Perverse coherent sheaves on blowup, III: Blow-up formula from wall-crossing

Hiraku Nakajima and Kōta Yoshioka

To the memory of the late Professor Masaki Maruyama

Abstract In earlier papers of this series we constructed a sequence of intermediate moduli spaces \( \{ \tilde{M}^m(c) \}_{m=0,1,2,...} \) connecting a moduli space \( M(c) \) of stable torsion-free sheaves on a nonsingular complex projective surface \( X \) and \( \tilde{M}(c) \) on its one-point blow-up \( \tilde{X} \). They are moduli spaces of perverse coherent sheaves on \( \tilde{X} \). In this paper we study how Donaldson-type invariants (integrals of cohomology classes given by universal sheaves) change from \( \tilde{M}^m(c) \) to \( \tilde{M}^{m+1}(c) \) and then from \( M(c) \) to \( \tilde{M}(c) \). As an application we prove that Nekrasov-type partition functions satisfy certain equations that determine invariants recursively in second Chern classes. They are generalizations of the blow-up equation for the original Nekrasov deformed partition function for the pure \( \mathbb{N} = 2 \) supersymmetric gauge theory, found and used to derive the Seiberg-Witten curves.

0. Introduction

Let \( X \) be a nonsingular complex projective surface, and let \( p: \tilde{X} \to X \) be the blowup at a point zero. Let \( C = p^{-1}(0) \) be the exceptional divisor. Let \( c = (r, c_1, c_2) \in H^{ev}(\tilde{X}) \) be cohomological data. Let \( \tilde{M}(c) \) be the moduli space of stable torsion-free sheaves \( E \) on \( \tilde{X} \) with \( ch(E) = c \) and \( M(p_*(c)) \) the corresponding moduli space on \( X \). In [21] and [22] we constructed a sequence of intermediate moduli

moduli spaces $\hat{M}^m(c)$ connected by birational morphisms as
\[ \cdots \xrightarrow{\xi_m} \hat{M}^m(c) \xrightarrow{\xi_{m+1}} \hat{M}^{m+1}(c) \cdots \]
such that
\[ \begin{align*}
(1) & \quad \hat{M}^m(c) \cong \hat{M}(c) \text{ if } m \text{ is sufficiently large and } \\
(2) & \quad \hat{M}^0(c) \cong M(p_*(c)) \text{ if } (c_1, [C]) = 0 \text{ under the natural homomorphism given } \end{align*} 
\]
by $E \mapsto p_*(E)$ (see Proposition 1.2 for the statement when $0 < (c_1, [C]) < r$).

The diagram (*) is an example of those often appearing in variations of geometric invariant theory (GIT) quotients (see [27]) and is similar to ones for moduli spaces of sheaves (by Thaddeus, Ellingsrud and Göttsche, Friedman and Qin, and others) when we move polarizations (see [21], [22] for more references on earlier works).

In this paper, we study how Donaldson-type invariants (certain integrals of cohomology classes given by universal sheaves) change from $\hat{M}^m(c)$ to $\hat{M}^{m+1}(c)$. For a technical reason we restrict ourselves to the case when $X = \mathbb{P}^2$, and $\hat{M}^m(c)$ is replaced by the moduli space of framed sheaves for which the quiver description was given in [22]. We conjecture that the results are universal, that is, independent of the choice of a surface. Moreover, we have a natural $(r + 1)$-dimensional torus $\tilde{T} = (\mathbb{C}^*)^2 \times T^{r-1}$ action on $\hat{M}^m(c)$ from the $(\mathbb{C}^*)^2$-action on $\mathbb{P}^2$ and the change of framing. Thus we can consider equivariant Donaldson-type invariants to which we can apply the Atiyah-Bott-Berline-Vergne fixed-point formula to perform a further computation. In this sense, we think our situation is most basic.

Our first main result says that the difference of invariants is given by a variant of Mochizuki’s weak wall-crossing formula (see [14]); that is, it is expressed as a sum of an integral over $\hat{M}^m(c')$ with smaller $c'$ (see Theorem 1.5). Our argument closely follows Mochizuki’s, once (*) is understood as a variation of GIT quotients.

Summing up the weak wall-crossing formula from zero to $m$, we get the formula for the difference of $\hat{M}(c)$ and $M(p_*(c))$ by integrals over various $\hat{M}^m(c')$ as a result. We normalize the first Chern class of $c'$ in the interval $[0, r-1]$, twisting by a line bundle to apply $M(p_*(c')) \cong \hat{M}^0(c')$ for $(c_1(c'), [C]) = 0$ and its modification Proposition 1.2. Then those integrals themselves can be expressed by integrals over $M(p_*(c'))$ and ones over even smaller $\hat{M}^{m''}(c'')$. We apply the same argument for $\hat{M}^{m''}(c'')$. We thus do this argument recursively to give an algorithm to express $\hat{M}(c)$ by a linear combination of integrals over $M(c_b)$ for various $c_b$. Since this algorithm is complicated (see Figure 1 for the flowchart), we do not try to write down an explicit formula in general. We instead focus on vanishing theorems for special cases when integrands are not twisted too much along $C$. This is our second main result (see Section 2).

Our motivation for study in this series is an application to the Nekrasov partition function (see [24]). Let us explain it briefly. The Nekrasov partition
function is the generating function of an equivariant integral over $M(c)$. One of the main conjectures on it states that the leading part $F_0$ of its logarithm is given by the Seiberg-Witten prepotential, a certain period integral on the Seiberg-Witten curves. The three consecutive coefficients (denoted by $H$, $A$, $B$) are also important for the application to the wall-crossing formula for usual or $K$-theoretic Donaldson invariants for projective surfaces with $p_g = 0$ (see [7], [8]).

When the integrand is

1. $1$,
2. slant products of Chern classes of universal sheaves with the fundamental classes of $C^2$, or
3. the Todd class of $M(c)$,

the authors proved that the partition function satisfies functional equations called the blow-up equations, which determine coefficients recursively in second Chern numbers of $c$ (see [18]–[20]). The functional equations induce a nonlinear partial differential equation for $F_0$, which has been known as the contact term equation in physics literature (see [12], [6]). In particular, the Seiberg-Witten prepotential satisfies the same equation and hence is equal to $F_0$. This was our proof of the above-mentioned conjecture. There are other completely independent proofs in [25] and [2]. But so far, $H$, $A$, $B$ can be determined only from the blow-up equation.

Nekrasov’s partition functions have more variants by replacing the integrand. Let us give three examples.

(a) We integrate Euler classes of vector bundles given by the pushforward of universal sheaves. They are called the theories with fundamental matters in physics literature.

(b) When we integrate the Todd classes, we can cap with powers of the first Chern classes of the same bundles. They are called 5-dimensional Chern-Simons terms.

(c) We can also incorporate universal sheaves to which Adams operators are applied. They are called (higher) Casimir operators. They give coefficients appearing in the defining equation of the Seiberg-Witten curve.

The blow-up equation was derived by analyzing relations between integrals over $M(c)$ and $\hat{M}(c)$. Our vanishing results in Section 2 enable us to generalize our proof for those variants. In this paper, we explain it for theories with 5-dimensional Chern-Simons terms and Casimir operators. The case for the theories with matters will be given elsewhere (see [23]).

The paper is organized as follows. In Section 1 we state our results after preparing the necessary notation. In Section 2 we prove several versions of vanishing theorems as applications of the results in Section 1. In Section 3 we study

*The proof in [25] can be generalized to those variants (see [26] for the theory with 5-dimensional Chern-Simons terms and [13] for higher Casimir operators, but not with Todd genus).
the Nekrasov partition function for theories with 5-dimensional Chern-Simons terms. The blow-up equation is derived. This section is expository since the derivation of Nekrasov’s conjecture was already given in [8] assuming the vanishing theorems.

The actual proof starts from Section 4. We review the quiver description of the framed moduli spaces obtained in [22] and the analysis of the wall crossing in [21], and we add a few things. The quiver description is necessary to define master spaces. In Section 5 we define enhanced master spaces. We follow Mochizuki’s method (see [14]), but give the construction in detail for the sake of the reader. In Section 6 we prove Theorem 1.5, the variant of Mochizuki’s weak wall-crossing formula. Again the proof is the same as Mochizuki’s.

1. Main result

Notation

Let \([z_0 : z_1 : z_2]\) be the homogeneous coordinates on \(\mathbb{P}^2\), and let \(\ell_\infty = \{z_0 = 0\}\) be the line at infinity. Let \(p: \mathbb{P}^2 \to \mathbb{P}^2\) be the blow-up of \(\mathbb{P}^2\) at \([1:0:0]\). Then \(\mathbb{P}^2\) is the closed subvariety of \(\mathbb{P}^2 \times \mathbb{P}^1\) defined by

\[\{([z_0 : z_1 : z_2], [z : w]) \in \mathbb{P}^2 \times \mathbb{P}^1 | z_1 w = z_2 z\}\],

where the map \(p\) is the projection to the first factor. We denote \(p^{-1}(\ell_\infty)\) also by \(\ell_\infty\) for brevity. Let \(C\) denote the exceptional divisor given by \(z_1 = z_2 = 0\).

Let \(\mathcal{O}\) denote the structure sheaf of \(\mathbb{P}^2\), let \(\mathcal{O}(C)\) be the line bundle associated with the divisor \(C\), and let \(\mathcal{O}(mC)\) be its \(m\)th tensor product \(\mathcal{O}(C) \otimes^m\) when \(m > 0\), \((\mathcal{O}(C) \otimes^{-m})^\vee\) if \(m < 0\), and \(\mathcal{O}\) if \(m = 0\). And we use the similar notion \(\mathcal{O}(mC + n\ell_\infty)\) for tensor products of \(\mathcal{O}(mC)\) and tensor powers of the line bundle corresponding to \(\ell_\infty\) or its dual.

The structure sheaf of the exceptional divisor \(C\) is denoted by \(\mathcal{O}_C\). If we twist it by the line bundle \(\mathcal{O}_{\mathbb{P}^1}(n)\) over \(C \cong \mathbb{P}^1\), we denote the resulted sheaf by \(\mathcal{O}_C(n)\). Since \(C\) has the self-intersection number \(-1\), we have \(\mathcal{O}_C \otimes \mathcal{O}(C) = \mathcal{O}_C(-1)\).

For \(c \in H^*(\mathbb{P}^2)\), its degree \((0, 2, 4)\)-parts are denoted by \(r, c_1, \text{ch}_2\), respectively. If we want to specify \(c\), we denote \(r(c), c_1(c), \text{ch}_2(c)\).

For brevity, we twist the pushforward homomorphism \(p_*\) by Todd genera of \(\mathbb{P}^2\) and \(\mathbb{P}^2\) as in [21, Section 3.1] so that it is compatible with the Riemann-Roch formula.

We also use the following notation frequently:

- \(\vee\) is the involution on the \(K\)-group given by taking the dual of a vector bundle;
- \(\Delta(E) := c_2(E) = (r-1)/(2r)c_1(E)^2, \Delta(c) := -\text{ch}_2(c) + (1/(2r(c)))c_1(c)^2;\)
- \(C_m\) denotes \(\mathcal{O}_C(-m - 1)\);
- \(e_m := \text{ch} \mathcal{O}_C(-m - 1)\);
- \(\text{pt}\) is a single point in \(X\), \(\hat{X}\) or sometimes an abstract point; its Poincaré dual in \(H^4(X)\) or \(H^4(\hat{X})\) is also denoted by the same notation;
- for an integer \(N\), let \(\underline{N} = \{1, 2, \ldots, N\}\).
For a sheaf \( E \) on \( \widehat{\mathbb{P}}^2 \), we denote \( H^1(E(-\ell_\infty)) \), \( H^1(E(C - \ell_\infty)) \) by \( V_0(E) \), \( V_1(E) \), respectively (and simply by \( V_0 \), \( V_1 \) if there is no fear of confusion). In this paper we mainly treat sheaves \( E \) with \( H^i(E(-\ell_\infty)) = 0 = H^i(E(C - \ell_\infty)) \) for \( i \neq 1 \). This is clear after we recall the quiver description of framed moduli spaces in Section 4: \( V_\alpha \) appears as a vector space on the vertex \( \alpha \), and any sheaf in this paper corresponds to a representation of the quiver. Under this assumption we have
\[
\dim V_0 = \dim H^1(E(-\ell_\infty)) = -\left( \text{ch}_2(E), \left[ \widehat{\mathbb{P}}^2 \right] \right) + \frac{1}{2} \left( c_1(E), [C] \right),
\]
\[
\dim V_1 = \dim H^1(E(C - \ell_\infty)) = -\left( \text{ch}_2(E), \left[ \widehat{\mathbb{P}}^2 \right] \right) - \frac{1}{2} \left( c_1(E), [C] \right)
\]
by Riemann-Roch.

Let \( \widehat{M} \) be a moduli scheme (or stack), and let \( q_1, q_2 \) be projections to the first and second factors of \( \widehat{\mathbb{P}}^2 \times \widehat{M} \). For a sheaf \( E \) (e.g., the universal sheaf) on \( \widehat{\mathbb{P}}^2 \times \widehat{M} \), let
\[
\begin{align*}
\cdot V_0(E) &:= R^1 q_{2*}(E \otimes q_1^* \mathcal{O}(-\ell_\infty)), \\
\cdot V_1(E) &:= R^1 q_{2*}(E \otimes q_1^* \mathcal{O}(C - \ell_\infty)).
\end{align*}
\]
Let \( \text{Ext}^\bullet \) denote the derived functor of the composite functor \( q_{2*} \circ \text{Hom} \). We often consider \( \text{Ext}^\bullet(q_2^*(E, C_m)) \), where \( C_m \) is considered as a sheaf on \( \widehat{\mathbb{P}}^2 \times \widehat{M} \) via the pullback by \( q_1 \).

### 1.1. Framed moduli spaces

A framed sheaf \((E, \Phi)\) on \( \mathbb{P}^2 \) is a pair of
\[
\begin{align*}
\cdot & \quad \text{a coherent sheaf } E, \text{ which is locally free in a neighborhood of } \ell_\infty, \text{ and} \\
\cdot & \quad \text{an isomorphism } \Phi: E|_{\ell_\infty} \to \mathcal{O}^r_{\ell_\infty}, \text{ where } r \text{ is the rank of } E.
\end{align*}
\]
An isomorphism of framed sheaves \((E, \Phi), (E', \Phi')\) is an isomorphism \( \xi: E \to E' \) such that \( \Phi' \circ \xi|_{\ell_\infty} = \Phi \). When \( r = 0 \), we understand that a framed sheaf is an ordinary sheaf of rank zero whose support does not intersect with \( \ell_\infty \). We have the corresponding definition of a framed sheaf on the blowup \( \widehat{\mathbb{P}}^2 \).

**DEFINITION 1.1**

Let \( m \in \mathbb{Z}_{\geq 0} \). A framed sheaf \((E, \Phi)\) on \( \widehat{\mathbb{P}}^2 \) is called \( m \)-stable if
\[
\begin{align*}
(1) \quad & \quad \text{Hom}(E, \mathcal{O}_C(-m - 1)) = 0, \\
(2) \quad & \quad \text{Hom}(\mathcal{O}_C(-m), E) = 0, \text{ and} \\
(3) \quad & \quad E \text{ is torsion free outside } C.
\end{align*}
\]

Though it is not obvious from the definition, an \( m \)-stable sheaf must have \( r > 0 \) (see [22, Section 2.2]).

We have a smooth fine moduli scheme \( \widehat{M}^m(c) \) of \( m \)-stable framed sheaves \((E, \Phi)\) with \( \text{ch}(E) = c \in H^*(\widehat{\mathbb{P}}^2) \) such that \( (c, [\ell_\infty]) = 0 \). It is of dimension
Suppose (see Theorem 4.2). Let $E$ be the universal sheaf on $\mathbb{P}^2 \times \hat{M}^m(c)$, which is unique thanks to the framing, unlike the case of ordinary moduli spaces.

As special cases with $m = 0$ and $m$ sufficiently large, we have fine moduli schemes $M(c)$ and $\hat{M}(c)$ of framed torsion-free sheaves $(E, \Phi)$ on $\mathbb{P}^2$ and $\hat{\mathbb{P}}^2$, respectively. For $M(c)$, we take $c \in H^*(\hat{\mathbb{P}}^2)$ with $(c_1, [C]) = 0$ (see [22, Section 7] or [21, Sections 3.1, 3.9]). They are connected by a sequence of birational morphisms as explained in the introduction (see Section 4.4).

In fact, $M(c)$ was studied earlier in [17, Chapters 2, 3] (denoted there by $\mathcal{M}(r, n)$). We need to recall one important property. We have a projective morphism $\pi: M(c) \to M_0(c)$, where $M_0(c)$ is the Uhlenbeck (partial) compactification of the moduli space $M^0_{\text{reg}}(c)$ of framed locally free sheaves $(E, \Phi)$. In [17] $M_0(c)$ was constructed via the quiver description and bijective to $\bigsqcup M^0_{\text{reg}}(c') \otimes S^{\Delta(c) - \Delta(c')}(\mathbb{C}^2)$ set-theoretically. Here $S^n(\mathbb{C}^2)$ denotes the $n$th symmetric product of $\mathbb{C}^2$.

For any $m$, we still have a projective morphism $\hat{\pi}: \hat{M}^m(c) \to M_0(p_s(c))$. This follows from the quiver description (see Theorem 4.2) or [21, Section 3.2]. It is compatible with the diagram (1) and induced from a projective morphism $\hat{M}^{m,m+1}(c) \to M_0(p_s(c))$.

1.2. Grassmann bundle structure

As we mentioned above, we have $M^0(c) \cong M(p_s(c))$ when $(c_1, [C]) = 0$. For $0 < (c_1, [C]) < r$, we have a similar relation as follows. We need to consider $\hat{M}^1(c)$ with $0 > (c_1, [C]) > -r$ instead after twisting by the line bundle $\mathcal{O}(C)$.

PROPOSITION 1.2 [21, SECTION 3.10]

Suppose $0 < n := -(c_1, [C]) < r$. There is a variety $\hat{N}(c,n)$ relating $\hat{M}^1(c)$ and $\hat{M}^1(c - n\varepsilon_0)$ through a diagram

\[
\begin{array}{ccc}
\hat{N}(c,n) & \xrightarrow{f_1} & \hat{M}^1(c) \\
\hat{M}^1(c - n\varepsilon_0) & \xleftarrow{f_2} & \\
\end{array}
\]

satisfying the following:

1. $f_1$ is surjective and birational;
2. $f_2$ is the Grassmann bundle $\text{Gr}(n, \text{Ext}^1_{q_2}(\mathcal{O}_C(-1), \mathcal{E}'))$ of $n$-planes in the vector bundle $\text{Ext}^1_{q_2}(\mathcal{O}_C(-1), \mathcal{E}')$ of rank $r$ over $\hat{M}^1(c - n\varepsilon_0)$;
3. we have a short exact sequence

\[
0 \to (\text{id}_{\mathcal{E}} \times f_2)^* \mathcal{E}' \to (\text{id}_{\mathcal{E}} \times f_1)^* \mathcal{E} \to \mathcal{O}_C(-1) \boxtimes \mathcal{S} \to 0.
\]

Here $\mathcal{E}$, $\mathcal{E}'$ are the universal sheaves for $\hat{M}^1(c)$ and $\hat{M}^1(c - n\varepsilon_0)$, respectively, and $\mathcal{S}$ is the universal rank $n$ subbundle of $\text{Ext}^1_{q_2}(\mathcal{O}_C(-1), \mathcal{E}')$ over $\text{Gr}(n, \text{Ext}^1_{q_2} \times (\mathcal{O}_C(-1), \mathcal{E}'))$. 
Note that $\operatorname{Ext}^i_{\mathcal{Q}}(\mathcal{O}_C(-1), \mathcal{E}') = 0$ for $i = 0, 2$ by the remark after Lemma 4.11. Hence $\operatorname{Ext}^1_{\mathcal{Q}}(\mathcal{O}_C(-1), \mathcal{E}')$ is a vector bundle, and its rank is $r$ by Riemann-Roch.

We have $(c_1(c - ne_0), [C]) = (c_1, [C]) + n = 0$. Therefore $\hat{M}^1(c - ne_0)$ becomes $M(p_*(c))$ after crossing the wall between zero-stability and 1-stability.

1.3. Torus action and equivariant homology groups

Let $T$ be the maximal torus of $\text{SL}_r(\mathbb{C})$ consisting of diagonal matrices, and let $\tilde{T} = \mathbb{C}^* \times \mathbb{C}^* \times T$. We have a $\tilde{T}$-action on $\tilde{M}^m(c)$ induced from the $(\mathbb{C}^* \times \mathbb{C}^*)$-action on $\mathbb{C}^2$ given by

$$(\begin{bmatrix} z_0 : z_1 : z_2 \end{bmatrix}, [z : w]) \mapsto (\begin{bmatrix} t_1 z_1 : t_2 z_2 \end{bmatrix}, [t_1 z : t_2 w])$$

and the change of the framing $\Phi$ (see [21, Section 5]). It was defined exactly as in the case of framed moduli spaces of torsion-free sheaves, given in [19, Section 3]. The action is compatible with one on $M_0(c)$; that is, $\tilde{\pi}$ is $\tilde{T}$-equivariant. All the constructions that we have explained so far are canonically $\tilde{T}$-equivariant. For example, we have the canonical $\tilde{T}$-action on the universal sheaf $\mathcal{E}$.

Let $H^T_\tilde{T}(X)$ be the $\tilde{T}$-equivariant Borel-Moore homology group of a $\tilde{T}$-space $X$ with rational coefficients. Let $H^*_T(X)$ be the $\tilde{T}$-equivariant cohomology group with rational coefficients. They are defined for $X$ satisfying a reasonable condition, say an algebraic variety with an algebraic $\tilde{T}$-action (see, e.g., [18, Appendix C]). They are modules over the equivariant cohomology group $H^*_T(pt)$ of a point, isomorphic to the symmetric product of the dual of the Lie algebra, which we denote by $S(\tilde{T})$.

The projective morphism $\tilde{\pi}: \tilde{M}^m(c) \to M_0(p_*(c))$ induces a homomorphism

$$\tilde{\pi}_*: H^\tilde{T}_*(\tilde{M}^m(c)) \to H^\tilde{T}_*(M_0(p_*(c))).$$

We denote this homomorphism $\tilde{\pi}_*$ by $\int_{\tilde{M}^m(c)}$ since we also use similar pushforward homomorphisms from homology groups of various moduli schemes or stacks and want to emphasize the domain.

On the other hand, the target space $M_0(p_*(c))$ is not at all important. We can compose the pushforward homomorphism for the inclusion $M_0(p_*(c)) \subset M_0(c')$ for $\Delta(c') \geq \Delta(p_*(c))$. Then $\int_{\tilde{M}^m(c)}$ takes values in $H^\tilde{T}_*(M_0(c'))$. We can also make $\int_{\tilde{M}^m(c)}$ with values in $S(\tilde{T})$, the quotient field of $S(\tilde{T})$ as follows. Recall that $\tilde{T}$ has the unique fixed point zero in $M_0(p_*(c))$ (see [19, Proposition 2.9(3)]). We compose $\int_{\tilde{M}^m(c)}$ with the inverse $\iota_{0*}^{-1}$ of the pushforward homomorphism $\iota_{0*}$ for the inclusion $\{0\} \to M_0(p_*(c))$ by using the localization theorem for the equivariant homology group, which says that $\iota_{0*}$ becomes an isomorphism after taking tensor products with $S(\tilde{T})$ over $H^\tilde{T}_*(pt) = S(\tilde{T})$. This is compatible with the above inclusion (see [19, Section 4] for more details).

1.4. Weak wall-crossing formula

We state our first main result in this subsection.
Let $\Phi(\mathcal{E}) \in H^*(\hat{M}^m(c))$ be an equivariant cohomology class on $\hat{M}^m(c)$ defined from a sheaf $\mathcal{E}$ on $\hat{P}^2 \times \hat{M}^m(c)$ by taking a slant product by a cohomology class on $\hat{P}^2$ or taking a cohomology group, for example,

$$
\Phi(\mathcal{E}) := \exp \left[ \sum_{p=1}^{\infty} \left\{ t_p \text{ch}_p + \tau_p \text{ch}_p \right\} \right]
$$

or

$$
\Phi(\mathcal{E}) := \prod_{f=1}^{N_f} e\left(\mathcal{V}_a(\mathcal{E}) \otimes e^{m_f}\right) \quad a = 0 \text{ or } 1,
$$

where $t_p, \tau_p$ are variables and the exponential defines formal power series in $t_p, \tau_p$ in the first case; $m_1, \ldots, m_{N_f}$ are variables for the equivariant cohomology $H^*_{(\mathbb{C}^*)^{N_f}}(pt)$ of the $N_f$-dimensional torus of a point; and $e^{m_f}$ is the corresponding equivariant line bundle. For $\mathcal{E}$ we typically take the universal sheaf, or its variant. For the latter $\Phi(\mathcal{E}) = \prod_{f=1}^{N_f} e\left(\mathcal{V}_a(\mathcal{E}) \otimes e^{m_f}\right)$, we need to enlarge $\hat{T}$ to $\hat{T} \times (\mathbb{C}^*)^{N_f}$ but keep the notation $\hat{T}$ for brevity. And $e(\ )$ denotes the equivariant Euler class.

REMARK 1.4
The notation $N_f$ is taken from physics literature. It is the number of flavors. But we denote the rank by $r$, although it is denoted by $N_c$ (number of colors) in physics literature.

The above examples of $\Phi$ are multiplicative; that is, $\Phi(\mathcal{E} \oplus \mathcal{E}') = \Phi(\mathcal{E})\Phi(\mathcal{E}')$. This condition is useful when we study the vanishing theorem in Section 2, but we do not assume it in general.

For $j \in \mathbb{Z}_{>0}$ we consider the $j$-dimensional torus $(\mathbb{C}^*)^j$ acting trivially on moduli schemes. We denote the 1-dimensional weight $n$ representation of the $i$th factor by $e^{nh_i}$. The equivariant cohomology $H^*_{(\mathbb{C}^*)^j}(pt)$ of the point is identified with $\mathbb{C}[h_1, \ldots, h_j]$. In the following formula we invert variables $h_1, \ldots, h_j$ (see Section 6.1 for the precise definition). Also, we identify $\Phi(\mathcal{E})$ with the homology class $\Phi(\mathcal{E}) \cap [\hat{M}^{m+1}(c)]$ and apply the push-forward homomorphism $\int_{\hat{M}^{m+1}(c)}$.

THEOREM 1.5
We have

$$
\int_{\hat{M}^{m+1}(c)} \Phi(\mathcal{E}) - \int_{\hat{M}^{m}(c)} \Phi(\mathcal{E}) = \sum_{j=1}^{\infty} \int_{\hat{M}^{m}(c-j\epsilon_m)} \text{Res}_{h_1=0} \cdots \text{Res}_{h_j=0} \left[ \Phi(\mathcal{E}_0 \oplus \bigoplus_{i=1}^{j} C_{m \boxtimes e^{-h_i}}) \right] \Psi^j(\mathcal{E}_0).
$$
where $\mathcal{E}_x$ is the universal sheaf for $\bar{M}^m(c - je_m)$ and

$$\Psi^j(\mathcal{E}_x) := \frac{1}{j!} \prod_{i_1 \neq i_2 \leq j} (-h_{i_1} + h_{i_2}) \frac{\prod_{1 \leq i_1 \leq j} \mathcal{E}_y (C_m, C_m) \otimes e^{-h_{i_1}}}{\prod_{i_1 \leq i_2 \leq j} \mathcal{E}_y (C_m, C_m) \otimes e^{-h_{i_2}}},$$

with $\mathcal{E}_y := \mathcal{O}(C_m, C_m) \otimes e^{-h_{j_1}} \mathcal{E}_y$.

$$\mathcal{N}(\mathcal{E}_y, C_m) := -\sum_{n=0}^{\infty} (-1)^a \operatorname{Ext}^a_{\mathcal{O}(\mathcal{E}_y, \mathcal{E}_y)} (C_m, C_m),$$

$$\mathcal{N}(C_m, \mathcal{E}_y) := -\sum_{n=0}^{\infty} (-1)^a \operatorname{Ext}^a_{\mathcal{O}(\mathcal{E}_y, \mathcal{E}_y)} (C_m, C_m).$$

(Note that $\Psi^j(\mathcal{E}_x)$ depends on $j$ but not on $c - je_m$ if we consider $\mathcal{E}_x$ as a variable.)

