jv Supersymmetric models

1 Introduction

One of the main tasks at the upcoming experiments at the CERN Large Hadron Collider (LHC) is the determination of the mechanisms of electroweak symmetry breaking and of the generation of elementary particle masses. In the Minimal Supersymmetric Standard Model (MSSM), which is a two Higgs Doublet Model (2HDM) of type II, the Higgs sector consists of three neutral and one charged Higgs bosons after electroweak symmetry breaking. The charged Higgs boson ($H^\pm$) is of special interest since its discovery would constitute an indisputable proof of physics beyond the Standard Model (SM).

The main production mode of charged Higgs bosons at hadron colliders is in association with top quarks through the $gb \rightarrow H^- t$ and $gg \rightarrow H^- t\bar{b}$ processes [6, 8, 9, 10, 11, 12, 13, 14] with the former one being dominant for heavy charged Higgs bosons $m_{H^\pm} \gtrsim m_t$ and the latter one for light ones $m_{H^\pm} \lesssim m_t - m_b$. A complementary production mode of charged Higgs bosons is in association with $W$-bosons [8, 9, 10, 11, 12, 13, 14]. Although the production cross-section [8, 9] is large, an earlier study [10] using the hadronic charged Higgs decay, $H^\pm \rightarrow t\bar{b}$, came to the conclusion that the signal is overwhelmed by the $t\bar{t}$ background.

Here, we report results of our study [13] of the prospects of using instead the $H^+ \rightarrow \tau^+ \nu_\tau$ decay together with $W \rightarrow 2$ jets in the MSSM with both real and complex parameters. In the following we first outline the simulation of $H^\pm W^\mp$ production and decay at the LHC and then give our results for the standard maximal mixing ($m_h^{\max}$) scenario as well as for scenarios with resonantly enhanced cross section. For more details we refer to [13].

2 Simulation and signal selection

The dominant production mechanisms for $H^\pm W^\mp$ at hadron colliders are $b\bar{b}$ annihilation at tree-level and gluon fusion at one-loop-level. Here, we focus on the parameter region with intermediate $H^\pm$ masses ($\sim m_t$) and large $\tan \beta$, where the decay $H^\pm \rightarrow \tau^\pm \nu_\tau$ has a large branching ratio and where the $b\bar{b}$ annihilation dominates. We have implemented [15] the two processes $b\bar{b} \rightarrow H^\pm W^\mp$ and $b\bar{b} \rightarrow H^\mp W^\pm$ as separate external processes to PYTHIA [16]. For the calculation of the MSSM scenario and the corresponding Higgs masses and the branching ratios of $H^\pm$ we use FEYNHIGGS 2.2.10 [17]. We only consider hadronic $\tau$ decays, $\tau \rightarrow \nu_\tau + \tau_{\text{jet}}$, which are performed using the program TAUOLA [18] in order to properly take into account the spin effects, resulting in the signature $2j + \tau_{\text{jet}} + p_{\perp}$.

The dominant irreducible SM background arises from $W + 2$ jets production which we have simulated with help of the package ALPGEN [19] again complemented with TAUOLA to perform the $\tau$ decay.

Since this study is performed at parton level, without any parton showering or hadronisation, the momenta of the jets are smeared as a first approximation to take these, as well as detector effects, into account. After smearing the following basic cuts are applied: $|\eta_{\text{jet}}| < 2.5$, $|\eta_j| < 2.5$, $\Delta R_{jj} > 0.4$, $\Delta R_{\tau_{\text{jet}}j} > 0.5$, and $p_{\perp \text{jet}} > 20$ GeV. We then apply the further cuts given in table 1 in order to suppress the background,
Table 1. The effect of the different cuts on the integrated cross-section for background ($\sigma_b$) and signal ($\sigma_s$) in the $m_h^{\text{max}}$ scenario with $m_H^\pm = 175$ and 400 GeV for $\tan \beta = 50$ as well as the number of signal events $S$ and the significance $S/\sqrt{B}$ assuming an integrated luminosity of 300 fb$^{-1}$ and a $\tau$ detection efficiency of 30%.

| Cut [all in GeV] | $\sigma_b$ (fb) | $\sigma_s$ (fb) | $S$ | $S/\sqrt{B}$ | $\sigma_s$ (fb) | $S$ | $S/\sqrt{B}$ |
|------------------|-----------------|-----------------|-----|-------------|-----------------|-----|-------------|
| Basic cuts       | 560000          | 55              | 4900 | 0.7         | 3.3             | 300 | 0.04        |
| $p_{\perp \tau_\ell} > 50$, $p_{\perp} > 50$ | 22000          | 25              | 2200 | 1.6         | 2.7             | 240 | 0.2         |
| $70 < m_{jj} < 90$ | 1700           | 21              | 1900 | 5           | 2.2             | 200 | 0.5         |
| $m_\perp > 100$   | 77              | 15              | 1400 | 16          | 2.1             | 190 | 2.3         |
| $p_{\perp hj} > 50$, $p_{\perp sj} > 25$ | 28             | 9.3             | 840  | 17          | 1.5             | 135 | 2.6         |

Fig. 1. Upper row: $H^\pm$ mass and $\tan \beta$ dependence of the integrated cross-section in the $m_h^{\text{max}}$ scenario. Solid curves are with all cuts of table 1 and dashed curves are with the harder cuts $p_{\perp \tau_\ell}, p_\perp > 100$ GeV. The horizontal lines correspond to $S/\sqrt{B} = 5$. Lower row: $m_\perp$ distribution for the signal (dashed) in the $m_h^{\text{max}}$ scenario with $\tan \beta = 50$ and $m_H^\pm = 175$ GeV (left) as well as $m_H^\pm = 400$ GeV (right) together with the background (dotted) with all cuts of table 1 (for $m_H^\pm = 400$ GeV the cuts $p_{\perp \tau_\ell}, p_\perp > 100$ GeV are used).

where $m_\perp = \sqrt{2m_{\perp \tau_\ell} m_\perp [1 - \cos(\Delta \phi)]}$ (with $\Delta \phi$ being the azimuthal angle between $p_{\perp \tau_\ell}$ and $p_\perp$) is the transverse mass and $p_{\perp hj}$ ($p_{\perp sj}$) is the harder (softer) of the two jets. The cuts $p_{\perp}, p_{\perp \tau_\ell} > 50$ GeV are primarily included to take the reducible QCD background into account, which has not been simulated explicitly. In order to estimate the sensitivity of the final results due to this choice we have also used an alternative set of harder cuts, $p_{\perp}, p_{\perp \tau_\ell} > 100$ GeV.

3 Standard MSSM scenarios

The signal cross-sections in the standard $m_h^{\text{max}}$ scenario as well as the resulting number of events and the significance $S/\sqrt{B}$ are given in table 1 for the MSSM parameters $\mu = 200$ GeV, $M_{\text{SUSY}} = 1$ TeV, $A_t = A_b = A_\tau = 2$ TeV, $M_2 = 200$ GeV, and $m_\tilde{g} = 800$ GeV. The upper row in fig. 1 shows the $m_H^\pm$ and $\tan \beta$ dependence of the cross-section after all cuts of table 1 (solid curves) and after the harder cuts $p_{\perp \tau_\ell}, p_\perp > 100$ GeV (dashed curves). The horizontal lines indicate the cross-section needed for $S/\sqrt{B} = 5$, corresponding to $\tan \beta \gtrsim 30$ if $m_{H^\pm} = 175$ GeV and 150 GeV $\lesssim m_{H^\pm} \lesssim 300$ GeV if $\tan \beta = 50$ with the softer cuts $p_{\perp \tau_\ell}, p_\perp > 50$ GeV, whereas with the harder cuts $\tan \beta$ has to be larger than at least 50.

The lower row in fig. 1 shows the resulting $m_\perp$ distribution for $m_{H^\pm} = 175$ GeV as well as $m_{H^\pm} = 400$ GeV in the case $\tan \beta = 50$ compared to the background after all cuts in table 1 have been applied.
The leading contributions to CP violation in the neutral Higgs sector and thus possibly affect our signal process because of the possibly complex Higgs/higgsino mass parameter and (to a lesser extend) of the scalar bottom sector. The leading contributions to CP violation in the neutral Higgs sector arise from loops of the scalar top and (to a lesser extend) of the scalar bottom sector where the possibly complex Higgs/higgsino mass parameter \( \mu \) and the trilinear scalar couplings \( A_t \) and \( A_b \) are dominant. Hence, assuming \( \phi_{A_t} = \phi_{A_b} \) we concentrate in the following on the phases \( \phi_{\mu} \) and \( \phi_{A_t} \) of \( \mu \) and \( A_t \), respectively, which have the largest effect on the neutral Higgs sector and thus possibly affect our signal.

5 MSSM with complex parameters

In the general MSSM many parameters can be complex. Then explicit CP violation occurs also in the Higgs sector through loops of supersymmetric particles [20, 23], which affects our signal process because of the neutral Higgs bosons exchanged in the s-channel. The leading contributions to CP violation in the neutral Higgs sector arise from loops of the scalar top and (to a lesser extend) of the scalar bottom sector where the possibly complex Higgs/higgsino mass parameter \( \mu \) and the trilinear scalar couplings \( A_t \) and \( A_b \) are dominant. Hence, assuming \( \phi_{A_t} = \phi_{A_b} \) we concentrate in the following on the phases \( \phi_{\mu} \) and \( \phi_{A_t} \) of \( \mu \) and \( A_t \), respectively, which have the largest effect on the neutral Higgs sector and thus possibly affect our signal.

Despite the fact that the SUSY phases may be severely constrained by bounds on the Electric Dipole Moments (EDMs), these constraints are rather model dependent and may be evaded in scenarios with heavy first and second generation sfermions, due to cancellations among various contributions to the EDMs or due to additional contributions from lepton flavour violating terms in the Lagrangian, for a review see e.g. [24].

Thus, we have varied \( \phi_{\mu} \) and \( \phi_{A_t} \) independently in the range \( -\pi < \phi < \pi \) in order to investigate the phase dependence of our signal.

In standard MSSM scenarios, such as the \( m_\mu^{\text{max}} \) scenario, we find only small (\( \sim 5\% \)) \( \phi_{\mu} \) and \( \phi_{A_t} \) dependencies of our signal cross-section as shown in the left plot in fig. 3. The right plot in fig. 3 shows the dependence of the cross-section on \( \phi_{\mu} \) in the resonant scenario of table 2 where the Higgs masses, couplings and widths have been calculated with FeynHiggs at one-loop accuracy.
The very large phase dependence in this scenario is due to the fact that the production goes from non-resonant to resonant when the phase is varied. More specifically, we get non-resonant to resonant when the phase is varied.

In principle, the process under study also offers the possibility to explore effects of CP violation via a CP-odd rate asymmetry $A_{\text{CP}}$ between $\sigma(pp \to H^+W^-)$ and $\sigma(pp \to H^-W^+)$. However, in all considered MSSM scenarios we find that $A_{\text{CP}}$ is smaller than about 1%.