The proof is given in Section 6.4.

### 1.5. Blow-up formula

Recall that $\bar{M}^m(c)$ is isomorphic to the framed moduli space $\hat{M}(c)$ of torsion-free sheaves on $\mathbb{P}^2$ if $m$ is sufficiently large. Using Proposition 1.2 and Theorem 1.5, and twisting by the line bundle $\mathcal{O}(C)$, we can express $\int_{\hat{M}(c)} \Phi(\mathcal{E})$ as a sum of various $\int_{\hat{M}(c')} \Phi(\mathcal{E})$'s for some $c'$, $\Phi'$. Unfortunately the procedure, which we explain below in detail, is recursive in nature and rather cumbersome (see Figure 1 for the flow chart). In particular, we do not solve the recursion and do not give the explicit formula.

#### 1.5.1

For a sequence $\vec{j} = (j_0, j_1, \ldots, j_{m-1}) \in \mathbb{Z}^m_{\geq 0}$, we define $\Psi^j_{m_n}$ recursively starting from $\Psi^j_{m_1} = 1$ by

$$\Psi^j_{m_n} (\bullet) := \Psi^j_{m_{n+1}} (\bullet \oplus C_n \otimes e^{-h_n}) \times \frac{1}{j_n!} \prod_{i_1 \neq i_2 \leq m_n} (-h_{i_1} + h_{i_2}) \frac{\prod_{1 \leq i_1 \leq m_n} (\mathcal{E}_y (C_m, C_m) \otimes e^{-h_{i_1}})}{\prod_{i_1 \leq i_2 \leq m_n} (\mathcal{E}_y (C_m, C_m) \otimes e^{-h_{i_2}})},$$

where $h_1, \ldots, h_{m_n}$ are variables. Then we set $\Psi^j = \Psi^j_0$. By Theorem 1.5, we get

$$\int_{\hat{M}^m(c)} \Phi(\mathcal{E})$$

(1.6)

$$= \sum_{\vec{j}} \int_{\hat{M}^0(c - \sum_{n=0}^{m_n} j_n e_n)} \underset{\vec{h}=0}{\text{Res}} \Phi\left(\mathcal{E}_y \oplus \bigoplus_{n=0}^{m_n-1} \bigoplus_{i=1}^{j_n} C_n \otimes e^{h_i}ight) \Psi^j(\mathcal{E}_y),$$

where $\underset{\vec{h}=0}{\text{Res}}$ is the iterated residues

$$\underset{\vec{h}=0}{\text{Res}} := \underset{h_0=0}{\text{Res}} \cdots \underset{h_{j_0}=0}{\text{Res}} \underset{h_{j_1}=0}{\text{Res}} \cdots \underset{h_{j_{m-1}}=0}{\text{Res}} \underset{h_{m-1}=0}{\text{Res}} \cdots \underset{h_{m-1}=0}{\text{Res}}.$$

Since $\hat{M}(c)$ is isomorphic to $\hat{M}^m(c)$ for a sufficiently large $m$, an integral over $\hat{M}(c)$ can be written in terms of integrals over $\hat{M}^0(c')$ with various $c'$ thanks to this formula.

Note that if $(c_1, [C]) \geq 0$, we have

$$\dim \hat{M}^0\left(c - \sum_{n} j_n e_n\right)$$
\begin{equation}
\dim \hat{M}^m(c) - \sum r(2n+1)j_n - \sum j_n \left( \sum j_n + 2(c_1, [C]) \right) < \dim \hat{M}^m(c)
\end{equation}
if \((j_1, j_2, \ldots) \neq 0\).

1.5.2.
We usually consider the moduli space \(\hat{M}(c)\) with \(0 \leq (c_1, [C]) < r\). This is always achieved by tensoring a power of the line bundle \(O(C)\). And then we can hope to relate \(\int_{\hat{M}(c)} \Phi(\mathcal{E})\) to \(\int_{M(p_*(c))} \Phi(\mathcal{E})\) thanks to Proposition 1.2. But look at (1.6). The right-hand side of (1.6) contains integrals over \(\hat{M}^0(c')\) for which we have \(0 \leq (c_1(c'), [C])\) but not necessarily less than \(r\). Thus we need to tensor a line bundle again.

Since keeping track of the precise form of the formula is rather tiresome work, we redefine a term in the right-hand side of (1.6) as \(\int_{\hat{M}^0(c)} \Phi(\mathcal{E})\) and start from it. We can assume \((c_1, [C]) \geq 0\), as we explained.

1.5.3.
First, consider the case \((c_1, [C]) = 0\). We have an isomorphism \(\Pi: \hat{M}^0(c) \cong M(p_*(c))\) by \((E, \Phi) \mapsto (p_*(E), \Phi)\), where the higher direct image sheaves \(R^{>0}p_*\mathcal{E}\) vanish. Moreover, its inverse is given by \((F, \Phi) \mapsto (p^*F, \Phi)\), and \(L^{<0}p^*F = 0\) (see [21, Proposition 3.3, Section 1]). If we denote the universal sheaf for \(M(p_*(c))\) by \(\mathcal{F}\), the universal sheaf \(\mathcal{E}\) for \(\hat{M}^0(c)\) is equal to \((p \times \Pi)^*\mathcal{F}\). Therefore we have
\[
\int_{\hat{M}^0(c)} \Phi(\mathcal{E}) = \int_{\hat{M}^0(c)} \Phi((p \times \Pi)^*\mathcal{F}).
\]
Since \(L^{<0}(p \times \Pi)^*\mathcal{F}\) vanishes, this holds in the level of \(K\)-group.

We may have expressions \(O(C)\) or \([C]\) which do not come from \(M(p_*(c))\) in the expression \(\Phi(\mathcal{E})\), but we can use the projection formula to rewrite the right-hand side as
\[
\int_{M(p_*(c))} \Phi'(\mathcal{F})
\]
for a possibly different cohomology class \(\Phi'(\bullet)\).

1.5.4.
Now we may assume \((c_1, [C]) > 0\). We have
\begin{equation}
\int_{\hat{M}^0(c)} \Phi(\mathcal{E}) = \int_{\hat{M}^1(c|C)} \Phi(\mathcal{E}(-C))
\end{equation}
by the isomorphism \(\hat{M}^0(c) \ni (E, \Phi) \mapsto (E(C), \Phi) \in \hat{M}^1(c|C)\). Two universal sheaves for \(\hat{M}^0(c)\), \(\hat{M}^1(c|C)\) are denoted by the same notation, but the latter is twisted by \(O(C)\) from the former under this isomorphism, and it is the reason why we have \(\Phi(\mathcal{E}(-C))\).
We have \(-r < (c_1(\mathcal{E}[C]), [C]) = (c_1, [C]) - r\). If this is negative, in other words, if we have \((c_1, [C]) < r\), we go to the step which will be explained in Section 1.5.5. So we assume \((c_1(\mathcal{E}[C]), [C]) \geq 0\). We now redefine the right-hand side of (1.8) as \(\int_{\hat{M}^1(c)} \Phi(\mathcal{E})\) and return back to Section 1.5.1 to apply (1.6) with \(m = 1\).

We repeat this procedure until all terms are integrals over \(\hat{M}^1(c')\) with \(-r < (c_1(c'), [C]) < 0\) or \(\hat{M}^0(c'')\) with \(c_1(c'') = 0\). From the dimension estimate (1.7), the procedure ends after finite steps.

For \(\Phi(\mathcal{E}) = \prod_{f=1}^{N_f} e(\mathcal{V}_a(\mathcal{E}) \otimes e^{m_f})\), this process requires care since \(\mathcal{V}_a(\mathcal{E}(-C)) = R^1q_2^*(\mathcal{E}(-C) \otimes q_1^*(\mathcal{O}(aC - \ell_\infty))\) may not be a vector bundle on \(\hat{M}^0(c)\), so \(e(\mathcal{V}_a(\mathcal{E}(C)) \otimes e^{m_f})\) does not make sense, and we cannot apply (1.6) with \(m = 1\).

We overcome this difficulty by replacing \(e(\mathcal{V}_a(\mathcal{E}(C)) \otimes e^{m_f})\) by a product of \(e(\mathcal{V}_a(\mathcal{E}) \otimes e^{m_f})\) and a certain class, which is well defined on \(\hat{M}^0(c)\) (see the proof of Theorem 2.1 for details).

1.5.5.

Now we redefine the right-hand side of (1.8) as \(\int_{\hat{M}^1(c)} \Phi(\mathcal{E})\) and consider it under the assumption \(-r < (c_1, [C]) < 0\).

Let \(n := -(c_1, [C])\). By Proposition 1.2, we have

\[
\int_{\hat{M}^1(c)} \Phi(\mathcal{E}) = \int_{\tilde{N}(c,n)} \Phi((\text{id}_{\mathbb{P}^2} \times f_1)^*\mathcal{E})
= \int_{\tilde{N}(c,n)} \Phi((\text{id}_{\mathbb{P}^2} \times f_2)^*\mathcal{E}) \oplus C_0 \boxtimes S),
\]

where we denote the universal bundle over \(\hat{M}^1(c - ne_0)\) by \(\mathcal{E}\) for brevity. Since \(f_2: \tilde{N}(c,n) \rightarrow \hat{M}^1(c - ne_0)\) is the Grassmann bundle of \(n\)-planes in \(\text{Ext}^1_{\mathbb{P}^2}(C_0, \mathcal{E})\), we can push forward to \(\hat{M}^1(c - ne_0)\) to get

\[
\int_{\tilde{N}(c,n)} \Phi((\text{id}_{\mathbb{P}^2} \times f_2)^*\mathcal{E} \oplus C_0 \boxtimes S) = \int_{\hat{M}^1(c - ne_0)} \Phi(\mathcal{E}),
\]

where

\[
\Phi(\bullet) := \int_{\text{Gr}(n,r)} \Phi(\bullet \oplus (C_0 \boxtimes S)) \bigg| _{c(\mathbb{C}^r) = c(\text{Ext}^1_{\mathbb{P}^2}(C_0, \mathcal{E}))}.
\]

We need to explain the notation. We consider the Grassmannian \(\text{Gr}(n, r)\) of \(n\)-planes in \(\mathbb{C}^r\), and \(\int_{\text{Gr}(r - n, r)}\) is the pushforward \(H^*_{\text{GL}(r)}(\text{Gr}(r - n, r)) \rightarrow H^*_{\text{GL}(r)}(\text{pt})\). The \(\bullet\) is a variable living in the \(K\)-group \(K(\mathbb{P}^2 \times \text{pt})\). The universal subbundle of the trivial bundle \(\mathbb{C}^r\) is denoted by \(S\), and \(C_0 \boxtimes S\) is a sheaf on \(\mathbb{P}^2 \times \text{Gr}(r, n)\). We consider \(\text{Gr}(r, n)\) as a moduli space and \(\bullet \oplus C_0 \boxtimes S\) as a universal sheaf, and we apply the function \(\Phi\). Finally, \((\cdot)|_{c(\mathbb{C}^r) = c(\text{Ext}^1_{\mathbb{P}^2}(C_0, \mathcal{E}))}\) means that we substitute the Chern classes of \(\text{Ext}^1_{\mathbb{P}^2}(C_0, \mathcal{E})\) to the equivariant Chern classes of \(\mathbb{C}^r\) in \(H^*_{\text{GL}(r)}(\text{pt})\).

We now redefine \(\int_{\hat{M}^1(c)} \Phi(\mathcal{E})\) as \(\int_{\hat{M}^1(c - ne_0)} \Phi(\mathcal{E})\) and return to Section 1.5.1. Since \(\dim \hat{M}^1(c - ne_0) < \dim \hat{M}^1(c)\), this procedure eventually stops.
1.6. Example
Consider the case $c \in H^r(\mathbb{P}^2)$ with $r(c) = r$, $c_1(c) = 0$, $(\Delta(c), [\mathbb{P}^2]) = 1$. In Theorem 1.5 the wall-crossing term appears only in the case $m = 0$, $j = 0$. Therefore

$$\int_{\mathcal{M}} \Phi(\mathcal{E}) - \int_{\mathcal{M}_0} \Phi(\mathcal{E})$$

(1.9)

$$= \int_{\mathcal{M}_0(c-e_0)} \text{Res}_{h_1=0} e(\mathcal{N}(\mathcal{E}_0, C_0) \otimes e^{-h_1}) e(\mathcal{N}(\mathcal{E}_0, \mathcal{E}_0) \otimes e^{h_1}).$$

In the quiver description Theorem 4.2 for $\mathcal{M}_0(c-e_0)$, we have $V_0 = \mathbb{C}$, $V_1 = 0$, and hence

$$\mathcal{M}_0(c-e_0) \cong \mathbb{P}^{r-1}.$$ 

This also follows from Proposition 1.2. In fact, $f_1$ is an isomorphism in this case. We also see that $\mathcal{E}_0 \cong \text{Ker}[\mathcal{O}_\mathbb{P}^{gr} \to \mathcal{O}_\mathbb{P}(1) \otimes \mathcal{O}_C]$. Then we have

$$\mathcal{N}(\mathcal{E}_0, C_0) \cong \mathcal{O}_\mathbb{P}(-1), \quad \mathcal{N}(\mathcal{C}, \mathcal{E}_0) \cong \mathcal{O}_\mathbb{P}(1)^{\oplus 2} \oplus S,$$

where $\mathcal{O}_\mathbb{P}(1)$ is the hyperplane bundle of $\mathbb{P} = \mathbb{P}^{r-1}$ and $S$ is the universal subbundle, that is, kernel, of $\mathcal{O}_\mathbb{P}^{gr} \to \mathcal{O}_\mathbb{P}(1)$. This also follows from Lemmas 4.9 and 4.11. Therefore

$$e(\mathcal{N}(\mathcal{E}_0, C_0) \otimes e^{-h_1}) = -c_1(\mathcal{O}_\mathbb{P}(1)) + h_1,$$

$$e(\mathcal{N}(\mathcal{C}, \mathcal{E}_0) \otimes e^{h_1}) = (c_1(\mathcal{O}_\mathbb{P}(1)) + h_1)^2 e(S \otimes e^{h_1}) = h_1^2(c_1(\mathcal{O}_\mathbb{P}(1)) + h_1).$$

For $\Phi$, we consider a simplest nontrivial case. Let $\mu(C)$ be the cohomology class on $\mathcal{M}(c)$ given by

(1.10)

$$\mu(C) := \Delta(\mathcal{E})/[C],$$

where $/$ denotes the slant product $/: H^d_T(\mathbb{P}^2 \times \mathcal{M}(c)) \otimes H^i_T(\mathbb{P}^2) \to H^{d-i}(\mathcal{M}(c))$. This is the $\mu$-map appearing in the usual Donaldson invariants. We have

$$\Delta(\mathcal{E}_0 \oplus C_0 \otimes e^{-h_1})/[C] = -c_1(\mathcal{O}_\mathbb{P}(1)) - h_1 + \varepsilon_1 + \varepsilon_2,$$

where $\varepsilon_1$, $\varepsilon_2$ are generators of Lie($\mathbb{C}^* \times \mathbb{C}^*$) corresponding to $t_1$, $t_2$.

We also have

$$\mathcal{V}_1(\mathcal{E}_0 \oplus C_0 \otimes e^{-h_1}) \cong e^{-h_1}.$$ 

Hence

$$\prod_{f=1}^{N_f} e(\mathcal{V}_1(\mathcal{E}_0 \oplus C_0 \otimes e^{-h_1}) \otimes e^{m_f}) = \prod_{f=1}^{N_f} (m_f - h_1).$$

We assume $2r - N_f \geq 1$ and take $\Phi(\mathcal{E}) = \mu(C)^{2r-N_f} \prod_{f=1}^{N_f} e(\mathcal{V}_1(\mathcal{E}) \otimes e^{m_f}).$ Then the right-hand side of (1.9) becomes

$$\int_{\mathbb{P}^{r-1}} \text{Res}_{h_1=0} \frac{(-c_1(\mathcal{O}_\mathbb{P}(1)) - h_1 + \varepsilon_1 + \varepsilon_2)^{2r-N_f} \prod_{f=1}^{N_f} (m_f - h_1)}{h_1^2(c_1(\mathcal{O}_\mathbb{P}(1)) + h_1)^2}. $$
By the degree reason, this must be a constant in $\varepsilon_1, \varepsilon_2, m_f$. Therefore we may set all zeros. Then this is equal to

$$-\int_{\mathcal{P}} \text{Res} h_1^{N_f-r} (c_1(\mathcal{O}_{\mathcal{P}}(1)) + h_1)^{2r-N_f-2}$$

$$= -\left( \frac{2r-N_f-2}{r-1} \right).$$

If $r = 2, N_f = 0$, the answer is $-2$. This is a simplest case of the blow-up formula, which was used to define Donaldson invariants for $c_2$ in the unstable range.

2. Applications: Vanishing theorems

As we mentioned above, the wall-crossing formula gives us only a recursive procedure to give the blow-up formula. In this section, we concentrate on a rather special $\Phi(\mathcal{E})$ and derive certain vanishing theorems. They turn out to be enough for applications to the instanton counting.

2.1. Theory with matters

Let $\mu(C)$ be as in (1.10). We consider

$$\Phi(\mathcal{E}) = \prod_{f=1}^{N_f} e(\mathcal{V}_0(\mathcal{E}) \otimes e^{m_f}) \times \exp(t\mu(C))$$

and study the coefficient $\Phi_d(\mathcal{E})$ of $t^d$ with small $d$. We assume $N_f \leq 2r$ hereafter.

**Theorem 2.1**

Suppose $(c_1, [C]) = 0$. Then

$$\int_{\overline{M}^{\text{virt}}(c)} \Phi(\mathcal{E}) = \int_{M(p\ast(c))} \prod_{f=1}^{N_f} e(\mathcal{V}(\mathcal{E}) \otimes e^{m_f}) + O(t^k),$$

where $k = \max(r+1, 2r-N_f)$. Here $\mathcal{V}(\mathcal{E}) = R^1 q_{2\ast}(\mathcal{E} \otimes q_1^\ast(\mathcal{O}(-\ell_\infty)))$ is defined from the universal sheaf $\mathcal{E}$ on $\mathbb{P}^2 \times M(p\ast(c))$ as in the case of $\mathcal{V}_0(\mathcal{E}), \mathcal{V}_1(\mathcal{E})$.

This, in particular, means that $\Phi_d(\mathcal{E}) = 0$ for $d = 1, \ldots, k-1$. When $N_f = 0$, this vanishing was shown in [19, Section 6] by the dimension counting argument. The key point was that $\dim M(c) = 2r\Delta$, and hence the smaller moduli spaces have codimension greater than or equal to $2r$. Once the wall-crossing formula is established as in Section 1, the remaining argument below is similar, and the bound $2r-N_f$ comes from the fact that the virtual fundamental class $\prod_{f=1}^{N_f} e(\mathcal{V}(\mathcal{E}) \otimes e^{m_f}) \cap [M(p\ast(c))]$ has dimension $(2r-N_f)\Delta$.

**Proof**

Let us compute the cohomological degrees of both sides of the equality in Theorem 1.5, where we say that $\int_{\overline{M}^{\text{virt}}(c)} \wedge$ has degree $k$ if it is contained in
\[ H_{2k}^\mathbb{F}(M_0(p_*(c))). \] We have

\[
\deg \int_{\tilde{M}^{m+1}(c)} \Phi_d(\mathcal{E}) = \deg \int_{\tilde{M}^m(c)} \Phi_d(\mathcal{E}) = \dim \tilde{M}^m(c) - N_f \dim V_0(c) - d = -(2r - N_f)(\text{ch}_2(c), \tilde{\mathbb{P}^2}) - d.
\]

On the other hand, we can write

\[
\int_{\tilde{M}^m(c-je_m)} \Phi(\mathcal{E}_\phi \oplus \bigoplus_{i=1}^3 C_n \otimes e^{h_i}) \Psi^i(\mathcal{E}_\phi) = \int_{\tilde{M}^m(c-je_m)} \prod_{i=1}^{N_f} e(V_0(\mathcal{E}_\phi) \otimes e^{m_f}) \cup \forall
\]

for some cohomology class \( \forall \). Therefore its degree is at most

\[
\dim \tilde{M}^m(c-je_m) - N_f \dim V_0(c-je_m) = -(2r - N_f)(\text{ch}_2(c), \tilde{\mathbb{P}^2}) - j(m(2r - N_f) + r + j).
\]

Since \( j(m(2r - N_f) + r + j) \geq r + 1 \), it is zero if \( d \leq r \).

To prove the vanishing for \( d \leq 2r - N_f - 1 \), we need a refinement of the general machinery in Section 1.5. We need to look at each step in the flow chart (Figure 1) more closely.

The first step (see Section 1.5) has no problem. In (1.6) we have

\[
\Phi(\mathcal{E}_\phi \oplus \bigoplus_{n=0}^{m-1} \bigoplus_{i=1}^{j_n} C_n \otimes e^{h_i^{n,1}}) = \Phi(\mathcal{E}_\phi) \prod_{n=0}^{m-1} \prod_{i=1}^{j_n} \Phi(C_n \otimes e^{h_i^{n,1}})
\]

as we have a decomposition of a vector bundle \( \mathcal{V}_0(\mathcal{E} \oplus \bigoplus_{n=0}^{m-1} \bigoplus_{i=1}^{j_n} C_n \otimes e^{h_i^{n,1}}) = \mathcal{V}_0(\mathcal{E} \oplus \bigoplus_{n=0}^{m-1} \bigoplus_{i=1}^{j_n} \mathcal{V}_0(C_n \otimes e^{h_i^{n,1}}) \), and the Euler class has a multiplicative with respect to the Whitney sum.

In Sections 1.5.4 and 1.5.5 we consider the tensor product \( \mathcal{E}(\mathcal{C} - \ell) \), where \( \mathcal{E} \) is the universal family on the moduli space of 1-stable sheaves. This causes trouble because \( R^1q_{2*}(\mathcal{E}(\mathcal{C} - \ell)) \) is not a vector bundle, as mentioned earlier. We need a closer look.

By [22, Lemma 7.3], the natural homomorphism \( H^1(E(-\ell)) \to H^1(E(\mathcal{C} - \ell)) \) is surjective for a zero-stable framed sheaf \((E, \Phi)\). Therefore \( H^1(E(-\mathcal{C} - \ell)) \to H^1(E(-\ell)) \) is surjective for a 1-stable framed sheaf \((E, \Phi)\). Let us give a direct proof since we need to understand the kernel. Suppose that \( E \) is 1-stable. Since \( \text{Hom}(E, \mathcal{O}_\mathcal{C}(-2)) = 0 \), we have \( E \otimes \mathcal{O}_\mathcal{C}/\text{torsion} = \bigoplus \mathcal{O}_\mathcal{C}(\alpha_i) \) with \( \alpha_i \geq -1 \). Therefore \( H^1(E \otimes \mathcal{O}_\mathcal{C}) = 0 \). Since we have an exact sequence \( 0 = H^2(\text{Tors}_1(E, \mathcal{O}_\mathcal{C})) \to H^1(E \otimes \mathcal{L} \mathcal{O}_\mathcal{C}) \to H^1(E \otimes \mathcal{O}_\mathcal{C}) \), it implies \( H^1(E \otimes \mathcal{L} \mathcal{O}_\mathcal{C}) = 0 \), and hence \( H^1(E(-\mathcal{C} - \ell)) \to H^1(E(-\ell)) \) is surjective.

Since the kernel of this surjective homomorphism is \( H^0(E \otimes \mathcal{L} \mathcal{O}_\mathcal{C}) \), we have

\[
e(V_0(\mathcal{E}(\mathcal{C})) \otimes e^{m_f}) = e(V_0(\mathcal{E}) \otimes e^{m_f}) e(q_{2*}(\mathcal{E} \otimes \mathcal{L} \mathcal{O}_\mathcal{C}) \otimes e^{m_f}) = e(V_0(\mathcal{E}) \otimes e^{m_f}) e_{\alpha}(q_{2*}([\mathcal{E}] \otimes [\mathcal{O}_{\mathcal{C}}]) \otimes e^{m_f})
\]
on $\widehat{M}^1(c)$, where $a = \dim H^1(E(-C - \ell_{\infty})) - \dim H^1(E(-\ell_{\infty})) = (c_1(E), [C]) + r$ and we replace $\mathcal{E}$, $\mathcal{O}_C$, $q_{2*}$ by their $K$-theory classes and the $K$-theory pushforward in the last expression.
Now $\mathcal{V}_0(\mathcal{E})$ is a vector bundle over $\hat{M}^0(c)$, $\hat{M}^1(c)$ and master spaces from the quiver description in Section 4. Therefore $e(\mathcal{V}_0(\mathcal{E}) \otimes e^{m_f})$ (and also $c_0(\mathcal{Q}_2 ((\mathcal{E}) \otimes [\mathcal{O}_C]) \otimes e^{m_f})$) are well defined, so we replace $e(\mathcal{V}_0(\mathcal{E}(-C)) \otimes e^{m_f})$ by the right-hand side and continue the flow in Figure 1. We may still need to treat $\otimes \mathcal{O}(C)$ in a subsequent process in the flow chart. Then we again get $e(\mathcal{V}_0(\mathcal{E}(-C)) \otimes e^{m_f})$, so use the same procedure to replace by the right-hand side.

As a result we can write

$$\int_{\hat{M}^m(c)} \Phi_d(\mathcal{E}) = \sum_3 \int_{\hat{M}^0(c-c^3)}^{N_f} \prod_{f=1}^{N_f} e(\mathcal{V}_0(\mathcal{E}_f) \otimes e^{m_f}) \Omega_d^3(\mathcal{E}_f)$$

for various $c^3$ with $c_1(c-c^3) = 0$ and cohomology classes $\Omega_d^3(\mathcal{E}_f)$. The left-hand side has degree as in (2.2). On the other hand, the degree of the right-hand side is at most

$$\dim M(p_*(c-c^3)) - N_f \operatorname{rank} \mathcal{V}_0(\mathcal{E}_f) = (2r - N_f)(\Delta(c-c^3), [\mathbb{P}^2]) .$$

If $c^3$ is nonzero, then it is at most $(2r - N_f)(\Delta(c-c^3), [\mathbb{P}^2]) = 1$ since $(\Delta(c-c^3), [\mathbb{P}^2])$ is an integer and we have (1.7). Therefore there is no contribution to the wall-crossing formula if $d < 2r - N_f$. For $c^3 = 0$, we get $\int_{\hat{M}^0(c)} \Phi_d(\mathcal{E})$, but it is equal to $\delta_{d0} \int_{M(p_*(c))} \prod_{f=1}^{N_f} e(\mathcal{V}(\mathcal{E}) \otimes e^{m_f})$ as $\hat{M}^0(c) \rightarrow M(p_*(c))$ is an isomorphism and $\mu(C) = 0$ on $\hat{M}^0(c)$.

For a slightly modified version

$$\Phi'(\mathcal{E}) = \prod_{f=1}^{N_f} e(\mathcal{V}_1(\mathcal{E}) \otimes e^{m_f}) \times \exp(t\mu(C)) ,$$

the second part of the argument works; we get the following.

**THEOREM 2.4**

Suppose $(c_1, [C]) = 0$. Then

$$\int_{\hat{M}^m(c)} \Phi'(\mathcal{E}) = \int_{M(p_*(c))} \prod_{f=1}^{N_f} e(\mathcal{V}(\mathcal{E}) \otimes e^{m_f}) + O(t^{2r-N_f}) .$$

Moreover, the coefficient of $t^{2r-N_f}$ is

$$\left(2r - N_f - 2\right) \int_{M(p_*(c) + pt)} \prod_{f=1}^{N_f} e(\mathcal{V}(\mathcal{E}) \otimes e^{m_f})$$

if $N_f < 2r$.

For the last assertion, it is enough to calculate the case $(\Delta(c), [\mathbb{P}^2]) = 1$ by the same argument (see the proof of Theorem 2.6 for more detail). Hence Section 1.6 gives us the answer.

Next, consider the case $c_1 \neq 0$.
\textbf{THEOREM 2.5}

Suppose $0 < n := (c_1, [C]) < r$. Then

$$
\int_{\tilde{M}^m(c)} \Phi' (\mathcal{E}) = O(t^{n(r-n)}).
$$

In fact, we have

$$
\deg \int_{\tilde{M}^m(c)} \Phi'_d (\mathcal{E}) = (2r - N_f) \dim V_1(c) + n(r - n) - d,
$$

and all terms in the right-hand side of (2.3) have degrees at most $(2r - N_f) \dim V_1(c)$ as $\dim V_1(c - c^3) \leq \dim V_1(c)$. So the same argument works.

Let us state what we observed in the above proof as a general structure theorem. Let $\Phi (\mathcal{E})$ be a multiplicative class in the universal family $\mathcal{E}$. Then we have the following.

\textbf{THEOREM 2.6}

Let us fix $c_1$ with $0 \leq -(c_1, [C]) < r$. There exists a class $\Omega_j (\mathcal{E}, t)$, which is a polynomial in $c_1 (\mathcal{E})/ [0]$ ($i = 2, \ldots, r$) with coefficients in $H^\ast_{\mathcal{C}^r \times \mathcal{C}^r} (\text{pt})[[t]] = \mathbb{C}[\varepsilon_1, \varepsilon_2][[t]]$ and independent of $\Delta (c)$ such that

$$
(2.7) \quad \int_{\tilde{M}(c)} \Phi (\mathcal{E}) \exp (t \mu (C)) = \sum_{j \geq 0} \int_{M(p_\ast (c) + j \text{ pt})} \Phi (\mathcal{E}) \Omega_j (\mathcal{E}, t).
$$

Moreover, $\Omega_j (\mathcal{E}, t)$ is unique if $\Phi (\mathcal{E}) \neq 0$ for $H^\ast_T (M(r, 0, 0)) = H^\ast_T (\text{pt}) = S(\tilde{T})$.

For the theory with matters, the coefficients of $\Omega_j (\mathcal{E}, t)$ are in

$$
H^\ast_{\mathcal{C}^r \times \mathcal{C}^r \times (\mathcal{C}^r)^N_f} (\text{pt})[[t]] = \mathbb{C}[\varepsilon_1, \varepsilon_2, m_1, \ldots, m_{N_f}][[t]].
$$

\textbf{Proof}

As in the derivation of (2.3), we obtain a formula as above, where $M(p_\ast (c) + j \text{ pt})$ is replaced by $\tilde{M}_0^0 (p^\ast (p_\ast (c) + j \text{ pt}))$ and $\Omega_j (\mathcal{E}, t)$ is a polynomial in Chern classes of $q_2 (\mathcal{E} \otimes [\mathcal{O}_C (m)])$, $q_2^\ast ([\mathcal{E}]^\vee \otimes [\mathcal{O}_C (m)])$ of various $m$. This $\Omega_j (\mathcal{E}, t)$ is independent of $\Delta (c)$, as

- $\Psi^j (\mathcal{E}_0)$ in Theorem 1.5 depends only on $j$,
- the choice, whether we perform twist by $\mathcal{O} (C)$ or not, is determined by $c_1$, and
- the Grassmannian in Proposition 1.2 is determined by $r$ and $c_1$.

Thus it only remains to show that we can further replace $\Omega_j$ so that it is a polynomial in $c_i (\mathcal{E})/ [0]$ ($i = 2, \ldots, r$).

By the Grothendieck-Riemann-Roch theorem, these classes can be expressed by $c_i (\mathcal{E})/ [0] = c_i (q_2^\ast ([\mathcal{E}] \otimes [\mathcal{O}_C (m)]))$. Note that $q_2^\ast ([\mathcal{E}] \otimes [\mathcal{O}_C (m)]) = - \sum_{a = 0}^2 (-1)^a \times \text{Ext}^a (\mathcal{O}_C (-1), \mathcal{E})$. If we go back across the wall from $\tilde{M}_0^0$ to $\tilde{M}_1^1$, we have $\text{Ext}^0_{q_2^\ast} (\mathcal{O}_C (-1), \mathcal{E}) = 0 = \text{Ext}^2_{q_2^\ast} (\mathcal{O}_C (-1), \mathcal{E})$ on $\tilde{M}_1^1$ by the remark after Lemma 4.11. Therefore $\text{Ext}^1_{q_2^\ast} (\mathcal{O}_C (-1), \mathcal{E})$ is a vector bundle of rank $r$, and $c_i (\mathcal{E})/ [0]$ vanishes.
for \( i > r \). Since the difference of the integrals over \( \hat{M}^1 \) and \( \hat{M}^0 \) are expressed by integrals over small moduli spaces, we can eventually express \( \Omega_j \) as a polynomial in \( c_i(\mathcal{E})/\lfloor 0 \rfloor \) \((i = 2, \ldots, r)\) by a recursion.

Let us show the uniqueness of \( \Omega_j(\mathcal{E}, t) \) by a recursion on \( j \). Let us take the smallest possible \( \Delta(c) \) with \( \hat{M}(c) \neq \emptyset \), that is, the case when \( c + (c_1, [C]) e_0 = (r, 0, 0) \) (cf. Proposition 1.2). Then we have only the term with \( j = 0 \) in the right-hand side of (2.7). In this case, \( p_+(c) = (r, 0, 0) \), and the moduli space \( M(r, 0, 0) \) is a single point. Therefore \( \Omega_0(\mathcal{E}, t) \) is determined by (2.7).

Now suppose that \( \Omega_j(\mathcal{E}, t) \) with \( j < n \) are determined. Then we take \( c \) whose \( \Delta(c) \) is \( n \) larger than the previous smallest \( \Delta(c) \). Then \( j \) in the summation in (2.7) runs from zero to \( n \). Moreover, \( M(p_+(c) + n \text{ pt}) = M(r, 0, 0) \) is a single point again. Therefore \( \Omega_n(\mathcal{E}, t) \) is determined from (2.7) and \( \Omega_j(\mathcal{E}, t) \) with \( j < n \).

Suppose that the degree of \( \int_{\hat{M}(c)} \Phi(\mathcal{E}) \) is of a form \( \gamma \Delta(c) + a(c_1, [C]) + b \) for some constants \( \gamma, a, \) and \( b \), depending only on \( r \). We further assume that \( \gamma > 0 \), as in the case \( \gamma = 2r - N_f > 0 \) for the theory with matters. Then

\[
\deg \int_{\hat{M}(c)} \Phi(\mathcal{E}) \mu(C)^d = \gamma \Delta(c) + a(c_1, [C]) + b - d,
\]

\[
\deg \int_{M(p_+(c) + j \text{ pt})} \Phi(\mathcal{E}) \Omega_j(\mathcal{E}, t) \leq \gamma (\Delta(p_+(c)) - j) + b.
\]

Since we are fixing \((c_1, [C])\) as in Theorem 2.6, the two degrees cannot match if \( j \) is too large. This means that we only need to calculate finitely many \( \Omega_j(\mathcal{E}, t) \) to determine \( \int_{\hat{M}(c)} \Phi(\mathcal{E}) \mu(C)^d \) for a fixed \( d \). (In practice, the maximal \( j \) can be calculated explicitly.)

### 2.2. K-theory version

We derive the wall-crossing formula for a \( K \)-theoretic integration via the Grothendieck-Riemann-Roch formula.

Let \( \text{td}(\alpha) \) be the Todd class of a \( K \)-theory class \( \alpha \) on various moduli spaces. The Todd class of the tangent bundle \( T_M \) of a variety \( M \) is denoted by \( \text{td} M \). We have

\[
\text{td} \hat{M}^m(c) = \text{td}(\mathfrak{M}(\mathcal{E}, \mathcal{E})).
\]

For integers \( d, l, \) and \( a = 0 \) or \( 1 \), we consider

\[
(2.8) \quad \Phi(\mathcal{E}) = \text{td}(\mathfrak{M}(\mathcal{E}, \mathcal{E})) \exp \left( l c_1(V_a(\mathcal{E})) \right) \exp \left( -d \cdot ch_2(\mathcal{E})/|C| \right).
\]

By a discussion in [20, several paragraphs preceding Definition 2.1], \(- ch_2(\mathcal{E})/|C|\) is the first Chern class of an equivariant line bundle up to a (rational) cohomology class in \( H^2_F(\text{pt}) \), which is zero if \((c_1, [C]) = 0\). Since this difference is immaterial in the following discussion (in particular in Theorem 2.11), we identify \(- ch_2(\mathcal{E})/|C|\) with the equivariant line bundle, which we denote by \( \mu(C) \). (This is the same as
μ(C) in the Section 2.1 up to a class in \( H_T^2(\text{pt}) \). Then the equivariant Riemann-Roch theorem (see, e.g., [9]) we have is

\[
\int_{M^m(c)} \Phi(E) = \tau(\tilde{\pi}_*(\mu(C) \otimes \det V_c(\xi)))
\]

where \( \tau \) is the equivariant Todd homomorphism \( \tau: K^\tilde{T}(M_0(p_*(c))) \to H_T^2 \times (M_0(p_*(c))) \) for the Uhlenbeck partial compactification \( M_0(p_*(c)) \), and \( \tilde{\pi}_* \) is the pushforward homomorphism in equivariant \( K \)-theory.

We have

\[
\text{td}(\mathfrak{M}(E,E)) = \text{td}(\mathfrak{M}(E_1,E_1)) \text{td}(\mathfrak{M}(E_2,E_2)) \text{td}(\mathfrak{M}(E_1,E_2)) \text{td}(\mathfrak{M}(E_2,E_1))
\]

if \( E = E_1 \oplus E_2 \). Then from Theorem 1.5 we get

\[
\int_{M^{m+1}(c)} \Phi(E) - \int_{M^m(c)} \Phi(E)
\]

\[
= \sum_{j=1}^{\infty} \int_{M^m(c-j_m)} \Phi(E_0) \cup \text{Res}_{h_j = 0} \cdots \text{Res}_{h_1 = 0} \Psi^j(E_0),
\]

where

\[
\Psi^j(\bullet) := \frac{1}{j!} \left( \prod_{i=1}^{j} \exp \left( t c_1(V_c(C_m \otimes e^{-h_i})) - d \text{ch}_2(C_m \otimes e^{-h_i}) /[C] \right) \right).
\]

Here \( e^K \) is the (Chern character of) \( K \)-theoretic Euler class:

\[
e^K(\alpha) = e(\alpha) \text{td}(\alpha)^{-1} = \sum_{p=0}^{\infty} (-1)^p \text{ch} \left( \bigwedge^p \alpha^\vee \right),
\]

where \( e(\alpha) \) is the usual Euler class as before.

Strictly speaking, we need to consider the completion \( \mathbb{C}[h_i^{-1}, h_i] \) for the coefficient rings of the localized equivariant homology groups of moduli spaces as, for example, \( e^{-h_i} \) is not allowed. Here \( \mathbb{C}[h_i^{-1}, h_i] \) is the algebra of formal power series \( \sum a_j h^j \) such that \( \{ j \leq 0 \mid a_j \neq 0 \} \) is finite. The modification appears only at Section 6.1 and the beginning of Section 6.3, and the rest of the proof remains unchanged.

Observe that \( h_i \) appears always as a function in \( x_i := e^{-h_i} - 1 \) in the above formula. We change the coefficient ring from \( \mathbb{C}[h_i^{-1}, h_i] \) to \( \mathbb{C}[x_i^{-1}, x_i] \).

We have

\[
\text{Res}_{h_i = 0} f(e^{-h_i} - 1) = - \text{Res}_{x_i = 0} \frac{f(x_i)}{x_i + 1}
\]

as \( dx_i = -e^{-h_i} dh_i = -(x_i + 1) dh_i \). Therefore we have the following.
THEOREM 2.9

\[
\int_{\hat{M}^{m+1}(c)} \Phi(\mathcal{E}) - \int_{\hat{M}^{m}(c)} \Phi(\mathcal{E}) = \sum_{j=1}^{\infty} \int_{\hat{M}^{m}(c-je_m)} \Phi(\mathcal{E}) \cup \text{Res}_{x=0} \cdots \text{Res}_{x=0} \Psi^j(\mathcal{E}),
\]

where

\[
\Psi^j(\bullet) := \frac{1}{j!} \prod_{i=1}^{j} \frac{\exp(lc_1(\mathcal{V}_a(C_m \otimes (1 + x_i)))) - d \text{ch}_2(C_m \otimes (1 + x_i))/[C] \prod_{1 \leq i_1 \neq i_2 \leq j} \frac{x_{i_1} - x_{i_2}}{1 + x_{i_1}}}{e^{K(\mathcal{N}(C_m, \bullet) \otimes (1/(1 + x_i)))}(-(1 + x_i))}
\]

In view of Proposition 1.2 the following is useful to replace the $K$-theoretic integration on $\hat{M}^1(c)$ by one on $\hat{N}(c,n)$.

LEMMA 2.10

Consider the diagram in Proposition 1.2. We have

\[
\mathbf{R}f_1^*(\mathcal{O}\hat{N}(c,n)) = \mathcal{O}\hat{M}^1(c).
\]

Proof

Since $f_1$ is a proper birational morphism between smooth varieties, this is a well-known result (see, e.g., [11, Section 5.1]).

In the remainder of this section we study the vanishing theorem for small $d$.

THEOREM 2.11

Assume $0 \leq l \leq r$.

1. Suppose $(c_1, [\mathcal{C}]) = 0$. If $0 \leq al + d \leq r$,

\[
\int_{\hat{M}^{m}(c)} \Phi(\mathcal{E}) = \int_{M^{m}(c)} \text{td}(\mathcal{N}(\mathcal{E}, \mathcal{E})) \exp(lc_1(\mathcal{V}(\mathcal{E})))
\]

where $\mathcal{V}(\mathcal{E})$ is the vector bundle defined as in Theorem 2.1.

2. Suppose $a = 1$ and $0 < (c_1, [\mathcal{C}]) < r$. If $0 < d \leq \min(r + (c_1, [\mathcal{C}]) - l, r - 1)$,

\[
\int_{\hat{M}^{m}(c)} \Phi(\mathcal{E}) = 0.
\]

This result was conjectured in [8, (1.37), (1.43)].

Proof

We study factors of $\Psi^j(\mathcal{E})$ more closely. Note that $\mathcal{E}$ is the universal sheaf for $\hat{M}^m(c - je_m)$; hence

\[
\text{rank } \mathcal{N}(C_m, \mathcal{E}) = (m + 1)r + (c_1, [\mathcal{C}]) + j,
\]

\[
\text{rank } \mathcal{N}(\mathcal{E}, C_m) = mr + (c_1, [\mathcal{C}]) + j.
\]
If \( \{ \alpha_a \}, \{ \beta_b \} \) are Chern roots of \( \mathcal{R}(C_m, \mathcal{E}_b), \mathcal{R}(\mathcal{E}_b, C_m) \), respectively, we have

\[
\frac{1}{e^K(\mathcal{R}(C_m, \mathcal{E}_b) \otimes (1/(1 + x_i)))} = \frac{\exp(\sum_a \alpha_a)}{(-x_i)^{(m+1)r + (c_1, [C])} + j} \prod_a \frac{1}{1 + ((1 - e^{\alpha_a})/x_i)},
\]

\[
\frac{1}{e^K(\mathcal{R}(\mathcal{E}_b, C_m) \otimes (1 + x_i))} = \left(1 + \frac{1}{x_i}\right)^{mr + (c_1, [C]) + j} \prod_b \frac{1}{1 + ((1 - e^{-\beta_b})/x_i)}.
\]

On the other hand, we have

\[
\exp(lc_1(\mathcal{V}_a(C_m \otimes (1 + x_i)))) = \exp(lc_1(\mathcal{V}_a(C_m)))(1 + x_i)^{l(m+a)}
\]
as rank \( \mathcal{V}_a(C_m) = m + a \). Also,

\[
\exp(-d \text{ch}_2(C_m \otimes (1 + x_i))/[C]) = \exp(-d \text{ch}_2(C_m)/[C])(1 + x_i)^d
\]
as \( \text{ch}_1(C_m)/[C] = -1 \).

Let us expand \( \Psi^j(\mathcal{E}_b) \) into formal Laurent power series in \( x_1 \). Note that we have the remaining factor

\[
\frac{1}{(1 + x_1)} \prod_{i_2 \neq 1} \frac{x_1 - x_{i_2}}{1 + x_1} = \frac{\prod_{i_2 \neq 1}(x_1 - x_{i_2})}{(1 + x_1)^j}
\]
from \( \Psi^j(\bullet) \) in Theorem 2.9. This term can be absorbed into the second equality of (2.12) as

\[
\prod_{i_2 \neq 1}(x_1 - x_{i_2}) \left(1 + \frac{1}{x_1}\right)^{mr + (c_1, [C]) + j} = \frac{1}{x_1} \left(1 + \frac{1}{x_1}\right)^{mr + (c_1, [C])} \prod_{i_2 \neq 1} \left(1 - \frac{x_{i_2}}{x_1}\right).
\]

Note that \( mr + (c_1, [C]) \geq 0 \); hence \( (1 + 1/x_1)^{mr + (c_1, [C])} \) is a polynomial in \( x_1^{-1} \).

We also write

\[
(1 + x_1)^{l(m+a) + d} = x_1^{l(m+a) + d} \left(1 + \frac{1}{x_1}\right)^{l(m+a) + d}
\]
as a Laurent polynomial in \( x_1^{-1} \). Note that we have \( l(m + a) + d \geq la + d \geq 0 \) by our assumption. Therefore we have

\[
\Psi^j(E_b) = \frac{1}{x_1^N} f(x_1^{-1})
\]
for some formal power series \( f(x_1^{-1}) \) in \( x_1^{-1} \) with

\[
N = (m + 1)r + (c_1, [C]) + j + 1 - l(m + a) - d
= m(r - l) + (r - d) + (c_1, [C]) - la + j + 1.
\]
Since $0 \leq r - l$ and $0 \leq m$, the first term $m(r - l)$ is nonnegative. We also have $j \geq 1$. Therefore we have $N \geq 2$ if $d + la \leq r + (c_1, [C])$. This shows that there are no wall-crossing terms; that is,
\[
\int_{\tilde{M}(c)} \Phi(\mathcal{E}) = \int_{\tilde{M}^0(c)} \Phi(\mathcal{E}).
\]

If $(c_1, [C]) = 0$, we have an isomorphism $\Pi: \tilde{M}^0(c) \to M(p_*(c))$ given by $\Pi(E, \Phi) = (p_*(E), \Phi)$, $\Pi^{-1}(F, \Phi) = (p^*(F), \Phi)$ (see Section 1.5.3 for a precise statement). Therefore the tangent bundles $\mathfrak{N}(\mathcal{E}, \mathcal{E})$ for $\tilde{M}(c)$ and $M(p_*(c))$ are isomorphic to each other. Vector bundles $\mathcal{V}_0(\mathcal{E})$ for $\tilde{M}(c)$ and $M(p_*(c))$ are isomorphic to each other from the description of $\Pi$ in Section 1.5.3. We also have $c_2(\mathcal{E})/[C] = 0$. These show (1).

To show (2), we consider $\tilde{M}^0(c) \cong \tilde{M}^1(ce[C])$ given by $(E, \Phi) \mapsto (E(C), \Phi)$. Then Proposition 1.2 is applicable. We then have
\[
\int_{\tilde{M}^0(c)} \Phi(\mathcal{E}) = \int_{\tilde{M}^1(ce[C])} \text{td} (\mathfrak{N}(\mathcal{E}, \mathcal{E})) \exp(lc_1(\mathcal{V}_0(\mathcal{E}))) \exp(-d c_2(\mathcal{E}(-C))/[C]),
\]
where $\mathcal{E}$ in the right-hand side is the universal sheaf for $\tilde{M}^1(ce[C])$. As we explained in the beginning of this subsection, we may replace this integral by
\[
\tau(\pi_*(\mu(C)^{\otimes d} \otimes \det \mathcal{V}_0(\mathcal{E})^{\otimes l})).
\]

The difference between $c_2(\mathcal{E}(-C))/[C]$ and $c_2(\mathcal{E})/[C]$ is immaterial as it is a class pulled back from $M_0(p_*(c))$. By Lemma 2.10 and the projection formula, we can replace the above by the pushforward from $N(ce[C], n)$ with $n = r - (c_1, [C])$, where $\mu(C)$, $\mathcal{V}_0(\mathcal{E})$ are replaced by their pullbacks by $f_1$. From the exact sequence in Proposition 1.2(3), we have
\[
f_1^* \mathcal{V}_0(\mathcal{E}) = f_2^* \mathcal{V}_0(\mathcal{E}'),
\]
where $\mathcal{E}'$ is the universal sheaf for $\tilde{M}^0(ce[C] - ne_0)$. We also have
\[
f_1^* \mu(C) = \det \mathcal{S}
\]
up to the pullback of a line bundle from $\tilde{M}^0(ce[C] - ne_0)$ by $f_2$. Therefore it is enough to show that
\[
f_2^*(\det \mathcal{S}^{\otimes d}) = 0 \quad \text{for } 0 < d < r.
\]
Since $f_2$ is a Grassmann bundle of $n$-planes in a rank $r$ vector bundle, this vanishing is a special case of the Bott vanishing theorem [1] or a direct consequence of the Kodaira vanishing theorem.

\[\square\]

2.3. Casimir operators

We generalize the vanishing result in Section 2.2 to the case when we integrate certain $K$-theoretic classes given by universal sheaves on moduli spaces.

Let $\psi^p$ be the $p$th Adams operation (see, e.g., [5, Chapter I, Section 6]). We will use it for $p < 0$ defined by $\psi^p(x) = \psi^{-p}(x^\vee)$. For indeterminates $\bar{\tau} = (\cdots, \tau_{-2}, \tau_{-1}, \tau_1,$
\( \tau_2, \cdots \) and \( \vec{t} = (\cdots, t_{-2}, t_{-1}, t_1, t_2, \cdots) \), we consider a generalization of (2.8) with \( a = 0 \):

\[
\Phi(\mathcal{E}) = \text{td}(\mathcal{N}(\mathcal{E}, \mathcal{E})) \exp(lc_1(\mathcal{V}_0(\mathcal{E}))) - d\text{ch}_2(\mathcal{E})/[C])
\]

\[
\times \exp \left( \sum_{p \in \mathbb{Z} \setminus \{0\}} \tau_p \text{ch}(\psi^p(\mathcal{E})/[\hat{\mathbb{C}}^2]) + t_p \text{ch}(\psi^p(\mathcal{E}) \otimes \mathcal{O}_C(-1)/[\hat{\mathbb{C}}^2]) \right),
\]

where the \( K \)-theoretic slant product \( \bullet/[\hat{\mathbb{C}}^2] \) is defined by \( \bullet/[\hat{\mathbb{C}}^2] = q_2(\bullet \otimes q_1^*p^* \times (K_{C^2}^{1/2})) \) with \( p: \hat{\mathbb{C}}^2 \to \mathbb{C}^2 \). We have two remarks for the definition. First, we define the pushforward \( q_2 \) by the localization formula, that is, the sum of the fixed point contributions, since \( q_2 \) is not proper. This is a standard technique in instanton counting, and its meaning was explained in detail in [19, Section 4]. Second, \( K_{C^2}^{1/2} \) is the trivial line bundle twisted together by the square root of the character of \((\mathbb{C}^*)^2\), which we consider as a character of its double cover. Having the previous two remarks in mind, we see that the previous integral is essentially defined by the equivariant \( K \)-theory pushforward as before.

We expand \( \int_{\hat{M}^m(c)} \Phi(\mathcal{E}) \) in \( t_p, \tau_p \) and consider coefficients

\[
\int_{\hat{M}^m(c)} \Phi(\mathcal{E}) = \sum_{\vec{n}, \vec{m}} \prod_{p \neq 0} \tau_p^{n_p} t_p^{m_p} \int_{\hat{M}^m(c)} \Phi_{\vec{n}, \vec{m}}(\mathcal{E}),
\]

where \( \vec{n} = (\ldots, n_{-1}, n_1, \ldots), \vec{m} = (\ldots, m_{-1}, m_1, \ldots) \). If we set

\[
\left( \frac{\partial}{\partial \vec{t}} \right)^{\vec{n}} := \prod_{p \neq 0} \left( \frac{\partial}{\partial \tau_p} \right)^{n_p}, \quad \vec{n}! = \prod_{p \neq 0} n_p!,
\]

we have

\[
\int_{\hat{M}^m(c)} \Phi_{\vec{n}, \vec{m}}(\mathcal{E}) = \frac{1}{\vec{n}! \vec{m}!} \left. \left( \frac{\partial}{\partial \vec{t}} \right)^{\vec{n}} \left( \frac{\partial}{\partial \vec{t}} \right)^{\vec{m}} \int_{\hat{M}^m(c)} \Phi(\mathcal{E}) \right|_{\vec{t} = \vec{t} = 0}
\]

\[
= \frac{1}{\vec{n}! \vec{m}!} \int_{\hat{M}^m(c)} \text{td}(\mathcal{N}(\mathcal{E}, \mathcal{E})) \exp(lc_1(\mathcal{V}_0(\mathcal{E}))) - d\text{ch}_2(\mathcal{E})/[C])
\]

\[
\times \text{ch} \left( \bigotimes_p (\psi^p(\mathcal{E})/[\hat{\mathbb{C}}^2])^{\otimes n_p} \otimes (\psi^p(\mathcal{E}) \otimes \mathcal{O}_C(-1)/[\hat{\mathbb{C}}^2])^{\otimes m_p} \right).
\]

**Proposition 2.13**

Suppose \( (c_1, [C]) = 0 \).

1. Assume the following:
   
   (a) \( 0 \leq d + \sum_{p < 0} p m_p + p m_p \), and
   
   (b) \( d + \sum_{p > 0} p m_p + p m_p \leq r \).

Then the wall-crossing term is zero; that is,

\[
\int_{\hat{M}^m(c)} \Phi_{\vec{n}, \vec{m}}(\mathcal{E}) = \int_{\hat{M}^0(c)} \Phi_{\vec{n}, \vec{m}}(\mathcal{E}).
\]
(2) We further assume $m_p \neq 0$ for some $p$. Then

$$\int_{\widehat{M}^m(c)} \Phi_{\pi, \tilde{m}}(\mathcal{E}) = 0.$$ 

Proof

(1) We note that

$$\psi^p(\mathcal{E} \oplus C_m \otimes (1 + x_i)) = \psi^p(\mathcal{E}) + \psi^p(C_m) \otimes (1 + x_i)^p,$$

as the Adams operation is a homomorphism. Then the proof goes exactly as before.

(2) Recall that $\widehat{M}^0(c) \cong M(p_*(c))$ under $(E, \Phi) \mapsto (p_*(E), \Phi)$. Then $\psi^k(E) \otimes \mathcal{O}_C(-1)/[\mathbb{C}^2]$ vanishes since $p_*\mathcal{O}_C(-1) = 0$. □

3. Partition function and Seiberg-Witten curves

In this section we explain an application of the vanishing theorems to Nekrasov partition functions. Here a reader should be familiar with [18]–[20], and [8].

3.1. Partition function

Let us fix $l \in \mathbb{Z}$. We define a partition function as the generating function of integrals considered in Sections 2.2 and 2.3:

$$Z_{i}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \tilde{\tau}) = Z_{i}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \tilde{\tau})$$

$$:= \sum_c (\Lambda^{2r}e^{-(r+1)(\varepsilon_1+\varepsilon_2)/2}(\Delta(c),[\mathbb{P}^2]))$$

$$\times \int_{M(c)} \text{td} M(c) \exp(lc_1(\mathcal{V}(\mathcal{E}))) \exp\left(\sum_{p \in \mathbb{Z}_- \setminus \{0\}} \tau_p \text{ch}(\psi^p(\mathcal{E})/[\mathbb{C}^2])\right),$$

where the rank $r = r(c)$ is fixed. Here $\vec{a} = (a_1, \ldots, a_r)$ ($\sum a_\alpha = 0$) is the vector given by generators $a_i$ of $H_T^*(\text{pt})$ and $\varepsilon_1, \varepsilon_2$ of $H^{*,2}(\text{pt})$, and the integrals, more coefficients of monomials in $\tau_p$'s, take values in the quotient field $\mathcal{G}(\tilde{T})$ of $H_T^*(\text{pt})$ as explained in Section 1.3. (More precisely, the quotient field of the representation ring $R(\tilde{T}) = \mathbb{Z}[e^{\pm \varepsilon_1}, e^{\pm \varepsilon_2}, e^{\pm a \alpha}]$ is as in Section 2.2 since this is a $K$-theoretic partition function.) And the $K$-theoretic slant product $\bullet/[\mathbb{C}^2]$ is defined by $q_{2*}(\bullet \otimes q_1^*(K_{\mathbb{C}^2}/[\mathbb{C}^2]))$ as in Section 2.3.

We have

$$\left(\frac{\partial}{\partial \tilde{\tau}}\right)^\vec{n} Z_{i}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \tilde{\tau} = 0)$$

$$= \sum_c (\Lambda^{2r}e^{-(r+1)(\varepsilon_1+\varepsilon_2)/2}(\Delta(c),[\mathbb{P}^2]))$$

$$\times \int_{M(c)} \text{ch}\left(\bigotimes_p (\psi^p(\mathcal{E})/[\mathbb{C}^2])^{\otimes n_p}\right) \text{td} M(c) \exp(lc_1(\mathcal{V}(\mathcal{E}))).$$
Therefore $Z^\text{inst}_l(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tau)$ gives us integrals of any tensor products of various Adams operators applied to the universal sheaves.

We consider fixed points of the $\bar{T}$-action on $M(c)$ as in [19, Section 2]: they are parameterized by $r$-tuples of Young diagrams $\tilde{Y} = (Y_1, \ldots, Y_r)$ with $|\tilde{Y}| = \sum |Y_i| = (\Delta(c), [\mathbb{P}^2])$ corresponding to direct sums of monomial ideals in $\mathbb{C}[x, y]$. The character of the fiber of $\mathcal{V}(\mathcal{E})$ at the fixed point $\tilde{Y}$ is given by

$$\text{ch}(\mathcal{V}(\mathcal{E})|_{\tilde{Y}})(\varepsilon_1, \varepsilon_2, \tilde{a}) = \sum_{\alpha=1}^r a^\alpha \sum_{s \in Y_\alpha} e^{-l'(s)\varepsilon_1 - a'(s)\varepsilon_2},$$

where $a'(s)$, $l'(s)$ are as in [19, Section 2]. We have

$$\exp(lc_1(\mathcal{V}(\mathcal{E})|_{\tilde{Y}})) = \exp \left[ l \sum_{\alpha=1}^r \sum_{s \in Y_\alpha} (a_\alpha - l'(s)\varepsilon_1 - a'(s)\varepsilon_2) \right].$$

Therefore we have

$$Z^\text{inst}_l(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}) = \sum_{\tilde{Y}} \frac{\left( \frac{\Lambda^2 r e^{-r(\varepsilon_1+\varepsilon_2)/2}}{2} \right)^{|\tilde{Y}|}}{\prod_{\alpha, \beta} n^\tilde{Y}_{\alpha, \beta}(\varepsilon_1, \varepsilon_2, \tilde{a})} \times \exp \left[ l \sum_{\alpha=1}^r \sum_{s \in Y_\alpha} \left( a_\alpha - l'(s)\varepsilon_1 - a'(s)\varepsilon_2 - \frac{\varepsilon_1 + \varepsilon_2}{2} \right) \right] \times \exp \left[ \sum_{p, \alpha} \tau_p a^\alpha \left\{ 1 - (1 - e^{-p\varepsilon_1})(1 - e^{-p\varepsilon_2}) \sum_{s \in Y_\alpha} e^{-pl'(s)\varepsilon_1 - pa'(s)\varepsilon_2} \right\} \right],$$

where $n^\tilde{Y}_{\alpha, \beta}(\varepsilon_1, \varepsilon_2, \tilde{a})$ is the alternating sum of characters of exterior powers of the cotangent space of $M(r, n)$ at the fixed point $\tilde{Y}$. Its explicit formula was given in [20, Section 1.2], where it was denoted by $n^\tilde{Y}_{\alpha, \beta}(\varepsilon_1, \varepsilon_2, \tilde{a}; \beta)$, and we put $\beta = 1$.

We have

$$(3.4) \quad Z^\text{inst}_l(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}) = Z^\text{inst}_{-l}(-\varepsilon_1, -\varepsilon_2, -\tilde{a}; \Lambda, \tilde{\tau}'),$$

where $\tilde{\tau}'$ is given by $\tilde{\tau}_p = \tau_{-p}$. This symmetry is a simple consequence of [8, displayed formula one below (1.33)] or the Serre duality.

Let $d \in \mathbb{Z}_{\geq 0}$. We consider a similar partition function on the blowup:

$$Z^\text{inst}_{l,k,d}(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}, \tilde{\nu}) := \sum_c \left( \frac{\Lambda^2 r e^{-(r+1)(\varepsilon_1+\varepsilon_2)/2}}{2} \right)^{|\tilde{M}(c)|} \times \int_{\tilde{M}(c)} \text{td} \tilde{M}(c) \exp \left( lc_1(\mathcal{V}_0(\mathcal{E})) - d\text{ch}_2(\mathcal{E})/[C] \right) \times \exp \left( \sum_{p \in \mathbb{Z}\{0\}} \tau_p \text{ch}(\psi^p(\mathcal{E})/[\mathbb{C}^2]) + t_p \text{ch}(\psi^p(\mathcal{E}) \otimes O_C(-1)/[\mathbb{C}^2]) \right),$$

where we also fix $(c_1(c), [C]) = -k$ in this case.
This is related to the partition function (3.1) by

\[
\hat{Z}_{l,k,d}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \tilde{a}, \Lambda, \tilde{\tau}, \tilde{t}) = \sum_{\tilde{k} = (k_\alpha) \in \mathbb{Z}^r} \frac{(e^{(\varepsilon_1 + \varepsilon_2)(d - (r + l)/2)}A^{2r})^{2r}}{\prod_{r \in \Delta} l^k \alpha(\varepsilon_1, \varepsilon_2, \tilde{a})} \times \exp \left[ l \left( \frac{1}{6} (\varepsilon_1 + \varepsilon_2) \sum_\alpha k_\alpha^3 + \frac{1}{2} \sum_\alpha k_\alpha^2 a_\alpha \right) \right] \\
\times Z_l^{\text{inst}}(\varepsilon_1, \varepsilon_2 - \varepsilon_1, \tilde{a} + \varepsilon_1 k; \Lambda e^{d - (r + l)/2} \varepsilon_1, e^{-\varepsilon_1/2} (\tilde{\tau} + (e^{\varepsilon_1} - 1) \tilde{t})) \\
\times Z_l^{\text{inst}}(\varepsilon_1 - \varepsilon_2, \varepsilon_2, \tilde{a} + \varepsilon_2 k; \Lambda e^{d - (r + l)/2} \varepsilon_2, e^{-\varepsilon_2/2} (\tilde{\tau} + (e^{\varepsilon_2} - 1) \tilde{t}))
\]

where \(l^k \alpha(\varepsilon_1, \varepsilon_2, \tilde{a})\) is a function given in [20, (2.3)].

Let us briefly explain how this formula is proved. It is a consequence of the Atiyah-Bott-Berline-Vergne fixed point formula applied to the \(\tilde{C}\)-action on \(\tilde{M}(e)\). The fixed points are parameterized by \((\tilde{k}, \tilde{Y}^1, \tilde{Y}^2)\), where \(\tilde{k} \in \mathbb{Z}^r\) corresponds to a line bundle \(\mathcal{O}(k_\alpha C)\), and \(\tilde{Y}^1, \tilde{Y}^2\) are Young diagrams corresponding to monomial ideals in the toric coordinates at the \((\mathbb{C}^* \times \mathbb{C}^*)\)-fixed points \(p_1 = ([1 : 0 : 0], [1 : 0])\) and \(p_2 = ([1 : 0 : 0], [0 : 1])\) in \(\mathbb{P}^2\) (see [19, Section 3] for more details). The structure of the above formula, that is, the sum over \(\tilde{k}\) of the product of two partition functions, comes from this description of the fixed point set. The shift of variables in the partition functions comes from the study of tangent bundles, universal sheaves at fixed points. All of these are done in [19, Section 3] and [8, Section 1.7], except that the expression \(e^{-\varepsilon_a/2} (\tilde{\tau} + (e^{\varepsilon_a} - 1) \tilde{t})\) \((a = 1, 2)\) appears for variables for the Adams operators.

If we replace the Adams operator \(\psi^p\) by the degree \(p\) part of the Chern character, the expression was given in [18, Section 4], where we just need to change variables as \(\tilde{\tau} + \varepsilon_a \tilde{t}\). In our situation, \(\tilde{t}\) is multiplied by \(\text{ch} (\mathcal{O}_C (-1))|_{p_a} = e^{\varepsilon_a} - 1\) instead of \(\varepsilon_a\). The factor \(e^{-\varepsilon_a/2}\) appears as the ‘square root’ of \(K_{\mathcal{C}^2} \otimes K_{\tilde{\mathcal{C}}^2}^{-1}\) at the fixed point \(p_a\), since the \(K\)-theoretic slant product \(\bullet / [\tilde{\mathcal{C}}^2]\) was defined as \(q_{2*}(\bullet \otimes q_1^* p^* (K_{\mathcal{C}^2}^{1/2}))\), not as \(q_{2*}(\bullet \otimes q_1^* K_{\tilde{\mathcal{C}}^2}^{1/2})\). (We avoid \(K_{\tilde{\mathcal{C}}^2}^{1/2}\), which cannot be defined.)

We have

\[
\hat{Z}_{l,k,d}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau} = 0, \tilde{t}) = \hat{Z}_{l,k,r-d}^{\text{inst}}(\varepsilon_1, \varepsilon_2, -\tilde{a}; \Lambda, \tilde{\tau} = 0, -\tilde{t})
\]

This is proved exactly as in [8, Section 1.7.1, last displayed formula] and (3.4), or the Serre duality.

We define the perturbation part (see [20, Section 4.2], [8, Section 1.7.2] for more details). We set

\[
\gamma_{\varepsilon_1, \varepsilon_2}(x; \Lambda) := \frac{1}{2 \varepsilon_1 \varepsilon_2} \left( -\frac{1}{6} \left( x + \frac{1}{2} (\varepsilon_1 + \varepsilon_2) \right)^3 + x^2 \log \Lambda \right)
\]
We do not make precise to which ring the full partition functions belong as a

where

We shift from the previous

comes from

for \((x, \Lambda)\) in a neighborhood of \(\sqrt{-1}\mathbb{R}_0 \times \mathbb{R}_0\).

We define the full partition function by

Using the difference equation satisfied by the perturbation terms (see [20, Section 4.2], [8, Section 1.7.2]), we can absorb the factors in (3.5) coming from \((3.6)\) into the partition function to get

\[
\begin{aligned}
\widetilde{Z}_{l,k,d}(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}, \tilde{t}) &= \exp \left[ - \sum_{\alpha \neq \beta} \tilde{\gamma}_{\varepsilon_1, \varepsilon_2}(a_{\alpha} - a_{\beta}; \Lambda) - l \sum_{\alpha=1}^{r} \frac{a_{\alpha}^3}{6\varepsilon_1 \varepsilon_2} \right] \widetilde{Z}_{l}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}), \\
&= \exp \left[ - \sum_{\alpha \neq \beta} \tilde{\gamma}_{\varepsilon_1, \varepsilon_2}(a_{\alpha} - a_{\beta}; \Lambda) - l \sum_{\alpha=1}^{r} \frac{a_{\alpha}^3}{6\varepsilon_1 \varepsilon_2} \right] \widetilde{Z}_{l,k,d}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \tilde{a}; \Lambda, \tilde{\tau}, \tilde{t}).
\end{aligned}
\]

(3.6)

where \(\tilde{t}\) runs over the set \(\{ \tilde{t} = (l_{\alpha})_{\alpha=1}^{r} \in \mathbb{Q}^r \mid \sum l_{\alpha} = 0, l_{\alpha} \equiv -k/r \mod \mathbb{Z}\}\), and \(e^{k_{e_a}/r} \star \tilde{\tau}\) is defined as

\[
e^{k_{e_a}/r} \star \tilde{\tau} = (\ldots, e^{-2k_{e_a}/r}(\tau_{-2}), e^{-k_{e_a}/r}(\tau_{-1}), e^{k_{e_a}/r}(\tau_1), e^{2k_{e_a}/r}(\tau_2), \ldots).
\]

We shift from the previous \(\tilde{t}\) to \(\tilde{t}\) by \(l_{\alpha} = k_{\alpha} - k/r\). The effect of this shift was calculated in [8, (1.36)] when \(\tilde{\tau} = \tilde{t} = 0\), and we have used it here. And \(e^{k_{e_a}/r} \star \tilde{\tau}\) comes from \(O(k_{e_a}C) = O((l_{\alpha} + k/r)C)\). The part \(l_{\alpha}\) is absorbed into the shift \(\tilde{a} + \varepsilon_{a}\tilde{t}\), but we need the remaining contribution from \(k/r\).

**Remark 3.7**

We do not make precise to which ring the full partition functions belong as a
function in $\Lambda$. We just use them formally to make a formula shorter as above. This applies to all formulas below until they (more precisely, their leading coefficients) are identified with one defined via Seiberg-Witten curves, which are really functions defined over an appropriate open set in $\Lambda$.

3.2. Regularity at $\varepsilon_1 = \varepsilon_2 = 0$

We assume $0 \leq l \leq r$ hereafter.

Theorem 2.11(1) means

$$\hat{Z}_{l,0,d}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0, \vec{t} = 0) = Z_l(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0)$$

for $0 \leq d \leq r$. This was conjectured in [8, (1.37)]. Combined with (3.5), we see that coefficients of $\hat{Z}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0)$ in $\Lambda^n$ are determined recursively if the above holds two different values of $d$, as explained in [18, Section 5.2]. The equation (3.8), with the left-hand side replaced by (3.6), is called the blow-up equation. It gives a strong constraint on the partition function $Z(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0)$.

As an application, in [8, Proposition 1.38] we proved the following under [8, (1.37)]:

$$Z_l^{\text{inst}}(\varepsilon_1, -2\varepsilon_1, \vec{a}; \Lambda, \vec{\tau} = 0) = Z_l^{\text{inst}}(2\varepsilon_1, -\varepsilon_1, \vec{a}; \Lambda, \vec{\tau} = 0) \quad \text{if } l \neq r,$$

(3.9)

$$\varepsilon_1\varepsilon_2 \log Z_l(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0) \text{ is regular at } \varepsilon_1 = \varepsilon_2 = 0.$$ (3.10)

(More precisely, only the proof of (3.9) was given in [8, (1.37)]. The proof of (3.10) was omitted since it is the same as [8, Theorem 4.4].)

**REMARK 3.11**

Although it was not stated explicitly in [20], the second assertion holds even if $l = r$. On the other hand, the first one follows from (3.8) for $d$ and $r + l - d$, which must be different. Therefore $l \neq r$ is required.

Let us apply the same argument to Proposition 2.13. We expand $Z_l^{\text{inst}}$ as before:

$$Z_l^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau}) = \sum \vec{n} \prod_{p \neq 0} \tau_p^{n_p} Z_{\vec{n}}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda)$$

with $\vec{n} = (\ldots, n_{-1}, n_1, \ldots)$. Thus

$$Z_{\vec{n}}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda) = \frac{1}{\vec{n}!} \left( \frac{\partial}{\partial \vec{\tau}} \right)^{\vec{n}} Z_l^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0).$$

By Proposition 2.13, we have

$$\left( \frac{\partial}{\partial \vec{t}} \right)^{\vec{n}} \hat{Z}_{l,0,d}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0, \vec{t} = 0) = 0$$

if $\vec{n}$ is nonzero and satisfies

$$- \sum_{p < 0} pn_p \leq d \leq r - \sum_{p > 0} pn_p.$$ (3.14)

After substituting (3.6) to the left-hand side, we also call this the blow-up equation.
For simplicity we assume that \( \vec{n} \) is supported on either \( \mathbb{Z}_{\geq 0} \) or \( \mathbb{Z}_{<0} \), that is, \( n_p = 0 \) for any \( p < 0 \) or \( n_p = 0 \) for any \( p > 0 \). We say that \( \vec{n} \) is positive in the first case and negative in the second case.

We define \( Z_{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau}) \) as follows. Since the perturbative part is already the exponential of something, we only need to define \( \log Z_{\text{inst}} \). Then observe that

\[
Z_{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau}) = \exp \left( \sum_{p, \alpha} \tau_p e^{pa_\alpha} \frac{(e^{\varepsilon_1/2} - e^{-\varepsilon_1/2})(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})}{(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})} \right) \times \left( 1 + O(\Lambda) \right).
\]

Therefore \( \log Z_{\text{inst}} \) can be defined as the sum of

\[
\sum_{p, \alpha} \tau_p e^{pa_\alpha} \frac{(e^{\varepsilon_1/2} - e^{-\varepsilon_1/2})(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})}{(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})}
\]

and a formal power series in \( \Lambda \).

**Proposition 3.15**

(1) Suppose that \( \vec{n} \) satisfies the following:

(a) If \( \sum n_p \) is odd, \(- (r + l)/2 \leq \sum_{p < 0} p n_p \) (negative case) or \( \sum_{p > 0} p n_p \leq (r - l)/2 \) (positive case).

(b) If \( \sum n_p \) is even, the strict inequality holds.

Then

\[
Z_{\vec{n}}(\varepsilon_1, -2\varepsilon_1, \vec{a}; \Lambda) = Z_{\vec{n}}(2\varepsilon_1, -\varepsilon_1, \vec{a}; \Lambda).
\]

(2) If \(- r < \sum_{p < 0} p n_p \) (negative case) or \( \sum_{p > 0} p n_p < r \) (positive case),

\[
\varepsilon_1 \varepsilon_2 \left( \frac{\partial}{\partial \vec{\tau}} \right) \vec{n} \log Z_l(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0)
\]

is regular at \( \varepsilon_1 = \varepsilon_2 = 0 \).

**Proof**

Since the proof of (2) is the same as that of (3.10), we only prove (1).

We expand \( Z_{\text{inst}}^l \) as

\[
Z_{\text{inst}}^l(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau}) = \sum_{N=0}^\infty Z_N(\varepsilon_1, \varepsilon_2, \vec{a}, \vec{\tau}) \Lambda^{2rN}.
\]

Note that

\[
Z_0(\varepsilon_1, \varepsilon_2, \vec{a}, \vec{\tau}) = \exp \left[ \sum_{p, \alpha} \tau_p e^{pa_\alpha} \frac{(e^{\varepsilon_1/2} - e^{-\varepsilon_1/2})(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})}{(e^{\varepsilon_2/2} - e^{-\varepsilon_2/2})} \right].
\]

Therefore the assertion is true for \( Z_0 \). We prove the assertion by induction on \( N \).

We further expand as

\[
Z_N(\varepsilon_1, \varepsilon_2, \vec{a}, \vec{\tau}) = \prod_{p \neq 0} \tau_p^{n_p} Z_{N, \vec{a}}(\varepsilon_1, \varepsilon_2, \vec{a})
\]

as in (3.12).
Fix \( \vec{n} \) and \( N \), and consider the coefficient of \( \Lambda^{2rN} \prod_{\vec{p}}^{n_{\vec{p}}} \) in (3.5). Setting \( \varepsilon_2 = -\varepsilon_1 \), we have

\[
0 = \sum_{(\vec{k}, \vec{\eta})/2 + N_1 + N_2 = N, \vec{n}_1 + \vec{n}_2 = \vec{n}} (-1)^{\sum_{n_{2,\vec{p}}}^{n_{2,p}}} e^{(d-1/2)(\vec{k}, \vec{\eta})e(N_1-\vec{n}_1)(d-(r+l)/2)e_1} \prod_{\vec{a} \in \Delta} l^k_{\vec{a}}(\varepsilon_1, -\varepsilon_1, \vec{a})
\]

(3.16) \quad \times \exp \left( \frac{1}{2} \sum_{\vec{a} \in \Delta} k^2_{\vec{a}} a_{\vec{a}} \right)

\[
\times Z_{N_1, \vec{n}_1}(\varepsilon_1, -2\varepsilon_1, \vec{a} + \varepsilon_1 \vec{k}) Z_{N_2, \vec{n}_2}(2\varepsilon_1, -\varepsilon_1, \vec{a} - \varepsilon_1 \vec{k})
\]

if \( \vec{n} \neq 0 \) by the blow-up equation (see (3.13), (3.5)). Here the summation is over \( \vec{k}, \vec{n}_1, \vec{n}_2, N_1, N_2 \), and we write \( \vec{n}_2 = (\ldots, n_{-2,1}, n_{2,1}, \ldots) \). We assume

\[
-\sum_{p<0} p n_p \leq d \leq r - \sum_{p>0} p n_p.
\]

We suppose that the same equality holds for \( r + l - d \). So we assume

\[
l + \sum_{p>0} p n_p \leq d \leq r + l + \sum_{p<0} p n_p.
\]

By our assumption, there exists \( d \) satisfying both inequalities; for example, we take \( d = r - \sum_{p>0} p n_p \) in the positive case, \( r + l + \sum_{p<0} p n_p \) in the negative case. Moreover, we may assume \( d \neq (r + l)/2 \) if \( \sum n_p \) is even.

Substituting \( r + l - d \) into \( d \) in (3.16) and replacing \( \vec{k} \) by \(-\vec{k}\), \( (N_1, N_2) \) by \( (N_2, N_1) \) and \( (\vec{n}_1, \vec{n}_2) \) by \( (\vec{n}_2, \vec{n}_1) \), we get

\[
0 = \sum_{(\vec{k}, \vec{\eta})/2 + N_1 + N_2 = N, \vec{n}_1 + \vec{n}_2 = \vec{n}} (-1)^{\sum_{n_{1,\vec{p}}}^{n_{1,p}}} e^{(d-1/2-r)(\vec{k}, \vec{\eta})e(N_1-\vec{n}_1)(d-(r+l)/2)e_1} \prod_{\vec{a} \in \Delta} l^k_{\vec{a}}(\varepsilon_1, -\varepsilon_1, \vec{a})
\]

\[
\times \exp \left( \frac{1}{2} \sum_{\vec{a} \in \Delta} k^2_{\vec{a}} a_{\vec{a}} \right) Z_{N_1, \vec{n}_1}(2\varepsilon_1, -\varepsilon_1, \vec{a} + \varepsilon_1 \vec{k}) Z_{N_2, \vec{n}_2}(\varepsilon_1, -2\varepsilon_1, \vec{a} - \varepsilon_1 \vec{k}).
\]

Note that

\[
\frac{e^{r(\vec{k}, \vec{\eta})/2}}{\prod_{\vec{a} \in \Delta} l^k_{\vec{a}}(\varepsilon_1, -\varepsilon_1, \vec{a})} = \frac{e^{-r(\vec{k}, \vec{\eta})/2}}{\prod_{\vec{a} \in \Delta} l^{-k}_{\vec{a}}(\varepsilon_1, -\varepsilon_1, \vec{a})}
\]

by [20, Lemma 4.1, (4.2)]. Note also that \( \sum n_{1,p} = \sum n_p - \sum n_{2,\vec{p}} \) and hence we can replace \( (-1)^{\sum_{n_{1,\vec{p}}}^{n_{1,p}}} \) by \( (-1)^{\sum_{n_{2,\vec{p}}}^{n_{2,p}}} \) in the above formula. Then the only difference between the above two equations is variables for \( Z_{N_1, \vec{n}_1} \) and \( Z_{N_2, \vec{n}_2} \). By the induction hypothesis, those are also equal if \( N_1, N_2 < N \). Therefore we have

\[
0 = \sum_{\vec{n}_1 + \vec{n}_2 = \vec{n}} (-1)^{\sum_{n_{2,\vec{p}}}^{n_{2,p}}} e^{N(d-(r+l)/2)e_1} Z_{N_1, \vec{n}_1}(\varepsilon_1, -2\varepsilon_1, \vec{a}) Z_{0, \vec{n}_2}(2\varepsilon_1, -\varepsilon_1, \vec{a})
\]

\[
+ e^{-N(d-(r+l)/2)e_1} Z_{0, \vec{n}_1}(\varepsilon_1, -2\varepsilon_1, \vec{a}) Z_{N_2, \vec{n}_2}(2\varepsilon_1, -\varepsilon_1, \vec{a})
\]

\[
- e^{N(d-(r+l)/2)e_1} Z_{N, \vec{n}_1}(2\varepsilon_1, -\varepsilon_1, \vec{a}) Z_{0, \vec{n}_2}(\varepsilon_1, -2\varepsilon_1, \vec{a})
\]

\[
- e^{-N(d-(r+l)/2)e_1} Z_{0, \vec{n}_1}(2\varepsilon_1, -\varepsilon_1, \vec{a}) Z_{N, \vec{n}_2}(\varepsilon_1, -2\varepsilon_1, \vec{a})
\]

(3.17)
\[ = \sum_{\vec{n}_1 + \vec{n}_2 = \vec{n}} (-1)^{\sum n_p} \left[ e^{N(d-(r+l)/2)\varepsilon_1} Z_{0,\vec{n}_2}(2\varepsilon_1, -\varepsilon_1, \vec{a}) \right. \]

\[ \times \{ Z_{N,\vec{n}_1}(\varepsilon_1, -2\varepsilon_1, \vec{a}) - Z_{N,\vec{n}_1}(2\varepsilon_1, -\varepsilon_1, \vec{a}) \} \]

\[ + e^{-N(d-(r+l)/2)\varepsilon_1} Z_{0,\vec{n}_1}(\varepsilon_1, -2\varepsilon_1, \vec{a}) \]

\[ \times \{ Z_{N,\vec{n}_2}(2\varepsilon_1, -\varepsilon_1, \vec{a}) - Z_{N,\vec{n}_2}(\varepsilon_1, -2\varepsilon_1, \vec{a}) \}, \]

if \( \vec{n} \neq 0 \).

We now prove the assertion by induction on \( \vec{n} \). The case \( \vec{n} = 0 \) is treated already in (3.9).

Now we assume that the assertion holds for smaller \( \vec{n} \). Note that the assumption on \( \vec{n} \) implies that on smaller ones. Then the only remaining terms in (3.17) are either \( \vec{n}_1 = 0 \) or \( \vec{n}_2 = 0 \). Therefore we have

\[ 0 = \left( e^{N(d-(r+l)/2)\varepsilon_1} - (-1)^{\sum n_p} e^{-N(d-(r+l)/2)\varepsilon_1} \right) \]

\[ \times \{ Z_{N,\vec{n}}(\varepsilon_1, -2\varepsilon_1, \vec{a}) - Z_{N,\vec{n}}(2\varepsilon_1, -\varepsilon_1, \vec{a}) \}. \]

Hence we have the assertion for \( Z_{N,\vec{n}} \). Note that we take \( d \neq (r + l)/2 \) when \( \sum n_p \) is even, so the above is a nontrivial equality. \( \square \)

**REMARK 3.18**
We need the vanishing (3.16) for the case when \( \sum n_p \) is odd, but it is enough to suppose that the right-hand side of (3.16) is the same for \( d \) and \( r + l - d \) when \( \sum n_p \) is even. In particular, if we use (3.8) instead of (3.13), the above argument works even for \( \vec{n} = 0 \). This is nothing but the proof of (3.9) in [8].

### 3.3. Contact term equations

We expand as

\[ \varepsilon_1 \varepsilon_2 \log Z_i(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau}) \]

\[ = F_0(\vec{a}; \Lambda, \vec{\tau}) + (\varepsilon_1 + \varepsilon_2) H(\vec{a}; \Lambda, \vec{\tau}) + \varepsilon_1 \varepsilon_2 A(\vec{a}; \Lambda, \vec{\tau}) + \varepsilon_1^2 + \varepsilon_2^2 \frac{B(\vec{a}; \Lambda, \vec{\tau}) + \cdots}{3}, \]

where we consider only \( (\partial/\partial \vec{\tau})^\vec{n} |_{\vec{\tau}=0} \) applied to this function, with \( \vec{\tau} \) in the range in Proposition 3.15(2) so that singular terms do not appear.

By (3.9), \( H(\vec{a}; \Lambda, \vec{\tau} = 0) \) comes only from the perturbative part. Thus we have \( H(\vec{a}; \Lambda, \vec{\tau} = 0) = -\pi \sqrt{-1} \langle \vec{a}, \rho \rangle \), where \( \rho \) is the half-sum of the positive roots. More generally, by Proposition 3.15(1) we have

\[ \left( \frac{\partial}{\partial \vec{\tau}} \right)^\vec{n} H(\vec{a}; \Lambda, \vec{\tau} = 0) = 0 \]

if \( \vec{n} \) satisfies the condition there.

We introduce a new coordinate system for \( \vec{a} \) by \( a^i = a_1 + a_2 + \cdots + a_i (i = 1, \ldots, r - 1) \) as in [19, Section 1]. We also define \( k^i \) for \( \vec{k} \) in the same way.

Let

\[ \tau_{ij} = -\frac{1}{2\pi \sqrt{-1}} \frac{\partial^2 F_0(\vec{a}; \Lambda, \vec{\tau} = 0)}{\partial a^i \partial a^j}. \]
Let \( \Theta_E(\xi | \tau) \) be the Riemann theta function defined by
\[
\Theta_E(\xi | \tau) = \sum_{\ell \in \mathbb{Z}^r \cdot 1} \exp \left( \pi \sqrt{-1} \sum_{i,j} \tau_{ij} k^i j^j + 2\pi \sqrt{-1} \sum_i k^i \left( \xi^i + \frac{1}{2} \right) \right).
\]

We substitute (3.6) into the left-hand side of (3.8) and take the limit of \( \varepsilon_1, \varepsilon_2 \to 0 \). Using \( H(\bar{a}; \Lambda, \bar{\tau} = 0) = -\pi \sqrt{-1} \langle \bar{a}, \rho \rangle \), we obtain
\[
\exp(B - A) = \exp \left[ -\frac{1}{8r^2} \left( d - \frac{r + l}{2} \right)^2 \frac{\partial^2 F_0}{(\partial \log \Lambda)^2} \right] \times \Theta_E \left( -\frac{1}{2\pi \sqrt{-1}} 2r \left( d - \frac{r + l}{2} \right) \frac{\partial^2 F_0}{\partial \log \Lambda \partial \bar{a}} \bigg| \tau \right)
\]
for \( 0 \leq d \leq r \) as in [20, Section 4]. Here \( F_0, A, B \) are evaluated at \( (\bar{a}; \Lambda, \bar{\tau} = 0) \).

In particular, the right-hand side is independent of \( d \). Dividing by the expression for \( d = (r + l)/2 \) (if \( r + l \) is even) or \( d = (r + l - 1)/2 \) (if \( r + l \) is odd), we have
\[
\frac{\Theta_E(-1/(4\pi \sqrt{-1}r))(d - (r + l)/2)(\partial^2 F_0)/(\partial \log \Lambda \partial \bar{a}) | \tau)}{\Theta_E(0 | \tau)} = \exp \left[ \frac{1}{8r^2} \left( d - \frac{r + l}{2} \right)^2 \frac{\partial^2 F_0}{(\partial \log \Lambda)^2} \right],
\]
(3.20)
\[
\frac{\Theta_E(-1/(4\pi \sqrt{-1}r))(d - (r + l)/2)(\partial^2 F_0)/(\partial \log \Lambda \partial \bar{a}) | \tau)}{\Theta_E(1/(8\pi \sqrt{-1}r)(\partial^2 F_0)/(\partial \log \Lambda \partial \bar{a}) | \tau)} = \exp \left[ \frac{1}{8r^2} \left( d - \frac{r + l}{2} \right)^2 - \frac{1}{4} \right] \frac{\partial^2 F_0}{(\partial \log \Lambda)^2}
\]
according to whether \( r + l \) is even or odd. This equation is called the contact term equation. This equation determines \( F_0(\bar{a}; \Lambda, \bar{\tau} = 0) \) recursively in the expansion with respect to \( \Lambda \), starting from the perturbation part.

Here we recall again that our full partition function, and hence \( \tau_{ij} \) and \( \Theta_E(\xi | \tau) \), and so on do not have the rigorous meaning (see Remark 3.7). The rigorous form of the contact term equation is given by rewriting it as an equation for the instanton part. This was given in [19, (7.5)] for the homological version of Nekrasov partition function, but we do not give it here since it is not enlightening.

Similarly to the limit of (3.13), we obtain
\[
0 = -\frac{1}{2r} \left( d - \frac{r + l}{2} \right) \frac{\partial}{\partial \log \Lambda} \left( \frac{\partial}{\partial \bar{\tau}} \right) \tilde{n} F_0(\bar{a}; \Lambda, \bar{\tau} = 0)
\]
(3.21)
\[
-\frac{1}{2\pi \sqrt{-1}} \sum_i \frac{\partial \log \Theta_E}{\partial \xi^i} |_{\xi = -1/(4\pi \sqrt{-1}r)(d - (r + l)/2)(\partial^2 F_0)/(\partial \log \Lambda \partial \bar{a})} \times \frac{\partial}{\partial a^i} \left( \frac{\partial}{\partial \bar{\tau}} \right) \tilde{n} F_0(\bar{a}; \Lambda, \bar{\tau} = 0)
\]
when \( \tilde{n} \) is nonzero, either positive or negative, and satisfies (3.14) and (3.15)(1.a), (1.b). We call this the contact term equation for \( (\partial/\partial \bar{\tau})\tilde{n} F_0 \). This derivation of
the contact term equation from the blow-up equation can be done in the same way as in [18, Section 5.3].

Since \( \partial \log \Theta_E / \partial \xi^i \) is divisible by \( \Lambda \), this equation determines \( (\partial / \partial \bar{\tau}) \bar{n} F_0 \) recursively in the expansion with respect to \( \Lambda \) starting from the constant term

\[
\frac{\partial}{\partial \bar{\tau}} \sum_{p, \alpha} e^{\bar{p} \alpha} |_{\Lambda = 0}
\]

(3.22)

\[
= \begin{cases} 
\sum_{\alpha} e^{\bar{p} \alpha} |_{\Lambda = 0} & \text{if } n_p = 1 \text{ and } n_q = 0 \text{ for } q \neq p, \\
0 & \text{otherwise}.
\end{cases}
\]

In particular, we have

\[
\frac{\partial}{\partial \bar{\tau}} \sum_{p, \alpha} e^{\bar{p} \alpha} |_{\Lambda = 0, \bar{\tau} = 0} = 0
\]

unless \( n_p = 1 \) and \( n_q = 0 \) for \( q \neq p \). The remaining \( \partial F_0 / \partial \tau_p \) is determined in Section 3.4.

Since higher derivatives vanish, we have

\[
\frac{\partial}{\partial \bar{\tau}} \sum_{p, \alpha} e^{\bar{p} \alpha} |_{\Lambda = 0, \bar{\tau} = 0} = 0
\]

By (3.2), this is equal to

\[
\left. \left( \frac{\partial}{\partial \bar{\tau}} \right)^n F_0 (\bar{a}; \Lambda, \bar{\tau} = 0) \right|_{\bar{\tau} = 0} = 0
\]

unless \( n_p = 1 \) and \( n_q = 0 \) for \( q \neq p \). The remaining \( \partial F_0 / \partial \tau_p \) is determined in Section 3.4.

3.4. Seiberg-Witten prepotential

We give a quick review of the Seiberg-Witten prepotential for the theory with 5-dimensional Chern-Simons term in this subsection (see [8, Appendix A] for more detail). (We change the notation slightly: \( m \) in [8] is our \( l \) and \( a_i \) is our \( a_\alpha \). \( \beta \) is set to be 1.)

We consider a family of hyperelliptic curves parameterized by \( \bar{U} = (U_1, \ldots, U_{r-1}) \):

\[
C_{\bar{U}, l} : Y^2 = P(X)^2 - 4(-X)^{r+l} \Lambda^{2r}
\]

\[
P(X) = X^r + U_1 X^{r-1} + U_2 X^{r-2} + \cdots + U_{r-1} X + (-1)^r
\]
for $-r < l < r$, $l \in \mathbb{Z}$. Note that we set $\beta = 1$ from [8] for brevity. We call them Seiberg-Witten curves. We define the Seiberg-Witten differential by

$$dS = \frac{1}{2\pi \sqrt{-1}} \log X \frac{2XP'(X) - (r + l)P(X)}{2XY} \, dX.$$ 

We choose $z_\alpha$ ($\alpha = 1, \ldots, r$) so that $X_\alpha = e^{-\sqrt{-1}z_\alpha}$ are zeros of $P(X) = 0$. Then we take the cycles $A_\alpha, B_\alpha$ ($\alpha = 2, \ldots, r$) in a way explained in [8].

We define $a_\alpha, a^D_\alpha$ by

$$a_\alpha = \int_{A_\alpha} dS, \quad a^D_\alpha = \int_{B_\alpha} dS.$$ 

We then invert the role of $a_\alpha$ and $U_p$, so we consider $a_\alpha$ as variables and $U_p$ as functions in $a_\alpha$. Here we use $a_\alpha = -\sqrt{-1}z_\alpha + O(\Lambda)$ [8, (A.1)].

Then one can show that there exists a locally defined function $F_0 = F_0(\vec{a}; \Lambda)$ such that

$$a^D_\alpha = -\frac{1}{2\pi \sqrt{-1}} \frac{\partial F_0}{\partial a_\alpha}.$$ 

This defines $F_0$ up to a function (in $\Lambda$) independent of $\vec{a}$. This ambiguity is fixed by specifying $\partial F_0 / \partial \log \Lambda$ and the perturbation part of $F_0$ (see [8] for details).

It was proved in [8, (A.27), (A.33)] that $F_0$ satisfies the contact term equations (3.20), where the period matrix ($\tau$) is defined by the same formula as (3.19) by replacing $F_0$ by $F_0$. Moreover, it was also proved that $F_0$ has the same perturbation part as $F_0$ [8, Proposition A.6]. Therefore the recursive structure of (3.20) implies that $F_0 = F_0$; that is, the leading part of the Nekrasov partition function is equal to the Seiberg-Witten prepotential.

In [8, (A.25)], it was proved that

$$J = \frac{1}{2r} \frac{\partial U_p}{\partial \log \Lambda} + \frac{1}{2\pi \sqrt{-1}} \sum_i \left| \frac{\partial \log \Theta_E}{\partial \xi^i} \bigg|_{\vec{\xi} = -1/(4\pi \sqrt{-1})r(\partial^2 F_0)/(\partial \log \Lambda \partial \vec{a})} \right| \frac{\partial U_p}{\partial a^i}$$

under the assumption that $r + l$ is even. This is the same as (3.21) with $d = -(r + l)/2 = \pm 1$. When $r + l$ is odd, we assume that $U_p$ satisfies (3.21) with $d = (r + l + 1)/2$ for a moment and gives a proof later.

The initial condition for $U_p$ is

$$U_p = (-1)^p e_p(X_1, \ldots, X_r) = (-1)^p e_p(e^{a_1}, \ldots, e^{a_r})$$

at $\Lambda = 0$, where $e_p$ is the $p$th elementary symmetric polynomial. Noticing that (3.21) holds for polynomials in $\partial F_0 / \partial \tau_p$, we see that $(-1)^p U_p$ and $\partial F_0 / \partial \tau_p$ are related in exactly the same way as an elementary symmetric polynomial and a power sum by (3.22).

**Theorem 3.25**

An equation

$$\frac{\partial F_0}{\partial \tau_p}(\vec{a}; \Lambda, \vec{r} = 0) = X_1^p + \cdots + X_r^p$$

holds for $-(r + l)/2 \leq p \leq (r - l)/2$. 
Note that all $U_p$'s are written by polynomials in $\frac{\partial E_2}{\partial \tau_2}(\vec{a}; \Lambda, \vec{\tau} = 0)$ in the above range, as $X_1 \cdots X_r = 1$. Thanks to (3.23), the polynomials can be replaced by those in Adams operators. We thus have

$$U_p = \frac{(-1)^p}{\mathcal{Z}_{\text{inst}}^{\text{inst}}(\varepsilon_1, \varepsilon_2, \vec{a}; \Lambda, \vec{\tau} = 0)} \sum_c (\Lambda^{2r} e^{-(r+l)(\varepsilon_1+\varepsilon_2)/2}(\Delta(c),[F]))$$

$$\times \int_{M(c)} \text{ch}(\wedge^p (\mathcal{E}/[0])) \text{td}(c, \mathcal{V}(\mathcal{E})) \bigg|_{\varepsilon_1 = \varepsilon_2 = 0}$$

for $0 < p \leq (r - l)/2$. For $(r - l)/2 \leq p < r$, the equation holds if we replace $\wedge^p (\mathcal{E}/[0])$ by $\wedge^{r-p} (\mathcal{E}/[0])^r$. This equation gives a moduli-theoretic description of the coefficients $U_p$ in the Seiberg-Witten curves.

It remains to show that $U_p$ satisfies (3.21) with $d = (r + l + 1)/2$ in the case when $r + l$ is odd. Let us give a sketch of the argument. We use the notation in [8]; for example, $E(X_1, X_2)$ is the prime form, $\omega_{\infty+,-0}$ is the meromorphic differential with the vanishing $A$-periods having poles $0_-$ and $\infty_+$ of residue $-1$, $+1$, respectively, and so on.

By [8, Corollary 2.11], we have

$$\frac{\Theta^2_2((1/2) \int_{0_-+\infty_+} \omega)}{\Theta^2_2((1/2) \int_{0_-+\infty_+} \omega)} \frac{E(0_-, \infty_+)}{E(X, 0_-)E(X, \infty_+)} = \omega_{\infty_+,-0_+}(X) + 2 \times \frac{1}{2\pi \sqrt{-1}} \sum_i \frac{\partial \log \Theta E}{\partial \xi^i} \bigg|_{\xi = (1/2) \int_{0_-+\infty_+} \omega} \omega_i(X).$$

By [4, (A.18)], we have

$$\frac{(P(X) - Y)dX}{2XY} - \frac{1}{2r} \sum_{p=1}^{r-1} \frac{\partial U_p}{\partial \log A} \frac{X^{r-p-1}dX}{Y} = \omega_{\infty_+,-0_-}(X).$$

Therefore it is enough to show

$$\frac{(P(X) - Y)dX}{2XY} = \frac{\Theta^2_2((1/2) \int_{0_-+\infty_+} \omega)}{\Theta^2_2((1/2) \int_{0_-+\infty_+} \omega)} \frac{E(0_-, \infty_+)}{E(X, 0_-)E(X, \infty_+)}.$$

As in [8, Section A.7] we take the branched double cover $p: \hat{C}_{\mathcal{U}^2} \rightarrow C_{\mathcal{U}^2}$ given by $W \mapsto X = W^2$. It is given by

$$Y^2 = P(W^2)^2 - 4(-W^2)^{r+l}A^{2r}$$

$$= (P(W^2) - 2(\sqrt{-1}W)^{r+l}A^r)(P(W^2) + 2(\sqrt{-1}W)^{r+l}A^r).$$

We consider the Szegő kernel for $\hat{C}_{\mathcal{U}^2}$ given by

$$\Psi_E(W_1, W_2) = \frac{\hat{\Theta}_E(f_{W_1, W_2} \omega)}{\hat{\Theta}_E(0)E(W_1, W_2)},$$
where $\hat{\Theta}_E$ is the Riemann theta function for the curve $\hat{C}_{\vec{U}, l}$. As in [8, Section A.6, first two displays] we have

$$\Psi_E(W, \infty_+)^2 = -\frac{Y - P(W^2)}{2Y} dW \left(\frac{1}{W_2}\right)_{W_2 = \infty_+}.$$  

From the defining equation (3.27) of the double cover, this has zero of order $2(r + l)$ at $0_+$ and of order $2(r - l - 1)$ at $\infty_-$. Therefore

$$\text{div} \hat{\Theta}_E(W - \infty_+) = (r + l) \cdot 0_+ + (r - l - 1) \cdot \infty_-$$

(see [8, pp. 16, 17] for basic properties of $E(W_1, W_2)$).

If we identify the half-integer characteristic $\hat{E}$ with a vector in $\mathbb{C}^{2r-1}$ so that $\hat{\Theta}_E(\xi) = \hat{\Theta}(\xi - \hat{E})$, we have

$$\hat{E} = (r + l) \cdot 0_+ + (r - l - 1) \cdot \infty_- - \infty_+ - \hat{\Delta},$$

where $\hat{\Delta}$ is the Riemann divisor class (4, Theorem 1.1)

By [8, Lemma A.32], we have

$$\hat{E} = p^* E - [0, c_*, 0],$$

where $p^*: J_0(C_{\vec{U}, l}) \to J_0(\hat{C}_{\vec{U}, l})$.

On the other hand, we have

$$\hat{\Delta} - p^* \Delta = 0_- + \infty_- + p^* \left(\frac{1}{2} \int_{0_-}^{\infty_+} \vec{\omega}\right) + [0, c_*, 0]$$

by [4, Proposition 5.3].

From (3.28)–(3.30) we get

$$E = \frac{r + l - 1}{2} \cdot 0_+ + \frac{r - l - 1}{2} \cdot \infty_- - \frac{1}{2} \int_{0_-}^{\infty_+} \vec{\omega} - \Delta,$$

where we have used $0_+ - \infty_- = \infty_+ - 0_-$. Therefore $\Theta_E(\{(1/2)^{2X}_{0_- + \infty_+} \vec{\omega}\})$ has zero of order $(r + l - 1)/2$ at $0_+$ and of order $(r - l - 1)/2$ at $\infty_-$, again by [4, Theorem 1.1].

On the other hand, the left-hand side of (3.26) has zero of order $r + l - 1$ at $0_+$ and of order $r - l - 1$ at $\infty_-$. Both sides of (3.26) have poles at $0_-, \infty_+$ with residues $-1, 1$, respectively (see [4, Corollary 2.11]). Therefore we have (3.26).

Although it is not necessary, let us also sketch how to prove (3.21) for more general $d$.

We first assume that $r + l$ is even and generalize (3.24) as

$$0 = \frac{d}{2r} \frac{\partial U_p}{\partial \log \Lambda} + \frac{1}{2\pi \sqrt{-1}}$$

$$\times \sum_i \frac{\partial \log \Theta_E}{\partial \xi^i} \bigg|_{\xi = -(d/4\pi \sqrt{-1} \text{Tr}) \left(\partial^2 F_0 / (\partial \log \Lambda \partial \bar{a}) \right)} \frac{\partial U_p}{\partial a^i}$$

for $|d| \leq (r - l)/2$. This equation is nothing but (3.21) with $d - (r + l)/2$ replaced by $d$. In terms of the $d$ in (3.21), the condition is $l \leq d \leq r$. This is exactly the one under which we have proved (3.21) for all $p$ from the vanishing theorem.
To show (3.31) we use [8, Section A.6.2, first displayed formula], which is [4, Corollary 2.19 (43)]. We replace $d$ with $d + 1$ and take 
$x_0 = X$, $y_0 = X'$, 
$x_1 = \ldots = x_d = 0$, $y_1 = \ldots = y_d = \infty_+$. We then get
\[
\frac{\Theta_E \left( \int_{d^{\infty_+} X'} \omega \right)}{\Theta_E (0) E(X, X')} \times \left( \frac{E(X, 0_-) E(\infty_+, X')}{E(X, \infty_+) E(0_-, X')} \right)^d \left( E(0_-, \infty_+) \sqrt{dX_1} \right) \frac{\sqrt{dX_2}}{X_2} \right)_{X_2 = \infty}^{-d^2} = \Psi E(X, X') - \frac{\Psi E(0_-, X') \Psi E(X, \infty_+)}{\Psi E(0_-, \infty_+)} 1 - \frac{(X/X')^d}{1 - (X/X')}.
\]
This is proved exactly as in [8, Section A.6.2], so the detail is omitted. We multiply both sides $E(X, X')$, differentiate with respect to $X'$, and set $X' = X$. We get
\[
\sum_{\alpha = 2}^r \frac{\partial \log \Theta_E}{\partial \xi_\alpha} \left( 2d \int_{0_-}^{\infty_+} \omega (X) + d \times \omega_{\infty_+ - 0_-} (X) \right) \tag{3.32}
\]
\[= d \frac{\Psi E(X, 0_-) \Psi E(X, \infty_+)}{\Psi E(0_-, \infty_+)} \]
as in [15, IIIb Section 3, p. 226]. When $d = 1$, this is nothing but [8, (A.24)]. From the argument in [8, Section A.6.1], we get (3.31).

We next consider the case when $r + l$ is odd. We take the branched double cover $p: \tilde{C}_{\mathcal{U}, l} \rightarrow C_{\mathcal{U}, l}$ given by $W \mapsto X = W^2$ as before. Then $r$, $l$ become $2r$, $2l$ for $\tilde{C}_{\mathcal{U}, l}$, and hence we have (3.32) for $\tilde{C}_{\mathcal{U}, l}$ with $d$ replaced by $2d$:
\[
\sum_{\alpha = 2}^r \frac{\partial \log \tilde{\Theta}_E}{\partial \xi_\alpha} \left( 2d \int_{0_-}^{\infty_+} \tilde{\omega} (W) \right) 
+ \sum_{\alpha = 2}^r \frac{\partial \log \tilde{\Theta}_E}{\partial \xi_\alpha} \left( 2d \int_{0_-}^{\infty_+} \tilde{\omega}' (W) \right) 
+ \frac{\partial \log \tilde{\Theta}_E}{\partial \xi_\alpha} \left( 2d \int_{0_-}^{\infty_+} \tilde{\omega} (W) \right) + 2d \times \tilde{\omega}_{\infty_+ - 0_-} (W) 
= 2d \frac{\tilde{\Psi}_E(W, 0_-) \tilde{\Psi}_E(W, \infty_+)}{\tilde{\Psi}_E(0_-, \infty_+)} ,
\]
where we take cycles $A_\alpha$, $B_\alpha$, $A_\ast$, $B_\ast$, $A'_\alpha$, $B'_\alpha$ as in [8, Section A.7] and the corresponding coordinates $\tilde{\xi}_\alpha$, $\tilde{\xi}_\ast$, $\tilde{\xi}'_\alpha$ on $J_0(\tilde{C}_{\mathcal{U}, l})$. This holds if $|d| \leq (r - l)/2$ as above. The right-hand side is
\[
2d \frac{(P(W^2) - Y)dW}{2YW} = dp^* \left( \frac{(P(X) - Y)dX}{2XY} \right)
\]
as [8, Section A.6.1, second displayed equation]. We also have
\[
\tilde{\omega}_{\infty_+ - 0_-} (W) = \frac{1}{2} p^* \omega_{\infty_+ - 0_-} (X)
\]
by definition.

On the other hand, we rewrite the theta function \( \hat{\Theta}_{\hat{E}} \) by \( \Theta_{E} \) by using [8, (A.29)] and the second displayed formula in p. 1105. We then get

\[
\frac{1}{2} \sum_{\alpha=2}^{r} \left\{ \frac{\partial \log \Theta_{E}}{\partial \xi_{\alpha}} \left( \left( d + \frac{1}{2} \right) \int_{0_{-}}^{\infty_{+}} \omega \right) + \frac{\partial \log \Theta_{E}}{\partial \xi_{\alpha}} \left( \left( d - \frac{1}{2} \right) \int_{0_{-}}^{\infty_{+}} \omega \right) \right\} \omega_{\alpha}(X)
+ d \times \omega_{\infty_{+}-0_{-}}(X) = d \left( P(X) - Y \right) dX.
\]

From this we get

\[
0 = \frac{d}{2r} \frac{\partial \log \Lambda}{\partial \log \Lambda}
+ \frac{1}{2} \sum_{\alpha=2}^{r} \left\{ \frac{\partial \log \Theta_{E}}{\partial \xi_{\alpha}} \left| \xi_{\alpha} = -(d+1/2)/(4\pi \sqrt{-1}) \right. \right\} \frac{\partial U_{\alpha}}{\partial \alpha_{\alpha}}
+ \frac{1}{2} \sum_{\alpha=2}^{r} \left\{ \frac{\partial \log \Theta_{E}}{\partial \xi_{\alpha}} \left| \xi_{\alpha} = -(d-1/2)/(4\pi \sqrt{-1}) \right. \right\} \frac{\partial U_{\alpha}}{\partial \alpha_{\alpha}}
\]

as in [8, Section A.6.1]. This is nothing but the sum of (3.21) for \( d \) replaced by \( d + (r + l + 1)/2 \) and \( d + (r + l - 1)/2 \). Since we have already proved (3.21) for \( (r + l - 1)/2 \), we have (3.21) for \( l \leq d \leq r \).

4. Quiver description

In this section we review the result of [22], rephrase that of [21] in the quiver description, and add a few things on Ext-groups.

4.1. Moduli spaces of \( m \)-stable sheaves

We take vector spaces \( V_{0}, V_{1}, W \) with

\[
r = \dim W, \quad (c_{1}, [C]) = \dim V_{0} - \dim V_{1}, \quad (ch_{2}, [\hat{P}^{2}]) = -\frac{1}{2} (\dim V_{0} + \dim V_{1}).
\]

We consider following datum \( X = (B_{1}, B_{2}, d, i, j) \):

- \( B_{1}, B_{2} \in \text{Hom}(V_{1}, V_{0}), d \in \text{Hom}(V_{0}, V_{1}), i \in \text{Hom}(W, V_{0}), j \in \text{Hom}(V_{1}, W), \)

\[
\xymatrix{
V_{0} \ar[r]^{B_{1}, B_{2}} \ar[d]_{i} & V_{1} \ar[d]_{j} \ar[l]^{d} \ar[u]_{B_{1}, B_{2}} \\
W & \ }
\]

- \( \mu(B_{1}, B_{2}, d, i, j) = B_{1}dB_{2} - B_{2}dB_{1} + ij = 0. \)

Let \( Q := \mu^{-1}(0) \) be the subscheme of the vector space \( \text{Hom}(V_{1}, V_{0}) \oplus \text{Hom}(V_{0}, V_{1}) \oplus \text{Hom}(W, V_{0}) \oplus \text{Hom}(V_{1}, W) \) defined by the equation \( \mu = 0 \). It is acted on by \( G := \text{GL}(V_{0}) \times \text{GL}(V_{1}) \):

\[
g \cdot \left( B_{1}, B_{2}, d, i, j \right) = \left( g_{0}B_{1}g_{1}^{-1}, g_{0}B_{2}g_{2}^{-1}, g_{1}dg_{0}^{-1}, g_{0}i, g_{1}j^{-1} \right).
\]
Let \( \zeta = (\zeta_0, \zeta_1) \in \mathbb{Q}^2 \).

**Definition 4.1**

We say that \( X = (B_1, B_2, d, i, j) \) is \( \zeta \)-semistable if

1. for subspaces \( S_0 \subset V_0, S_1 \subset V_1 \) such that \( B_0(S_1) \subset S_0 \) (\( \alpha = 1, 2 \)), \( d(S_0) \subset S_1, \ker j \supset S_1 \), we have \( \zeta_0 \dim S_0 + \zeta_1 \dim S_1 \leq 0 \);
2. for subspaces \( T_0 \subset V_0, T_1 \subset V_1 \) such that \( B_0(T_1) \subset T_0 \) (\( \alpha = 1, 2 \)), \( d(T_0) \subset T_1 \), \( \text{Im} \ i \subset T_0 \), we have \( \zeta_0 \dim T_0 + \zeta_1 \dim T_1 \geq 0 \).

We say that \( X \) is \( \zeta \)-stable if the inequalities are strict unless \( (S_0, S_1) = (0, 0) \) and \( (T_0, T_1) = (V_0, V_1) \), respectively.

We say that \( X_1, X_2 \) are \( S \)-equivalent when the closures of orbits intersect in the \( \zeta \)-semistable locus of \( Q \).

By a standard argument, we can see that these come from quotients of \( Q \) by \( G \) in the geometric invariant theory. We explain only the result (see [10] for details).

Let \( \chi : G \to \mathbb{C}^* \) be the character given by \( \chi(g) = \det g_0^{-\zeta_0} \det g_1^{-\zeta_1} \), where we assume \( (\zeta_0, \zeta_1) \in \mathbb{Z}^2 \) by multiplying by a positive integer if necessary. We have a lift of \( G \)-action on the trivial line bundle \( Q \times \mathbb{C} \) given by

\[
(B_1, B_2, d, i, j, z) = (g \cdot (B_1, B_2, d, i, j), \chi(g)z).
\]

Let \( L_\zeta \) denote the corresponding \( G \)-equivariant line bundle. Then we can consider the GIT quotient

\[
\widehat{M}_\zeta = \text{Proj} \left( \bigoplus_{n \geq 0} A(Q)^{\chi \cdot n} \right),
\]

where \( A(Q)^{\chi \cdot n} \) is the relative invariants in the coordinate ring \( A(Q) \) of \( Q \): \( \{ f \in A(Q) \mid f(g \cdot X) = \chi(g)^n f(X) \} \), which is the space of invariant sections of \( L_\zeta^{\otimes n} \).

Then \( \widehat{M}_\zeta \) is the quotient of the \( \zeta \)-semistable locus modulo the \( S \)-equivalence relation. It contains \( \widehat{M}_\zeta^s \) of the quotient of the \( \zeta \)-stable locus modulo the action of \( G \).

We have a natural projective morphism \( \tilde{\pi} : \widehat{M}_\zeta \to \mu^{-1}(0)/\!/G \), where \( \mu^{-1}(0)/\!/G \) is the affine GIT quotient of \( \mu^{-1}(0) \) by \( G \), that is, \( \widehat{M}_0 \). By [22, Section 1.3], \( \mu^{-1}(0)/\!/G \) is isomorphic to \( M_0 \), the Uhlenbeck partial compactification on \( \mathbb{P}^2 \).

Now the main result of [22] says the following.

**Theorem 4.2**

Let \( m \in \mathbb{Z}_{\geq 0} \). Suppose that \( \zeta_0 < 0, 0 > m\zeta_0 + (m + 1)\zeta_1 \gg -1 \). Then we have \( \widehat{M}_\zeta = \widehat{M}_\zeta^s \), and it is bijective to the set of isomorphism classes of \( m \)-stable framed sheaves on \( \mathbb{P}^2 \).

We use this result as the definition of the moduli scheme of \( m \)-stable framed sheaves in this paper. Therefore \( \widehat{M}_\zeta \) is denoted by \( \widehat{M}^m \) (or \( \widehat{M}^m(c) \) when we...
want to write the Chern character of sheaves) hereafter. It was proved in [22, Lemma 2.4] that

(a) $d\mu$ is surjective and
(b) the action of $G$ is free on the $\zeta$-stable locus.

Therefore $\hat{M}_\zeta$ is a smooth fine moduli scheme.

The construction is given as follows. We consider the complex

$$
\begin{align*}
V_0 \otimes O(C - \ell_\infty) & \oplus \mathbb{C}^2 \otimes \mathbb{C} \oplus V_1 \otimes O(\ell_\infty) \\
V_1 \otimes O(-\ell_\infty) & \oplus \mathbb{C}^2 \otimes V_1 \otimes O(-C + \ell_\infty) \\
W & \otimes O
\end{align*}
$$

with

$$
\alpha = \begin{bmatrix}
z & z_0B_1 \\
w & z_0B_2 \\
z_1 - z_0dB_1 & 0 \\
z_2 - z_0dB_2 & 0 \\
0 & z_0j
\end{bmatrix}, \quad \beta = \begin{bmatrix}
z_2 & -z_1 & B_2z_0 & -B_1z_0 & iz_0 \\
dw & -dz & w & -z & 0
\end{bmatrix}.
$$

The equation $\mu(B_1, B_2, d, i, j) = B_1dB_2 - B_2dB_1 + ij = 0$ is equivalent to $\beta\alpha = 0$. The stability condition ensures the injectivity of $\alpha$ and the surjectivity of $\beta$. Then the sheaf corresponding to $(B_1, B_2, d, i, j)$ is defined by $E = \text{Ker} \beta / \text{Im} \alpha$. By the definition, it is endowed with the framing $E|_{\ell_\infty} \to W \otimes O_{\ell_\infty}$. The $\zeta$-stability is identified with the $m$-stability.

The inverse construction is given by

$$
V_0 := H^1(E(-\ell_\infty)), \quad V_1 := H^1(E(C - \ell_\infty)),
$$

and $B_1, B_2, d, i, j$ are homomorphisms between cohomology groups induced from certain natural sections.

From this construction, $V_0, V_1$ naturally define vector bundles over $\hat{M}^m$ which are denoted by $V_0, V_1$, respectively. The above $\alpha, \beta$ in (4.3) are interpreted as homomorphisms between vector bundles, and the universal family $E$ is given by $\text{Ker} \beta / \text{Im} \alpha$.

When we prove that the $\zeta$-stability corresponds to the $m$-stability in Definition 1.1, it is crucial to observe that the sheaf $O_C(-m - 1)$ corresponds to the data $V_0 = \mathbb{C}^m, V_1 = \mathbb{C}^{m+1}, W = 0, d = 0$, and

$$
B_1 = \begin{bmatrix} 1_m & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 & 1_m \end{bmatrix},
$$

where $1_m$ is the identity matrix of size $m$. We denote these data by $C_m$ as above.
4.2. Tangent complex

From the construction, the tangent space is the middle cohomology group of the complex

\[
\begin{align*}
\text{Hom}(V_0, V_1) & 
\oplus 
\text{Hom}(V_0, V_0) 
\oplus 
\text{Hom}(V_1, V_0) 
\oplus 
\text{Hom}(V_1, V_1) 
\oplus 
\text{Hom}(W, V_0) 
\oplus 
\text{Hom}(V_1, W) 
\end{align*}
\]

\[
\xrightarrow{i} \quad \oplus \quad \text{C}^2 \otimes \text{Hom}(V_1, V_0) \xrightarrow{\text{d} \mu} \text{Hom}(V_1, V_0)
\]

with

\[
\begin{bmatrix}
\xi_0 \\
\xi_1
\end{bmatrix} = \begin{bmatrix}
d\xi_0 - \xi_1 d \\
B_1 \xi_1 - \xi_0 B_1 \\
B_2 \xi_1 - \xi_0 B_2 \\
\xi_0 i \\
- j \xi_1
\end{bmatrix}, \quad (d \mu) = \begin{bmatrix}
d \bar{d} \\
\bar{B}_1 \\
\bar{B}_2 \\
\bar{i} \\
\bar{j}
\end{bmatrix} = \begin{bmatrix}
B_1 d \bar{B}_2 + B_1 \bar{d} B_2 + \bar{B}_1 d B_2 \\
- B_2 d \bar{B}_1 - B_2 \bar{d} B_1 - \bar{B}_2 d B_1 \\
+i j + i j
\end{bmatrix}
\]

where \(d \mu\) is the differential of \(\mu\) and \(i\) is the differential of the group action.

We remark that \(d \mu\) is surjective and \(i\) is injective by the above remark if \(X\) is \(\zeta\)-stable.

4.3. A modified quiver

We fix the vector space \(W\) with \(\dim W = r \neq 0\). We define a new quiver with three vertexes 0, 1, \(\infty\). We write two arrows from 1 to zero corresponding to the data \(B_1, B_2\), and one arrow from zero to 1 corresponding to the data \(d\). Instead of writing one arrow from \(\infty\) to zero, we write \(r\)-arrows. Similarly we write \(r\)-arrows from 1 to \(\infty\). And instead of putting \(W\) at \(\infty\), we replace it with the one-dimensional space \(\mathbb{C}\) on \(\infty\). We denote it by \(V_{\infty}\). It means that instead of considering the homomorphism \(i\) from \(W\) to \(V_0\), we take \(r\)-homomorphisms \(i_1, i_2, \ldots, i_r\) from \(V_{\infty}\) to \(V_0\) by taking a base of \(W\) (see Figure 2).

We consider the full subcategory of the abelian category of representations of the new quiver with the relation, consisting of representations such that \(\dim V_{\infty} = 0\) or 1. An object can be considered as a representation of the original quiver with \(\dim W = 0\) or \(\dim W = r\), according to \(\dim V_{\infty} = 0\) or 1. Note that we do not allow a representation of the original quiver with \(\dim W \neq r, 0\).

![Figure 2. Modified quiver](image-url)
It is also suitable to modify the stability condition for representations for the new quiver. Let \((\zeta_0, \zeta_1, \zeta_\infty) \in \mathbb{Q}^3\). For a representation \(X\) of the modified quiver, let us denote the underlying vector spaces by \(X_0, X_1, X_\infty\). We define the rank, degree, and slope by

\[
\begin{align*}
\text{rank } X &: = \dim X_0 + \dim X_1 + \dim X_\infty, \\
\zeta \cdot \text{dim } X &: = \zeta_0 \dim X_0 + \zeta_1 \dim X_1 + \zeta_\infty \dim X_\infty, \\
\theta(X) &: = \frac{\zeta \cdot \text{dim } X}{\text{rank } X},
\end{align*}
\]

where \(\theta(X)\) is defined only when \(X \neq 0\). We consider only the case \(\dim X_\infty = 0\) or 1 as before. We say that \(X\) is \(\theta\)-semistable if we have

\[
\theta(S) \leq \theta(X)
\]

for any subrepresentation \(0 \neq S\) of \(X\). We say that \(X\) is \(\theta\)-stable if the inequality is strict unless \(S = X\). If \(\theta(X) = 0\), \(\theta\)-(semi)stability is equivalent to \(\zeta\)-(semi)stability. In fact, if a subrepresentation \(S\) has \(S_\infty = 0\), then \(\theta(S) \leq 0\) is equivalent to \(\zeta_0 \dim S_0 + \zeta_1 \dim S_1 \leq 0\). If a subrepresentation \(T\) has \(T_\infty = \mathbb{C}\), then \(\theta(T) \leq 0\) is equivalent to \(\zeta_0 \text{codim } T_0 + \zeta_1 \text{codim } T_1 \geq 0\).

The \(\theta\)-stability is unchanged even if we add \(c(1, 1, 1) (c \in \mathbb{R})\) to \((\zeta_0, \zeta_1, \zeta_\infty)\). Therefore once we fix \(\dim X_0, \dim X_1, \dim X_\infty\), we can always achieve the condition \(\theta(X) = 0\) without the changing stable objects.

4.4. Wall-crossing

Let us fix a wall \(\{ \zeta \mid m\zeta_0 + (m+1)\zeta_1 = 0, \zeta_0 < 0 \}\) and a parameter \(\zeta^0 = (\zeta^0_0, \zeta^0_1)\) from the wall. We take \(\zeta^+, \zeta^-\) sufficiently close to \(\zeta^0\) with

\[
1 \gg m\zeta^+_0 + (m+1)\zeta^+_1 > 0, \quad -1 \ll m\zeta^-_0 + (m+1)\zeta^-_1 < 0
\]

(see Figure 3). Then \(\zeta^-\) is nothing but the parameter \(\zeta\), which appeared in Theorem 4.2 corresponding to the \(m\)-stability. On the other hand, we also know that \(\zeta^+\) corresponds to the \((m+1)\)-stability by the determination of the chamber structure in [22, Section 2].

\[
\begin{align*}
\zeta_0 + \zeta_1 &= 0, \\
m\zeta_0 + (m+1)\zeta_1 &= 0, \\
\zeta^0 = (\zeta^0_0, \zeta^0_1), \\
\zeta^+ = (\zeta^+_0, \zeta^+_1), \\
\zeta^- = (\zeta^-_0, \zeta^-_1).
\end{align*}
\]

Figure 3. Wall-crossing
Let us define the scheme $\hat{M}^{m,m+1}$ as the GIT quotient $\hat{M}_{c_0}$ with respect to the $\zeta_0^0$-semistability.

From [22] it follows that $\hat{M}^{m,m+1}$ is the $S$-equivalence classes of $(m, m+1)$-semistable sheaves set-theoretically, where we have the following.

**Definition 4.6**

(a) A framed sheaf $(E, \Phi)$ on $\hat{P}^2$ is called $(m, m+1)$-semistable if

1. $\text{Hom}(E, \mathcal{O}_C(-m-2)) = 0$,
2. $\text{Hom}(\mathcal{O}_C(-m), E) = 0$, and
3. $E$ is torsion free outside $C$.

(b) A framed sheaf $(E, \Phi)$ on $\hat{P}^2$ is called $(m, m+1)$-stable if it is either $\mathcal{O}_C(-m-1)$ (with the trivial framing) or both $m$-stable and $(m+1)$-stable; that is, we have $\text{Hom}(E, \mathcal{O}_C(-m)) = 0$ and $\text{Hom}(\mathcal{O}_C(-m), E) = 0$ instead of (1), (2).

(c) A $(m, m+1)$-semistable framed sheaf $(E, \Phi)$ has a filtration $0 = E_0 \subset E_1 \subset \cdots \subset E_N = E$ such that $E_i/E_{i-1}$ is $(m, m+1)$-stable with the induced framing from $\Phi$. We say that $(m, m+1)$-semistable framed sheaves $(E, \Phi)$ and $(E', \Phi')$ are $S$-equivalent if there exists an isomorphism from $\bigoplus_i E_i/E_{i-1}$ to $\bigoplus_j E'_j/E'_{j-1}$ respecting the framing in the $(m, m+1)$-stable factors.

The main result [22, Theorem 1.5] was stated for $m$-stable framed sheaves, but it can be generalized to the case of $(m, m+1)$-stable framed sheaves. It follows from [22, Propositions 4.1, 4.2] that $X$ is $\zeta_0^0$-semistable if and only if it satisfies condition (S2) in [22, Theorem 1.1] and the condition corresponding to (a.1, 2) above. Then the remaining arguments are the same.

Since $\zeta^\pm$-stability implies $\zeta_0^0$-semistability, we have natural morphisms $\xi_m: \hat{M}^m \to \hat{M}^{m,m+1}$, $\xi^+_m: \hat{M}^{m+1} \to \hat{M}^{m,m+1}$. Thus $\hat{M}^m$, $\hat{M}^{m+1}$, and $\hat{M}^{m,m+1}$ form the diagram $(*).

This definition of $\hat{M}^{m,m+1}$ is different from those given in [21] for ordinary moduli spaces without framing, but they are the same at least set-theoretically thanks to the construction in [22, Sections 3.6, 3.7]. It is also possible to show directly that $\xi_m, \xi^+_m$ have structures of stratified Grassmann bundles described there.

From the definition it is clear that $\xi_m, \xi^+_m$ are compatible with projective morphisms $\hat{M}^m \to M_0$, $\hat{M}^{m,m+1} \to M_0$, $\hat{M}^{m+1} \to M_0$ (all denoted by $\hat{\pi}$ before).

The change of the moduli spaces under the wall-crossing is described as follows.

**Proposition 4.7** ([21, Proposition 3.15])

1. If $(E^-, \Phi)$ is $m$-stable, we have an exact sequence

$$0 \to V \otimes C_m \to E^- \to E' \to 0$$

with $V = \text{Hom}(C_m, E^-)$ such that

   (a) $E'$ is $(m, m+1)$-stable,
(b) the induced homomorphism $V \to \text{Ext}^1(E', C_m)$ is injective.

Conversely, if $(E', \Phi)$ is $(m, m + 1)$-stable and a subspace $V \subset \text{Ext}^1(E', C_m)$ is given, $(E^-, \Phi)$, defined by the above exact sequence, is $m$-stable.

(2) If $(E^+, \Phi)$ is $(m + 1)$-stable, we have an exact sequence

$$0 \to E' \to E^+ \to U^\vee \otimes C_m \to 0$$

with $U = \text{Hom}(E^+, C_m)$ such that

(a) $E'$ is $(m, m + 1)$-stable, and
(b) the induced homomorphism $U^\vee \to \text{Ext}^1(C_m, E^')$ is injective.

Conversely, if $(E', \Phi)$ is $(m, m + 1)$-stable and a subspace $U^\vee \subset \text{Ext}^1(C_m, E')$ is given, $(E^+, \Phi)$, defined by the above exact sequence, is $(m + 1)$-stable.

4.5. Computation of Ext-groups

In this subsection, we continue to fix a wall $m \zeta_0 + (m + 1) \zeta_1 = 0, \zeta_0 < 0$.

Take $X = (B_1, B_2, d, i, j)$ defined on $V_0, V_1, W$ such that $\mu(B_1, B_2, d, i, j) = 0$.

We consider the complex

$$\begin{align*}
\text{Hom}(V_0, C_m) \oplus \text{Hom}(V_1, C_{m+1}) & \xrightarrow{\sigma} \mathbb{C}^2 \otimes \text{Hom}(V_1, C_m) \oplus \text{Hom}(W, C_m) \\
\xrightarrow{\tau} \text{Hom}(V_1, C_m) & 
\end{align*}$$

with

$$\sigma \begin{bmatrix} \xi_0 \\ \xi_1 \end{bmatrix} = \begin{bmatrix} \xi_1 d \\ \xi_0 B_1 - [1_m, 0, \xi_1] \\ \xi_0 B_2 - [0, 1_m, \xi_1] \\ \xi_0 i \end{bmatrix},$$

$$\tau \begin{bmatrix} \tilde{d} \\ \tilde{B}_1 \\ \tilde{B}_2 \\ \tilde{i} \end{bmatrix} = [1_m, 0] \tilde{d} B_2 - [0, 1_m] \tilde{d} B_1 + \tilde{i} j + \tilde{B}_1 d B_2 - \tilde{B}_2 d B_1.$$

This complex is constructed as follows. We take the dual of (4.3) and replace the part $\mathbb{C}^2 \otimes V_0^* \otimes \mathcal{O}(-w z) \to V_0^* \otimes \mathcal{O}(-C + \ell_\infty)$ by $V_0^* \otimes \mathcal{O}(C - \ell_\infty)$. We then take the tensor product with $C_m$ and apply $H^*(\mathbb{P}^2, \bullet)$. Therefore when $X$ corresponds to a framed sheaf $(E, \Phi)$, the cohomology groups of the complex are $\text{Ext}^*(E, C_m)$.

**Lemma 4.9**

Suppose that $X$ corresponds to a framed sheaf $(E, \Phi)$.

1. We have $\text{Hom}(E, C_m) \cong \text{Ker} \sigma$, $\text{Ext}^1(E, C_m) \cong \text{Ker} \tau / \text{Im} \sigma$, and $\text{Ext}^2(E, C_m) \cong \text{Coker} \tau$.

2. Suppose further that $X$ is $(m, m + 1)$-semistable. Then $\tau$ is surjective.
Proof

(1) These are already explained.

(2) By the Serre duality, we have \( \text{Ext}^2(C_m, E) = \text{Hom}(C_{m-1}, E) \). But the right-hand side vanishes if \( E \) is \((m, m + 1)\)-semistable. \( \square \)

If \( X \) is \( \zeta^-\)-stable (i.e., \((E, \Phi)\) is \( m\)-stable), we also have \( \text{Ker} \sigma = 0 \). But this does not hold in general if \( X \) is only \((m, m + 1)\)-semistable.

Next we consider the complex

\[
\begin{array}{cccc}
\text{Hom}(C^m, V_0) & \oplus & \text{Hom}(C^m, V_1) \\
\text{Hom}(C^{m+1}, V_0) & \oplus & \text{Hom}(C^{m+1}, V_1) & \rightarrow \\
\end{array}
\]

(4.10)

\[
\begin{array}{cccc}
\oplus & C \otimes \text{Hom}(C^{m+1}, V_0) & \oplus & \text{Hom}(C^{m+1}, W) \\
\end{array}
\]

with

\[
\sigma \left[ \begin{array}{c}
\xi_0 \\
\xi_1 \\
\end{array} \right] = \left[ \begin{array}{cc}
d\xi_0 \\
B_1 \xi_1 - \xi_0 [1_m] & 0 \\
B_2 \xi_1 - \xi_0 [0, 1_m] \\
j \xi_1 \\
\end{array} \right],
\]

\[
\tau \left[ \begin{array}{c}
\bar{d} \\
\bar{B}_1 \\
\bar{B}_2 \\
\bar{j} \\
\end{array} \right] = B_1 \bar{d} [1_m, 0] - B_2 \bar{d} [0, 1_m] + i \bar{j} + B_1 \bar{d} \bar{B}_2 - B_2 \bar{d} \bar{B}_1.
\]

LEMMA 4.11

Suppose that \( X \) corresponds to a framed sheaf \((E, \Phi)\).

(1) We have \( \text{Hom}(C_m, E) \cong \text{Ker} \sigma \), \( \text{Ext}^1(C_m, E) \cong \text{Ker} \tau / \text{Im} \sigma \), and \( \text{Ext}^2(C_m, E) \cong \text{Coker} \tau \).

(2) Suppose further that \( X \) is \((m, m + 1)\)-semistable. Then \( \tau \) is surjective.

Proof

The proof of (1) is the same as in Lemma 4.9, so it is omitted.

For (2) we have \( \text{Ext}^2(C_m, E) \cong \text{Hom}(E, C_{m+1})^\vee \) by the Serre duality. But the right-hand side vanishes if \( E \) is \((m, m + 1)\)-semistable. \( \square \)

If \( X \) is \( \zeta^+\)-stable (i.e., \((E, \Phi)\) is \((m + 1)\)-stable), we also have \( \text{Ker} \sigma = 0 \). But this does not hold in general if \( X \) is only \((m, m + 1)\)-semistable.

COROLLARY 4.12

Let \( Q^{ss}(\zeta^0) \) be the open subscheme of \( Q \) consisting of \( \zeta^0\)-semistable, that is, \((m, m + 1)\)-semistable objects. The differential \( d_\mu \) is surjective on \( Q^{ss}(\zeta^0) \). Hence \( Q^{ss}(\zeta^0) \) is smooth.
**Proof**

Since the surjectivity of $d\mu$ is an open condition, it is enough to check the assertion when $X$ is a direct sum of $\zeta^0$-stable objects. As explained in Definition 4.6, we have $X = X^0 \oplus C_m^p$, where $X^0$ is $\zeta^0$-stable with $X_\infty \neq 0$ and $p \geq 0$. Then the tangent complex (4.4) decomposes into four parts: the tangent complex for $X^0$, the sum of $p$-copies of the complex (4.8) for $X^0$, the sum of $p$-copies of the complex (4.10) for $X^0$, and the sum of $p^2$-copies of the tangent complex for $C_m$.

The differential of $d\mu$ for $X^0$ is surjective since $X^0$ is $\zeta^0$-stable by [22, Lemma 2.4]. The surjectivity of $\tau$ for (4.8) and (4.10) was proved in Lemmas 4.9 and 4.11, respectively. The surjectivity of $d\mu$ for $C_m$ follows from either [22, Lemma 2.4], Lemma 4.9, or Lemma 4.11 since $C_m$ is $(-1/m, 1/(m + 1))$-stable.

□

5. Enhanced master spaces

A naive idea to show the weak wall-crossing formula (i.e., Theorem 1.5) is to compare the intersection products on $\hat{M}^m(c)$ and $\hat{M}^{m+1}(c)$ through the diagram (*). Such an idea works when $\hat{M}^m(c)$, $\hat{M}^{m+1}(c)$ are replaced by moduli spaces of stable rank 2 torsion-free sheaves over a surface with $p_g = 0$ with respect to two polarizations separated by a wall which is good (see [3]; see also [7]).

However, the idea does not work since the morphisms $\xi_m$, $\xi^+_m$ are much more complicated in our current situation, basically because dimensions of vector spaces $V$, $U$ in Proposition 4.7 can be arbitrary. We use a refinement of the idea, due to Mochizuki [14], which was used to study the wall-crossing formula for moduli spaces of higher ranks stable sheaves. It consists of two parts.

(Ma) Consider a pair of a sheaf and a full flag in the sheaf cohomology group.

(Mb) Use the fixed point formula for the $\mathbb{C}^*$-equivariant cohomology on Thaddeus’s master space.

In this section we describe the part (Ma). The results are straightforward modifications of those in [14, Section 4], possibly except one in Section 5.4.

We remark that Yamada [29] also used moduli spaces of pairs of a sheaf and a full flag in the sheaf cohomology group to study wall crossing of moduli spaces of higher-rank sheaves.

We continue to fix $m$ and choose parameters $\zeta^0$, $\zeta^\pm$ as in Section 4. We fix a dimension vector $v = (v_0, v_1, 1)$ and define $\zeta^0_\infty$ so that the normalization condition $\zeta^0_0 v_0 + \zeta^1_0 v_1 + \zeta^0_\infty = 0$ is satisfied.

5.1. Framed sheaves with flags in cohomology groups

Let $((E, \Phi), F^\bullet)$ be a pair of a framed sheaf and a full flag $F^* = (0 = F^0 \subset F^1 \subset \cdots \subset F^{N-1} \subset F^N = V_1(E))$ ($N = \dim V_1(E)$). Let $\ell$ be an integer between zero and $N$.
DEFINITION 5.1
An object $((E, \Phi), F^\bullet)$ is called $(m, \ell)$-stable if the following three conditions are satisfied.

1. $(E, \Phi)$ is $(m, m+1)$-semistable.
2. For a subsheaf $\mathcal{G} \subset E$ isomorphic to $C^p_m$ with $p \in \mathbb{Z}_{>0}$, we have $V_1(\mathcal{G}) \cap F^\ell = 0$.
3. For a subsheaf $\mathcal{G} \subset E$ such that the quotient $E/\mathcal{G}$ is isomorphic to $C^p_m$ with $p \in \mathbb{Z}_{>0}$, we have $F^\ell \not\subset V_1(\mathcal{G})$.

This notion makes a bridge between the $m$-stability and the $(m+1)$-stability by the following observation: If $\ell = 0$ (resp., $\ell = N$), then $(m, \ell)$-stability of $((E, \Phi), F^\bullet)$ is equivalent to $m$-stability (resp., $(m+1)$-stability) of $(E, \Phi)$ (see Proposition 4.7).

PROPOSITION 5.2 ([14, COROLLARY 4.2.5])
We have a smooth fine moduli scheme $\tilde{M}^{m,\ell}(c)$ of $(m, \ell)$-stable objects $((E, \Phi), F^\bullet)$ with $\text{ch}(E) = c$. There is a projective morphism $\tilde{M}^{m,\ell}(c) \to \tilde{M}_0(p_*(c))$.

The proof is given in Section 5.2.

Let $E$ be the universal sheaf over $\tilde{\mathbb{P}}^2 \times \tilde{M}^{m,\ell}(c)$, and let $q_1, q_2$ be the projection to the first and second factors of $\tilde{\mathbb{P}}^2 \times \tilde{M}^{m,\ell}(c)$, respectively, as before. As well as the vector bundle $\mathcal{V}_1 \equiv \mathcal{V}_1(E) := R^1q_2\ast(E \otimes q_1^*O(C - \ell \infty))$, we also have the universal family $\mathcal{F}^\bullet = (0 = F^0 \subset F^1 \subset \cdots \subset F^{N-1} \subset F^N = \mathcal{V}_1)$ of flags of vector bundles over $\tilde{M}^{m,\ell}(c)$.

For $\ell = 0$ or $N$, the preceding remark implies that $\tilde{M}^{m,0}(c), \tilde{M}^{m,N}(c)$ are the full flag bundles $\text{Flag}(\mathcal{V}_1, \mathcal{N})$ associated with vector bundles $\mathcal{V}_1$ over $\tilde{M}^m(c)$, $\tilde{M}^{m+1}(c)$, respectively. Here $\mathcal{N} = \{1, \ldots, N\}$ and the notation $\text{Flag}(\mathcal{V}_1, \mathcal{N})$ means that the flag is indexed by the set $\mathcal{N}$. This notation becomes useful when we consider the fixed points in the enhanced master space.

5.2. Proof of Proposition 5.2
Let us rephrase the $(m, \ell)$-stability in the quiver description.

We consider a pair $(X, F^\bullet) = ((B_1, B_2, d, i, j), F^\bullet)$ of $X \in \mu^{-1}(0)$ and a flag $F^\bullet = (0 = F^0 \subset F^1 \subset \cdots \subset F^{N-1} \subset F^N = \mathcal{V}_1)$ of $\mathcal{V}_1$ with $\dim(F^i/F^{i-1}) = 0$ or 1. In Definition 5.1 we have assumed that $F^\bullet$ is a full flag, that is, $\dim(F^i/F^{i-1}) = 1$, but we slightly generalize it for notational simplicity.

In terms of a quiver representation, Definition 5.1 is expressed as follows.

DEFINITION 5.3
For $0 \leq \ell \leq N$, we say that $(X, F^\bullet)$ is $(m, \ell)$-stable if the following conditions are satisfied:

1. $X$ is $\zeta^0$-semistable,
(2) for a nonzero submodule \(0 \neq S \subset X\) with \(\zeta^0 \cdot \dim S / \rank S = 0\) and \(S_\infty = 0\), we have \(F^\ell \cap S_1 = 0\), and
(3) for a proper submodule \(S \subset X\) with \(\zeta^0 \cdot \dim S / \rank S = 0\) and \(S_\infty = \mathbb{C}\), we have \(F^\ell \not\subset S_1\).

The equivalence of (2) and (3) and 5.1(2), (3) is an immediate consequence of [22, Theorem 2.13, Proposition 5.3].

If \(\ell = 0\) (resp., \(\ell = N\)), then \((m, \ell)-\text{stability}\) is equivalent to the \(\zeta^-\)-stability (resp., \(\zeta^+\)-stability) of \(X\) (see Proposition 4.7).

The idea of the proof of Proposition 5.2 is to relate the above condition to a usual stability condition for a linearization on the product of \(\mu^{-1}(0)\) and the flag variety with respect to the group action of \(G\). It is the tensor product of linearizations on \(\mu^{-1}(0)\) and the flag variety. For \(\mu^{-1}(0)\), we take one as in Section 4.1. On the flag variety, we take \(\bigotimes (\det F_i)^{-n_i}\) for \(n_i \in \mathbb{Q}^N_{>0}\), where \(F_i\) is the \(i\)th universal bundle (see [14, Section 4.2]). Then we have a natural projective morphism to \(\mu^{-1}(0)/G = M_0(p_*(c))\) as before.

The corresponding stability condition is expressed as before, but an extra term for flags is added to \(\theta\) (cf. [16, Chapter 4, Section 4]). For a nonzero graded submodule \(S \subset X\), we define
\[
\mu_{\zeta, n}(S) := \frac{\zeta \cdot \dim S + \sum n_i \dim (S \cap F^i)}{\rank S}.
\]
We say that \((X, F^\bullet)\) is \((\zeta, n)-(semi)stable\) if
\[
\mu_{\zeta, n}(S)(\leq)\mu_{\zeta, n}(X)
\]
holds for any nonzero proper submodule \(0 \neq S \subset X\). Here \(\leq\) means \(\leq\) for the semistable case and \(<\) for the stable case. We say that \((X, F^\bullet)\) is strictly \((\zeta, n)-\text{semistable}\) if it is \((\zeta, n)-\text{semistable}\) and not \((\zeta, n)-\text{stable}\).

A standard argument shows the following.

**Lemma 5.4**

If \((X, F^\bullet), (Y, G^\bullet)\) are \((\zeta, n)-\text{stable}\) and have the same \(\mu_{\zeta, n}\)-value, a nonzero homomorphism \(\xi : X \to Y\) with \(\xi(F^i) \subset G^n\) must be an isomorphism.

We take \(N = \dim V_1\) so that \(F^\bullet\) is a full flag of \(V_1\). Consider the following conditions when \(\ell \neq 0\):

(5.5a) \(\zeta_0 v_0 + \zeta_1 v_1 + \zeta_\infty = 0\),

(5.5b) \(n_k > \rank X \sum_{i=k+1}^N in_i > 0\) for \(k = 1, \ldots, N - 1\),

(5.5c) \(\max_{S \subset V} \frac{(\zeta^0 - \zeta) \cdot \dim S}{\rank S} + \sum_{i=1}^N in_i < \min_{S \subset V} \frac{\zeta^0 \cdot \dim S}{\rank S}\).
Assume (5.5). Then the following hold.

**Lemma 5.6 ([14, Proposition 4.2.4])**

**Assume (5.5). Then the following hold.**

1. The \((m, \ell)\)-stability is equivalent to the \((\zeta, n)\)-stability.
2. The \((\zeta, n)\)-semistability automatically implies the \((\zeta, n)\)-stability.

Lemma 5.4 also implies that \((\zeta, n)\)-stable objects have the trivial stabilizer. Therefore we have Proposition 5.2 from this lemma.

From the construction the universal family \(\mathcal{F}^* = (0 = \mathcal{F}^0 \subset \mathcal{F}^1 \subset \cdots \subset \mathcal{F}^{N-1} \subset \mathcal{F}^N = \mathcal{V}_1)\) we have the descent of the universal flag over \(\text{Flag}(V_1, N)\). Using descents of \(V_0, V_1\) (which are denoted by \(\mathcal{V}_0, \mathcal{V}_1\)) in the complex (4.3), we also get the universal family \(\mathcal{E}\) over \(\mathbb{P}^2 \times \hat{M}^m(c)\).

**Proof of Lemma 5.6**

Suppose that \(S \subset X\) is a nonzero submodule with \(\zeta^0 \cdot \dim S = 0, S_\infty = 0\). Then \(\dim S = p(m, m + 1, 0)\) for some \(p \in \mathbb{Z}_{>0}\). Then \(\mu_{\zeta,n}(S) \leq \mu_{\zeta,n}(X)\) means

\[
\frac{1}{2m + 1} \sum_{i=1}^{\ell} n_i \dim(S_1 \cap F^i) \leq \sum_{i=1}^{\ell} n_i.
\]

By (5.5d, e), this holds if and only if \(S_1 \cap F^\ell = 0\). Moreover, the equality never holds.

Next, suppose that \(S \subset X\) is a proper submodule with \(\zeta^0 \cdot \dim S = 0, S_\infty = \mathbb{C}\). Then \(\dim X/S = p(m, m + 1, 0)\) for some \(p \in \mathbb{Z}_{>0}\). Then \(\mu_{\zeta,n}(S) \leq \mu_{\zeta,n}(X)\) means

\[
\frac{1}{2m + 1} \sum_{i=1}^{\ell} n_i \dim(F^i/S_1 \cap F^i) \geq \sum_{i=1}^{\ell} n_i.
\]
By (5.5d, e), this holds if and only if $F^i / S_1 \cap F^i \neq 0$ for some $i = 1, \ldots, \ell$, that is, $F^\ell \not\subseteq S_1$. Moreover, the equality never holds.

Now let us start the proof. Suppose that $(X, F^\bullet)$ is $(\zeta, n)$-semistable. Then by (5.5c), $\mu_{\zeta, n}(S) \leq \mu_{\zeta, n}(X)$ implies $\zeta^0 \cdot \text{dim } S \leq 0$; that is, $X$ is $\zeta^0$-semistable. Then the above consideration shows that $(X, F^\bullet)$ is $(m, \ell)$-stable and $(\zeta, n)$-stable.

Conversely, suppose that $(X, F^\bullet)$ is $(m, \ell)$-stable. We want to show that $\mu_{\zeta, n}(S)^2 \leq \mu_{\zeta, n}(X)^2$ for any nonzero proper submodule $S$. Thanks to (5.5c), it is enough to check this inequality for $S$ with $\zeta^0 \cdot \text{dim } S = 0$. We have either $S_\infty = 0$ or $S_\infty = \mathbb{C}$, and the above consideration shows that the inequality holds. □

REMARK 5.7

A closer look of the argument shows that it is enough to assume (5.5c) for $S \subseteq V$ satisfying either of the following:

1. $\zeta^0 \cdot \text{dim } S > 0$ and $\mu_{\zeta, n}(S) \leq \mu_{\zeta, n}(X)$,
2. $\zeta^0 \cdot \text{dim } S < 0$ and $\mu_{\zeta, n}(S) \geq \mu_{\zeta, n}(X)$.

5.3. Oriented sheaves with flags in cohomology groups

The following variant of objects in Section 5.2 will show up during our analysis for the enhanced master space.

DEFINITION 5.8

(1) Let $(E, F^\bullet)$ be a pair of a sheaf and a full flag $F^\bullet = (0 = F^0 \subseteq F^1 \subseteq \cdots \subseteq F^{N-1} \subseteq F^N = V_1(E))$ $(N = \text{dim } V_1(E))$. We say that $(E, F^\bullet)$ is $(m, +)$-stable if the following two conditions are satisfied:

  a. $E \cong C_0^m$ for $p \in \mathbb{Z}_{>0}$,
  b. for a proper subsheaf $\mathcal{G} \subset E$ isomorphic to $C_0^m$ with $q \in \mathbb{Z}_{>0}$, we have $V_1(\mathcal{G}) \cap F^1 = 0$.

(2) For $(m_0, m_1) \in \mathbb{Z}^2 \setminus \{(0, 0)\}$, an orientation of $(E, F^\bullet)$ is an isomorphism $\rho: \det H^1(E) \otimes m_0 \otimes \det H^1(E(C)) \otimes m_1 \cong \mathbb{C}$. We set $D := mm_0 + (m + 1)m_1$.

(3) An oriented $(m, +)$-stable object means an $(m, +)$-stable object $(E, F^\bullet)$ together with an orientation.

We will choose $(m_0, m_1)$ later when we define the enhanced master space. At this stage we only need to have $D > 0$. Since the orientation is used frequently, we use the notation $L(E) := \det H^1(E(-E_\infty)) \otimes m_0 \otimes \det H^1(E(C - E_\infty)) \otimes m_1$ for a sheaf $E$ on $\mathbb{P}^2$. (In the above case, $E$ is supported on $C$ and the twisting by $\mathcal{O}(-E_\infty)$ is unnecessary.) If $E$ is a universal family for some moduli stack, we denote the corresponding line bundle by $L(E)$. Note that we deal only with those sheaves given by quiver representations; we have vanishing of $H^0$ and $H^2$. 
We show that we have a moduli stack $\tilde{M}^{m,+}(pe_m)$ of oriented $(m, +)$-stable objects with $\text{ch}(E) = pe_m$ with the universal family $(\mathcal{E}, \mathcal{F}^\bullet)$, where $\mathcal{F}^\bullet = (0 = \mathcal{F}^0 \subset \mathcal{F}^1 \subset \cdots \subset \mathcal{F}^{N-1} \subset \mathcal{F}^N = V_1)$ is a flag of vector bundles over $\tilde{M}^{m,+}(pe_m)$.

In the following proposition we identify $\tilde{M}^{m,+}(pe_m)$ with a quotient stack related to the Grassmann variety $\text{Gr}(m+1, p)$ of $p$-dimensional quotients of $V_1(C_m)^* = H^1(C_m(C))^* = \mathbb{C}^{m+1}$. Let us fix the notation. Let $Q$ denote the universal quotient bundle over $\text{Gr}(m+1, p)$, let $\det Q$ be its determinant line bundle, and let $(\det Q)^{\otimes D}$ be its $D$th tensor power. Let $\pi_G : ((\det Q)^{\otimes D})^\times \rightarrow \text{Gr}(m+1, p)$ be the associated $\mathbb{C}^*$-bundle. Let $\mathcal{O}_{\text{Gr}(m+1, p)} \rightarrow V_1(C_m) \otimes Q$ be the homomorphism obtained from the universal homomorphism $V_1(C_m)^* \rightarrow Q$.

**PROPOSITION 5.9**

1. Forgetting $F^i$ for $i \neq 1$, we identify $\tilde{M}^{m,+}(pe_m)$ with the total space of the flag bundle $\text{Flag}(V_1/F^1, N \setminus \{1\})$, where the base is isomorphic to the quotient stack

\[ ((\det Q)^{\otimes D})^\times / \mathbb{C}^*, \]

where $\mathbb{C}^*$ acts by the fiber-wise multiplication with weight $-pD$.

2. Let $C_s^* = \text{Spec} \mathbb{C}[s, s^{-1}]$ be a copy of $\mathbb{C}^*$, and let $\mathbb{C}^* \rightarrow C^*_s$ be the homomorphism given by $t \mapsto t^{-pD} = s$. It induces an étale and finite morphism $h : ((\det Q)^{\otimes D})^\times / C^* \rightarrow ((\det Q)^{\otimes D})^\times / C^*_s = \text{Gr}(m+1, p)$ of degree $1/pD$. The vector bundles $V_1$, $\mathcal{F}^1$ and the universal sheaf $\mathcal{E}$ are related to objects on $\text{Gr}(m+1, p)$ by

\[ V_1 \otimes (\mathcal{F}^1)^* = h^* (V_1(C_m) \otimes Q), \quad (\mathcal{F}^1)^{\otimes -pD} = h^* ((\det Q)^{\otimes D}), \]

\[ \mathcal{E} \otimes (\mathcal{F}^1)^* = (\text{id} \times h)^* (C_m \otimes Q), \]

and the inclusion $(\mathcal{F}^1 \rightarrow V_1)$ is $h^* (\mathcal{O}_{\text{Gr}(m+1, p)} \rightarrow V_1(C_m) \otimes Q) \otimes \text{id}_{\mathcal{F}^1}$.

The proof is given in the next subsection.

**5.4. Proof of Proposition 5.9**

Since $F^i$ with $i > 1$ does not appear in the stability condition, the moduli stack has a structure of the flag bundle $\text{Flag}(V_1/F^1, N \setminus \{1\})$ over the moduli stack parameterizing $(X, F^1)$. Here $V_1$ is a vector bundle over the moduli stack, and $\mathcal{F}^1$ is its line subbundle, coming from $V_1$ and $F^1$, respectively.

Next, we determine the moduli stack parameterizing $(X, F^1)$. Since we already know $X \cong C_m^{\otimes p}$, the remaining parameter is only a choice of $F^1$, which is a 1-dimensional subspace in $V_1(X) \cong V_1(C_m) \otimes \mathbb{C}^p$. We have an action of the stabilizer $\text{GL}_p(\mathbb{C})$ of $X$. The above stability condition means that $F^1$, viewed as a nonzero homomorphism $V_1(C_m)^* \rightarrow \mathbb{C}^p$, is surjective. Therefore the moduli stack is

\[ (\{ \xi \in \mathbb{P}(\text{Hom}(V_1(C_m)^*, \mathbb{C}^p)) \mid \xi \text{ is surjective} \} \times \mathbb{C}^*) / \text{GL}_p(\mathbb{C}), \]
where the action of $\text{GL}_p(\mathbb{C})$ on $\mathbb{C}^*$ is given by $g \cdot u = (\det g)^D u$ with $D = mm_0 + (m + 1)m_1$.

We consider (5.10) as
\[
(5.11) \quad \{ \{ \xi \in \text{Hom}(V_1(C_m)^*, \mathbb{C}^p) \mid \xi \text{ is surjective} \} \times \mathbb{C}^* / \text{GL}_p(\mathbb{C}) \times \mathbb{C}^* ,
\]
where $\mathbb{C}^* \ni t$ acts by $(\xi, u) \mapsto (t\xi, u)$. If we take the quotient by $\text{GL}_p(\mathbb{C})$ first, we get $L^\times = L \setminus (0\text{-section})$, where $L = (\det \mathcal{Q})^D$, the $D$th tensor power of the determinant line bundle $\det \mathcal{Q}$ of the universal quotient over the $\text{Gr}(m+1, p)$. Since $\mathbb{C}^* \ni t$ acts by
\[
(5.12) \quad (t\xi, u) = t \text{id}_{\mathbb{C}^p} \cdot (\xi, t^{-pD} u),
\]
it is the fiber-wise multiplication with weight $-pD$ on the quotient $L^\times$. Thus the moduli stack parameterizing $(X, F^1)$ is isomorphic to the quotient stack $[L^\times / \mathbb{C}^*]$.

This action factors through $\rho: \mathbb{C}^* \to \mathbb{C}^*$ given by $t \mapsto s = t^{-pD}$, where the latter action is free on $L^\times$ and the quotient is $\text{Gr}(m+1, p)$. Let us denote the latter $\mathbb{C}^*$ by $\mathbb{C}^*_s$. Then the stack $L^\times / \mathbb{C}^*_s$ is represented by $\text{Gr}(m+1, p)$, as $L^\times$ is a principal $\mathbb{C}^*_s$-bundle. Since a $\mathbb{C}^*$-bundle induces a $\mathbb{C}^*_s$-bundle by taking the quotient by $\text{Ker}\rho \cong \mathbb{Z}/pd$, we have a morphism $H: L^\times / \mathbb{C}^* \to L^\times / \mathbb{C}^*_s = \text{Gr}(m+1, p)$ between stacks. It is étale and finite of degree $1/pD$.

Let us identify the pair $(\mathcal{F}^1 \subset \mathcal{V}_1)$ of the vector bundle $\mathcal{V}_1$ and its line subbundle $\mathcal{F}^1$ over the moduli stack in the description $[L^\times / \mathbb{C}^*]$. In the description (5.10), it is the descent of the restriction of $\mathcal{O}_{\mathbb{P}(-1) \boxtimes \mathcal{O}_{\mathbb{C}^*} \subset \mathcal{V}_1(C_m) \otimes \mathbb{C}^p \otimes \mathcal{O}_{\mathbb{C}^*}}$ with respect to the natural $\text{GL}_p(\mathbb{C})$-action, where $\mathbb{P} = \mathbb{P}(\text{Hom}(V_1(C_m)^*, \mathbb{C}^p))$. Then in the description (5.11), it becomes the descent of the pair $\mathcal{O}_V \subset V_1(C_m) \otimes \mathbb{C}^p \otimes \mathcal{O}_V$, where $\text{GL}_p(\mathbb{C})$ acts naturally and the $\mathbb{C}^*$-action is twisted by the weight $-1$ action on the first factor $\mathcal{O}_V$. Here $V = \{ \xi \in \text{Hom}(V_1(C_m)^*, \mathbb{C}^p) \mid \xi \text{ is surjective} \} \times \mathbb{C}^*$. Finally, in the description $[L^\times / \mathbb{C}^*]$, it is the descent of
\[
(\mathcal{O}_{L^\times} \subset \pi^*_G(V_1(C_m) \otimes \mathcal{Q})) ,
\]
where the $\mathbb{C}^*$-action is twisted by weight $-1$ on both $\mathcal{O}_{L^\times}$ and $\pi^*_G(V_1(C_m) \otimes \mathcal{Q})$. Here $\pi_G: L^\times \to \text{Gr}(m+1, p)$ is the projection. The twist on the second factor $\pi^*_G(V_1(C_m) \otimes \mathcal{Q})$ comes from the term $t \text{id}_{\mathbb{C}^p}$ in (5.12).

From the above description of $\mathcal{V}_1$, we have $\mathcal{V}_1 \otimes (\mathcal{F}^1)^* = h^*(V_1(C_m) \otimes \mathcal{Q})$. On the other hand, $(\mathcal{F}^1)^{\otimes -pD}$ is the descent of $\mathcal{O}_{L^\times}$ with the $\mathbb{C}^*$-action twisted by weight $pD$. The action factors through the $\mathbb{C}^*_s$-action, and it is twisted by weight $-1$. Therefore it descends to $L$ on $\text{Gr}(m+1, p)$.

5.5. 2-Stability condition

This subsection is devoted to preliminaries for a study of enhanced master spaces.

We consider the following condition on $n$:
\[
(5.13) \quad \sum_{i=1}^N k_i n_i \neq 0 \quad \text{for any} \quad (k_1, \ldots, k_N) \in \mathbb{Z}^N \setminus \{0\} \quad \text{with} \quad |k_i| \leq 2N^2 .
\]

Our flag $F^\bullet$ of $V_1$ again may have repetition, but assume that $\dim(F^i/F^{i-1}) = 0$ or $1$, as before.
LEMMA 5.14
Assume that \( \zeta \) satisfies \((m + 1)\zeta_0 + (m + 2)\zeta_1 < 0\), \((m - 1)\zeta_0 + m\zeta_1 > 0\), and assume that \( n \) satisfies (5.13). If \((X, F^\bullet)\) is strictly \((\zeta, n)\)-semistable, then there exists a submodule \( 0 \neq S \subseteq X \) such that

1. \( \mu_{\zeta, n}(S, S_1 \cap F^\bullet) = \mu_{\zeta, n}(X, F^\bullet) \),
2. \((S, S_1 \cap F^\bullet)\) and \((X/S, F^\bullet/S_1 \cap F^\bullet)\) are \((\zeta, n)\)-stable.

Moreover, the submodule \( S \) is unique except when \((X, F^\bullet)\) is the direct sum \((S, S_1 \cap F^\bullet) \oplus (X/S, F^\bullet/S_1 \cap F^\bullet)\). In this case the other choice of the submodule is \(X/S\).

Proof
Take a submodule \( S \) violating the \((\zeta, n)\)-stability of \( X \). Then we have (1). Moreover, \((S, S_1 \cap F^\bullet)\) and \((X/S, F^\bullet/S_1 \cap F^\bullet)\) are \((\zeta, n)\)-semistable. We have either \( S_\infty = 0 \) or \((X/S)_\infty = 0\).

Assume that either \((S, S_1 \cap F^\bullet)\) or \((X/S, F^\bullet/S_1 \cap F^\bullet)\) is strictly \((\zeta, n)\)-semistable. Then we have a filtration \( 0 = X^0 \subseteq X^1 \subseteq X^2 \subseteq X^3 = X \) with \( \mu_{\zeta, n}(X^a/X^{a-1}, F^\bullet_a) = \mu_{\zeta, n}(X, F^\bullet) \) for \( a = 1, 2, 3 \), where \( F^\bullet_a \) denote the induced filtration on \( X^a/X^{a-1} \) from \( F^\bullet \).

Among \( X^a/X^{a-1} \) \((a = 1, 2, 3)\), one of them has \( C \) and two of them have zero at the \( \infty \)-component. Assume that \( X^1 \) has \( C \) at the \( \infty \)-component for brevity, as the following argument can be applied to the remaining cases.

We have \( \dim X^2/X^1 = p_2(m, m + 1, 0) \), \( \dim X^3/X^2 = p_3(m, m + 1, 0) \) for some \( p_2, p_3 \in \mathbb{Z}_{>0} \). Then \( \mu_{\zeta, n}(X^2/X^1, F^\bullet_2) = \mu_{\zeta, n}(X^3/X^2, F^\bullet_3) \) implies

\[
\sum n_i \left( \frac{\dim(F^\bullet_i)}{p_2} - \frac{\dim(F^\bullet_i)}{p_3} \right) = 0.
\]

By the assumption (5.13), we have \( p_3 \dim(F^\bullet_2) = p_2 \dim(F^\bullet_3) \), and hence

\[(5.15) \quad p_3 \dim(F^\bullet_2/F^\bullet_2) = p_2 \dim(F^\bullet_3/F^\bullet_3) \]

for any \( i \). On the other hand, we have

\[
\dim(F^\bullet_1/F^\bullet_1) + \dim(F^\bullet_2/F^\bullet_2) + \dim(F^\bullet_3/F^\bullet_3) = \dim(F^\bullet_F/F^\bullet_F) = 0 \text{ or } 1
\]

for any \( i \). Therefore at most one of these terms in the left-hand side can be 1 and the other terms are zero. Combined with (5.15) this implies \( \dim(F^\bullet_2/F^\bullet_2) = \dim(F^\bullet_3/F^\bullet_3) = 0 \) for any \( i \). Thus we get a contradiction \( X^1 = X^2 = X^3 \).

If we have another submodule \( S' \) with the same property, the \((\zeta, n)\)-stability implies \( S \cap S' = 0 \) or \( S \cap S' = S = S' \). In the former case we have \( S' = X/S \). □

LEMMA 5.16 ([14, LEMMA 4.3.9])
Let \((\zeta, n)\) be as in Lemma 5.14. If \((X, F^\bullet)\) is \((\zeta, n)\)-semistable, its stabilizer is either trivial or \( C^\ast \). In the latter case, \((X, F^\bullet)\) has the unique decomposition \((X_\flat, F^\bullet_\flat) \oplus (X_\sharp, F^\bullet_\sharp)\) such that both \((X_\flat, F^\bullet_\flat)\), \((X_\sharp, F^\bullet_\sharp)\) are \((\zeta, n)\)-stable, and \( \mu_{(\zeta, n)}(X_\flat) = \mu_{(\zeta, n)}(X_\sharp) \). The stabilizer comes from that of the factor \((X_\sharp, F^\bullet_\sharp)\) with \((X_\sharp)_\infty = 0 \).
Proof
Suppose that $g$ stabilizes $(X, F^*)$. If $g$ has an eigenvalue $\lambda \neq 1$, then we have the generalized eigenspace decomposition $(X, F^*) = (X_0, F^*_0) \oplus (X_1, F^*_1)$ with $(X_0)_{\infty} = \mathbb{C}, (X_1)_{\infty} = 0$. By Lemma 5.14, $(X_0, F^*_0), (X_1, F^*_1)$ are $(\zeta, n)$-stable. Since they have the same $\mu_{\zeta, n}$ and are not isomorphic, there are no nonzero homomorphisms between them. Therefore the stabilizer is $\mathbb{C}^*$ in this case. The uniqueness follows from that in Lemma 5.14.

Next, suppose that $g$ is unipotent, and let $n = g - 1$. Assume $n \neq 0$, and let $j$ be such that $n^j \neq 0, n^{j+1} = 0$. We consider the submodule $0 \neq \operatorname{Ker} n^j \subseteq X$. From the $(\zeta, n)$-semistability of $(X, F^*)$, we have $\mu_{\zeta, n}(\operatorname{Ker} n^j, F^* \cap (\operatorname{Ker} n^j)_1) = \mu_{\zeta, n}(X, F^*)$. Therefore $(\operatorname{Ker} n^j, F^* \cap (\operatorname{Ker} n^j)_1)$ and $(X/\operatorname{Ker} n^j, F^*/F^* \cap (\operatorname{Ker} n^j)_1)$ are $(\zeta, n)$-stable by Lemma 5.14. They are not isomorphic since they have different $\infty$-components. However, $n^j : X/\operatorname{Ker} n^j \to \operatorname{Ker} n^j$ is a nonzero homomorphism, and we have a contradiction by Lemma 5.4. □

5.6. Enhanced master space
We continue to fix $c, m \in \mathbb{Z}_{\geq 0}, \ell \in N$. As we mentioned above, $\tilde{M}^m$ is constructed as a GIT quotient of a common space $\bar{Q}$ independent of $m$. Then the moduli schemes $\tilde{M}^{m,0}$ and $\tilde{M}^{m,\ell}$ will be also constructed as GIT quotients of $\bar{Q} = Q \times \operatorname{Flag}(V_1, N)$ by the action of the group $G$ with respect to a common polarization, but with different lifts of the action. Here $V_1$ is a vector space of dimension $N$, on which $G$ acts naturally, and $\operatorname{Flag}(V_1, N)$ is the variety of full flags in $V_1$. Let us denote by $L_-$ and $L_+$ the corresponding equivariant line bundles over $\bar{Q}$ to define $\tilde{M}^{m,0}$ and $\tilde{M}^{m,\ell}$, respectively. Their descents are denoted by the same notation.

We consider the projective bundle $\mathbb{P}(L_- \oplus L_+) \to \bar{Q}$ with the canonical polarization $\mathcal{O}_{\bar{Q}}(1)$. Here $\mathbb{P}(L_- \oplus L_+)$ is the space of 1-dimensional quotients of $L_- \oplus L_+$. We have the natural lifts of the $G$-action to $\mathbb{P}(L_- \oplus L_+)$ and $\mathcal{O}_{\bar{Q}}(1)$. Let

\begin{equation}
\mathcal{M} = \mathcal{M}(c) : = \mathcal{M}^{m,\ell}(c) : = \mathbb{P}(L_- \oplus L_+)^{ss}/G
\end{equation}

be the quotient stack of $\mathcal{O}_{\bar{Q}}(1)$-semistable objects of $\mathbb{P}(L_- \oplus L_+)$ divided by $G$, where $\mathbb{P}(L_- \oplus L_+)^{ss}$ denotes the semistable locus. This is called the enhanced master space. This space was introduced in [27] to study the change of GIT quotients under the change of linearizations. We have an inclusion $\mathcal{M}_a : = \mathbb{P}(L_a)^{ss}/G \to \mathcal{M}$ for $a = \pm$.

The tautological flag of vector bundles over $\operatorname{Flag}(V_1, N)$ descends to $\mathcal{M}$. We denote it by $\mathcal{F}^* = (0 = \mathcal{F}^0 \subset \mathcal{F}^1 \subset \cdots \subset \mathcal{F}^{N-1} \subset \mathcal{F}^N = V_1)$. We also have the universal sheaf $\mathcal{E}$ over $\mathbb{P}^2 \times \mathcal{M}$.

We have a natural $\mathbb{C}^*$-action on $\mathbb{P}(L_- \oplus L_+)$ given by $t \cdot [z_- : z_+] = [tz_- : z_+]$, where $[z_- : z_+]$ is the homogeneous coordinate system of $\mathbb{P}(L_- \oplus L_+)$ along fibers. It descends to a $\mathbb{C}^*$-action on $\mathcal{M}$. We have a natural $\mathbb{C}^*$-equivariant structure on the universal family $\mathcal{E}, \mathcal{F}^*$.

The following summarizes properties of $\mathcal{M}$.
Theorem 5.18

1. \( \mathcal{M} \) is a smooth Deligne-Mumford stack. There is a projective morphism \( \mathcal{M} \to M_0(p_\ast(c)) \).

2. The fixed point set of the \( \mathbb{C}^* \)-action decomposes as

\[
\mathcal{M}^{\mathbb{C}^*} = \mathcal{M}_+ \sqcup \mathcal{M}_- \sqcup \biguplus_{\mathcal{J} \in \mathcal{D}^{m,\ell}(c)} \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}),
\]

and we have isomorphisms \( \mathcal{M}_+ \cong M_{m,\ell}(c) \), \( \mathcal{M}_- \cong M_{m,0}(c) \). The universal family \( (\mathcal{E}, \mathcal{F}^\ast) \) on \( \mathcal{M} \) is restricted to ones on \( \mathcal{M}_\pm \cong M_{m,\ell}(c) \) and \( \mathcal{M}_- \cong M_{m,0}(c) \) (which were denoted by the same notation \( (\mathcal{E}, \mathcal{F}^\ast) \)). And the restriction of the \( \mathbb{C}^* \)-equivariant structure is trivial.

3. There is a diagram

\[
\begin{array}{ccc}
\mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) & \xrightarrow{F} & S(\mathcal{J}) \\
& \xleftarrow{G} & \xrightarrow{\sim} \tilde{M}_{m,\min(I)}^{-1}(c_\ast) \times \tilde{M}_{m,+}(c_\ast),
\end{array}
\]

where \( S(\mathcal{J}) \) is a smooth Deligne-Mumford stack and both \( F \) and \( G \) are étale and finite of degree \( 1/pD \). There is a line bundle \( L_S \) over \( S(\mathcal{J}) \) with \( L_S^{\otimes pD} = G^\ast(\mathcal{L}(\mathcal{E}_\ast)^\ast) \), and the restriction of the universal family \( (\mathcal{E}, \mathcal{F}^\ast) \) over \( \mathcal{M} \) and the universal families \( (\mathcal{E}_\ast, \mathcal{F}^\ast_\ast), (\mathcal{E}_\ast, \mathcal{F}^\ast_\ast) \) over \( \tilde{M}_{m,\min(I)}^{-1}(c_\ast), \tilde{M}_{m,+}(c_\ast) \) are related by

\[
F^\ast \mathcal{E} \cong G^\ast(\mathcal{E}_\ast) \oplus G^\ast(\mathcal{E}_\ast) \oplus L_S, \quad F^\ast \mathcal{F}^\ast \cong G^\ast(\mathcal{F}^\ast_\ast) \oplus G^\ast(\mathcal{F}^\ast_\ast) \otimes L_S.
\]

Moreover, the restriction of the \( \mathbb{C}^* \)-equivariant structure on the universal family \( (\mathcal{E}, \mathcal{F}) \) is trivial on the factor \( (\mathcal{E}_\ast, \mathcal{F}_\ast) \) and of weight \( 1/pD \) on \( (\mathcal{E}_\ast, \mathcal{F}_\ast) \) under the above identification.

We need to explain some notation:

- \( \mathcal{D}^{m,\ell}(c) \) is the set of decomposition types:

\[
\mathcal{D}^{m,\ell}(c) := \left\{ \mathcal{J} = (I_\ast, I_\circ) \mid \begin{array}{l}
N = I_\circ \sqcup I_\ast, \\
|I_\circ| = p(m + 1), \\
I_\circ \neq \emptyset, \\
\text{for } p \in \mathbb{Z}_{>0}, \min(I_\ast) \leq \ell
\end{array} \right\}.
\]

For \( \mathcal{J} \in \mathcal{D}^{m,\ell}(c) \), we set \( c_\ast = pe_m, \ c_\circ = c - c_\ast \in H^\ast(\overline{\mathbb{P}^2}) \).

- \( (m_0, m_1) \) appearing in the definition of an orientation of an \( (m, +) \)-stable object (see Definition 5.8) will be determined by the choice of \( L_\pm \).

The isomorphism \( \tilde{F}^\ast \mathcal{F}^\ast \cong G^\ast(\mathcal{F}^\ast_\ast) \oplus G^\ast(\mathcal{F}^\ast_\ast) \otimes L_S \) of universal flags in (3) means the following. From the first statement \( F^\ast \mathcal{E} \cong G^\ast(\mathcal{E}_\ast) \oplus G^\ast(\mathcal{E}_\ast) \otimes L_S \) we have a decomposition \( F^\ast(\mathcal{V}_1(\mathcal{E})) = G^\ast(\mathcal{V}_1(\mathcal{E}_\ast)) \oplus G^\ast(\mathcal{V}_1(\mathcal{E}_\ast)) \otimes L_S \). Then we have \( F^\ast(\mathcal{F}^\ast_\ast) = G^\ast(\mathcal{F}^\ast_\ast) \oplus G^\ast(\mathcal{F}^\ast_\ast) \otimes L_S \), where \( \mathcal{F}^\ast_\ast, \mathcal{F}^\ast_\ast \) are flags indexed by \( N \). If we forget irrelevant factors \( \mathcal{F}^\ast_\ast \) with \( \mathcal{F}^\ast_\ast = \mathcal{F}^\ast_\ast^{-1} \) and \( \mathcal{F}^\ast_\ast \) with \( \mathcal{F}^\ast_\ast = \mathcal{F}^\ast_\ast^{-1} \), we get the universal flags over \( \tilde{M}_{m,\min(I)}^{-1}(c_\circ), \tilde{M}_{m,+}(c_\ast) \). The above sets \( I_\circ, I_\ast \) consist of
indexes of relevant factors. In particular, $(\mathcal{F}^1 \subset V_1)$ appearing in Proposition 5.9 is identified with $(\mathcal{F}_{i}^{\min(I_0)} \subset \mathcal{F}_{i}^{\max(I_0)} = \mathcal{F}_{i}^{N})$. Let us denote $\mathcal{F}_{i}^{N}$ by $Y_i$ hereafter.

The fixed point substack $\mathcal{M}^{C^*}$ is defined as the zero locus of the fundamental vector field generated by the $C^*$-action. Note that this does not imply that the action of $C^*$ is trivial on $\mathcal{M}^{C^*}$ but that it becomes trivial on the finite cover $C^*_a = \text{Spec} \mathbb{C}[s, s^{-1}] \to C^*; s \mapsto st^D$. Therefore the restriction of a $C^*$-equivariant sheaf to the fixed point locus is a sheaf tensored by a $C^*_a$-module.

In the statements (2) and (3), we wrote the weights of $C^*_a$-modules divided by $pD$, considered formally as weights of rational $C^*$-modules.

The proofs of (1), (2), and (3) are given in Sections 5.7, 5.8, and 5.9, respectively.

REMARK 5.21
We can define the master space connecting $\widehat{M}^m(c)$ and $\widehat{M}^{m+1}(c)$ in the same way. However it will not necessarily be a Deligne-Mumford stack as a semistable point possibly has a stabilizer of large dimension. This is the reason why we, following Mochizuki, consider pairs of framed sheaves and flags in cohomology groups.

5.7. Smoothness of the enhanced master space
Let us write the enhanced master space in the quiver description. We first take $\zeta$ sufficiently close to $\zeta^0$. For $l = 1, \ldots, N$, we choose $(\zeta, \mathbf{n})$ satisfying (5.5) and (5.13). We take $\zeta$ so that $|\zeta - \zeta^0|, |\mathbf{n}|$ are sufficiently smaller than $|\zeta - \zeta^-|$. We take a large number $k$ so that $k(\zeta^-, \mathbf{n})$ and $k(\zeta, \mathbf{n})$ are integral. Let $L_-$ (resp., $L_+$) be the $G$-equivariant line bundle over $\mu_1(0) \times \text{Flag}(V_1, N)$ corresponding to the stability condition $k(\zeta^-, \mathbf{n})$ (resp., $k(\zeta, \mathbf{n})$). We consider the projective bundle $\mathbb{P}(L_- \oplus L_+)$ with the canonical polarization $\mathcal{O}_{\mathbb{P}}(1)$. We have the natural lifts of the $G$-action to $\mathbb{P}(L_- \oplus L_+)$ and $\mathcal{O}_{\mathbb{P}}(1)$. Let

$$\mathcal{M} := \mathcal{M}(c) := \mathbb{P}(L_- \oplus L_+)^{ss}/G$$

be the quotient stack of the semistable locus $\mathbb{P}(L_- \oplus L_+)^{ss}$ divided by $G$.

The following was shown in, for example, [27, Sections 3, 4].

LEMMA 5.22
A point $x$ of $\mathbb{P}(L_- \oplus L_+) \setminus (\mathbb{P}(L_- \cup \mathbb{P}(L_+))$ is semistable if and only if the corresponding $(X, F^*)$ is semistable with respect to a $\mathbb{Q}$-line bundle $L_t = L_-^{\otimes(1-t)} \otimes L_+^{\otimes t}$ for some $t \in [0, 1] \cap \mathbb{Q}$.

PROPOSITION 5.23
$\mathcal{M}$ is a smooth Deligne-Mumford stack.

Proof
Let $x$ be a semistable point in $\mathbb{P}(L_- \oplus L_+)$. Then the corresponding point $(X, F^*)$ in $\mu_1^{-1}(0) \times \text{Flag}(V_1, N)$ is $(\zeta', \mathbf{n})$-stable for some $\zeta'$ on the segment connecting $\zeta$.
and $\zeta^-$ (see Lemma 5.22). We can apply Lemma 5.16 as $\zeta'$ satisfies $(m + 1)\zeta_0 + (m + 2)\zeta_1 < 0$, $(m - 1)\zeta_0 + m\zeta_1 > 0$, and $n$ satisfies (5.13). Therefore either the stabilizer of $(X, F^\bullet)$ is trivial or $(X, F^\bullet)$ decomposes as $(X_1, F_{1}^\bullet) \oplus (X_2, F_{2}^\bullet)$. Since $(X_\sharp)_\infty = 0$, $X_\sharp \cong C^\oplus_m$ for some $p \in \mathbb{Z}_{>0}$ as explained in Definition 4.6. In this case the stabilizer is $C^*$, coming from the automorphisms of $(X_\sharp, F_{\sharp}^\bullet)$. Its action on the fiber is given by $t \cdot u = t^{p(k(m, m + 1) - (\zeta - \zeta^-))} u$ for $t \in C^*$. Therefore $x$ has only a finite stabilizer. It is also reduced as the base field is of characteristic zero. Therefore $\mathcal{M}$ is Deligne-Mumford. Since $\mathbb{P}(L_- \oplus L_+)$ is smooth, $\mathcal{M}$ is also smooth.

\[\text{We set } (m_0, m_1) := k(\zeta - \zeta^-) \text{ (and hence } D = k(m, m + 1) \cdot (\zeta - \zeta^-)), \text{ which was used in Theorem 5.18. From our choices of } \zeta, \zeta^- \text{, we have } D > 0.\]

**5.8. $C^*$-action**

We have a natural $C^*$-action on $\mathbb{P}(L_- \oplus L_+)$ given by $t \cdot [z_- : z_+] = [tz_- : z_+]$, where $[z_- : z_+]$ is the homogeneous coordinates system of $\mathbb{P}(L_- \oplus L_+)$ along fibers. It descends to a $C^*$-action on $\mathcal{M}$, as it commutes with the $G$-action. Letting $C^*$ act trivially on $V_0$, $V_1$ and the universal flag over $\text{Flag}(V_1, \mathcal{N})$, we have the $C^*$-equivariant structure on the universal family $\mathcal{E}$, $\mathcal{F}^\bullet = (0 = \mathcal{F}^0 \subset \mathcal{F}^1 \subset \cdots \subset \mathcal{F}^{N-1} \subset \mathcal{F}^N = V_1)$.

The fixed point substack $\mathcal{M}^{C^*}$ is defined as the zero locus of the fundamental vector field generated by the $C^*$-action. Note that this does not imply that the action of $C^*$ is trivial on $\mathcal{M}^{C^*}$. The action becomes trivial after a finite cover $C^* \to C^*$.

We have an inclusion $\mathcal{M}_a := \mathbb{P}(L_a)^{ss}/G \to \mathcal{M}$ for $a = \pm$. Then $\mathcal{M}_a$ is a component of the fixed point set $\mathcal{M}^{C^*}$. From the construction, $\mathcal{M}_a$ is the moduli stack of objects $(X, F^\bullet)$, which are stable with respect to $L_a$. From our choice of $(\zeta, n)$, we have $\mathcal{M}_+ \cong \widetilde{M}^{m, \ell}$ by Lemma 5.6. Since $n$ is sufficiently smaller than $|\zeta - \zeta^-|$, $(X, F^\bullet)$ is stable with respect to $L_-$ if and only if $X$ is $\zeta^-$-stable. Thus we have $\mathcal{M}_- \cong \widetilde{M}^{m, 0}$.

Next, consider a fixed point in $\mathcal{M}^{C^*}$ other than $\mathcal{M}_+ \cup \mathcal{M}_-$. Suppose that a point $x = ((X, F^\bullet), [z_- : z_+])$ in $\mathbb{P}(L_- \oplus L_+)^{ss} \setminus (\mathbb{P}(L_-) \cup \mathbb{P}(L_+))$ is mapped to a fixed point in the quotient $\mathcal{M}$. It means that the tangent vector generated by the $C^*$-action at $x$ is contained in the subspace generated by the $G$-action. In view of Lemma 5.16 this is possible only if $(X, F^\bullet)$ has a nontrivial stabilizer and hence decomposes as $(X_1, F_{1}^\bullet) \oplus (X_2, F_{2}^\bullet)$ to the direct sum of two $(\zeta', n)$-stable objects with the equal $\mu_{\zeta', n}$ for some $\zeta'$ on the segment connecting $\zeta$ and $\zeta^-$ (see Lemmas 5.22, 5.16). We number the summand so that $(X_\zeta)_\infty = C$. Therefore $(X_\zeta)_\infty = 0$, and hence $X_\zeta \cong C^\oplus_m$ for some $p \in \mathbb{Z}_{>0}$. The data $u = z_+/z_-$ correspond to an isomorphism $L(X) \cong C$.

Conversely, suppose that we have such a decomposition $(X, F^\bullet) = (X_\zeta, F_{\zeta}^\bullet) \oplus (X_\zeta, F_{\zeta}^\bullet)$. Let $V = V^p \oplus V^z$ be the corresponding decomposition of $V$. We lift
the $C^*$-action on $M$ to $\mathbb{P}(L_- \oplus L_+)^{ss}$ by

\[(5.24) \quad (X, F^\bullet)[\underline{z}_- : \underline{z}_+] \mapsto (\text{id}_{V_{\underline{1}}} \oplus t^{1/\ell} \text{id}_{V_{\underline{2}}}) \cdot ((X, F^\bullet), [\underline{z}_- : \underline{z}_+]),\]

which is well defined on the covering $C^* \to C^*; s \mapsto s^{\ell \cdot \delta} = t$, and fixes $((X, F^\bullet), [\underline{z}_- : \underline{z}_+]) = ((X, F^\bullet) \oplus (X_{\underline{2}}, F^\bullet_{\underline{2}}), [\underline{z}_- : \underline{z}_+])$. Since this $C^*$-action is equal to the original one up to the $G$-action, it is the same on the quotient $M$. Therefore the point $x = ((X, F^\bullet), [\underline{z}_- : \underline{z}_+])$ is mapped to a fixed point in $M$.

Let

\[I_\alpha := \{i \in \mathbb{N} | \dim(F^{\alpha i}/F^{\alpha i-1}) = 1\}\]

for $\alpha = 0, \neq$. Then we have the decomposition $N = I_0 \cup I$. The datum $(I_0, I)$ is called the decomposition type of the fixed point. Since $\dim(X_{\underline{1}}) = p(m + 1)$, we have $|I_\ell| = p(m + 1)$.

**Lemma 5.25 ([14, Lemma 4.4.3])**

We have $\min(I_\ell) \leq \ell$.

**Proof**

Suppose $\min(I_\ell) > \ell$. Then (5.5) implies $\mu_{\zeta, n}(X_{\underline{1}}) < \mu_{\zeta, n}(X)$ (see the proof of Lemma 5.6). On the other hand, we have $\mu_{\zeta, n}(X_{\underline{1}}) < \mu_{\zeta, n}(X)$ since $n$ is sufficiently smaller than $|\zeta - \zeta^-|$. Therefore we cannot have $\mu_{\zeta', n}(X_{\underline{1}}) = \mu_{\zeta', n}(X)$ for any $\zeta'$ on the segment connecting $\zeta$ and $\zeta^-$. This contradicts the assumption. \hfill \Box

Conversely, suppose that an object $(X, F^\bullet) = (X_{\underline{0}}, F^\bullet_{\underline{0}}) \oplus (X_{\underline{2}}, F^\bullet_{\underline{2}})$ with the decomposition type $(I_0, I_\ell)$ with $\min(I_\ell) \leq \ell$ is given. We also suppose $X_{\underline{2}} \cong C^\oplus_m$. We take a point $x$ of $\mathbb{P}(L_- \oplus L_+) \setminus (\mathbb{P}(L_-) \cup \mathbb{P}(L_+))$ from the fiber over $(X, F^\bullet)$. Since we have $\mu_{\zeta, n}(X_{\underline{2}}) > \mu_{\zeta, n}(X)$ and $\mu_{\zeta, n}(X_{\underline{2}}) < \mu_{\zeta, n}(X)$ by the same argument as in the proof of Lemma 5.25, we can find $\zeta'$ with $\mu_{\zeta', n}(X_{\underline{2}}) = \mu_{\zeta', n}(X)$. Then $x$ is semistable if and only if both $(X_{\underline{0}}, F_{\underline{0}})$ and $(X_{\underline{2}}, F_{\underline{2}})$ are $(\zeta', n)$-stable.

**Lemma 5.26 ([14, Proposition 4.4.4])**

1. $(X_{\underline{0}}, F_{\underline{0}})$ is $(\zeta', n)$-stable if and only if it is $(m, \min(I_\ell) - 1)$-stable.
2. $(X_{\underline{2}}, F_{\underline{2}})$ is $(\zeta', n)$-stable if and only if it is $(m, +)$-stable, that is, $X_{\underline{2}} \cong C^\oplus_m$, and we have $S_1 \cap F_{\underline{2}}^{\min(I_\ell)} = 0$ for any proper submodule $S \subseteq X_{\underline{2}}$ of a form $S \cong C^\oplus_q$.

Note that $\dim F_{\underline{2}}^{\min(I_\ell)} = 1$, $\dim F_{\underline{0}}^{\min(I_\ell) - 1} = \min(I_\ell) - 1$. So the definitions in Section 5.1 apply though $F_{\underline{0}}, F_{\underline{2}}$ are flags that possibly have repetitions.

**Proof**

1. Let $S \subseteq X_{\underline{0}}$ be a submodule. We need to study the stability inequalities when $\zeta^0 \cdot \text{dim}S = 0$. We first suppose $S_\infty = 0$. Then the inequality $\mu_{(\zeta', n)}(S) <
If we rephrase what we have observed in terms of sheaves, we get the following.

PROPOSITION 5.27 ([14, LEMMA 4.5.2])
\[ \mu(\zeta',n)(X_\delta) = \mu(\zeta',n)(X_\delta) \]
is equivalent to
\[ \frac{\sum_i n_i \dim(S_i \cap F_i^i)}{\operatorname{rank} S} < \frac{\sum_i n_i \dim F_i^i}{\operatorname{rank} X_\delta^i} \]
since \( \zeta' \cdot \dim S/ \operatorname{rank} S = \zeta' \cdot \dim X_\delta/ \operatorname{rank} X_\delta = (2m + 1)^{-1}(m\zeta'_0 + (m + 1)\zeta'_1) \).
Since \( n_i \) \((i \geq \min(I_\delta))\) is much smaller than \( n_{\min(I_\delta)}^{-1} \) by (5.5b), we must have \( S_i \cap F_i^{\min(I_\delta)} = 0 \) if the inequality holds. Conversely, suppose \( S_i \cap F_i^{\min(I_\delta)} = 0 \). Then \( S_i \cap F_i^{\min(I_\delta)} = 0 \). Thus the inequality holds again by (5.5b).

Next, suppose \( S_\infty = \mathbb{C} \). Then the inequality \( \mu(\zeta',n)(S) < \mu(\zeta',n)(X_\delta) = \mu(\zeta',n)(X_\delta) \) is equivalent to
\[ \frac{\sum_i n_i \dim(F_i^i/S_i \cap F_i^i)}{\operatorname{rank}(X_\delta/S)} > \frac{\sum_i n_i \dim F_i^i}{\operatorname{rank} X_\delta^i}. \]
This is equivalent to \( F_i^{\min(I_\delta)} \not\subset S_i \) by the same argument as above. Thus \( (X_\delta,F_\delta) \) is \((\zeta',n)\)-stable if and only if it is \((m,\min(I_\delta) - 1)\)-stable.

(2) First, note that \( X_\delta \) must be \( \zeta^0 \)-semistable as \( \zeta' \) is close to \( \zeta^0 \) and \( n \) is small. Then \( X_\delta \cong C_{m,p}^\oplus \), as explained in Definition 4.6. To prove the remaining part, the same argument as above works. \( \square \)

If we rephrase what we have observed in terms of sheaves, we get the following.

PROPOSITION 5.27 ([14, LEMMA 4.5.2])
\( \mathcal{M}^{C^+}(3) \) is the moduli stack of objects \(((E_\delta,\Phi,F_\delta^*),(E_\delta,F_\delta^*),\rho)\), where
\[ \cdot \ ((E_\delta,\Phi,F_\delta^*)) \text{ is } (m,\min(I_\delta) - 1)\text{-stable}, \]
\[ \cdot \ (E_\delta,F_\delta^*) \text{ is } (m,+)\text{-stable}, \]
\[ \cdot \ \rho \text{ is an isomorphism } L(E_\delta \oplus E_\delta) \cong \mathbb{C}. \]
Moreover, the restriction of the universal family \((\mathcal{E},\mathcal{F}^*)\) on \( \mathcal{M} \) decomposes as
\[ \mathcal{E} = \mathcal{M}\mathcal{E}_\delta \oplus \mathcal{M}\mathcal{E}_1, \quad \mathcal{F}^* = \mathcal{M}\mathcal{F}_\delta^* \oplus \mathcal{M}\mathcal{F}_1^*, \]
where \( \mathcal{M}\mathcal{F}_\delta^*,\mathcal{M}\mathcal{F}_1^* \) are flags \( (0 = \mathcal{M}\mathcal{F}_\delta^0 \subset \cdots \subset \mathcal{M}\mathcal{F}_\delta^N = \mathcal{V}_1(\mathcal{M}\mathcal{E}_\delta)), \ (0 = \mathcal{M}\mathcal{F}_1^0 \subset \cdots \subset \mathcal{M}\mathcal{F}_1^N = \mathcal{V}_1(\mathcal{M}\mathcal{E}_1)) \).

The restriction of the \( C^+ \)-equivariant structure on the universal family \((\mathcal{E},\mathcal{F})\) is trivial on the factor \((\mathcal{M}\mathcal{E}_\delta,\mathcal{M}\mathcal{F}_\delta)\) and of weight \( 1/pD \) on \((\mathcal{M}\mathcal{E}_1,\mathcal{M}\mathcal{F}_1)\) under the above identification.

The last assertion follows from the description of the \( C^+ \)-action at (5.24).

5.9. Decomposition into product of two moduli stacks
Let \( \hat{M} \) be the moduli stack of objects \(((E_\delta,\Phi,F_\delta^*,\rho_\delta)\), where
\[ \cdot \ ((E_\delta,\Phi,F_\delta^*)) \text{ is } (m,\min(I_\delta) - 1)\text{-stable}, \]
\[ \cdot \ \rho_\delta \text{ is an isomorphism } L(E_\delta) \cong \mathbb{C}. \]
We have a natural projection $\tilde{M} \to \tilde{M}^{m,\text{min}(I)}_{\mathbb{Z}}$ forgetting $\rho_q$. It is a principal $\mathbb{C}^*$-bundle. On the other hand, let $\tilde{M}^{m,+}$ be the moduli stack of oriented $(m,+)$-stable sheaves with flags as in Section 5.3. To distinguish from $\rho$, we denote the orientation by $\rho_q$. Then we have

$$\mathcal{M}^{C^*}(\mathfrak{I}) \cong (\tilde{M} \times \tilde{M}^{m,+})/\mathbb{C}^*,$$

where $\mathbb{C}^*$ acts by $\rho_q \mapsto t\rho_q$, $\rho_q \mapsto t^{-1}\rho_q$. Let us take a covering $C^*_s \to C^*$ $s \mapsto s^{pD} = t$. Then we have an étale and finite morphism $F: (\tilde{M} \times \tilde{M}^{m,+})/C^*_s \to \mathcal{M}^{C^*}(\mathfrak{I})$ of degree $1/pD$.

The action of $C^*_s$ on the second factor $\tilde{M}^{m,+}$ is trivial since it can be absorbed in the isomorphism $s^{-1} \text{id}: E_q \cong E_q$ as

$$E_q \quad \quad L(E_q) = \det H^1(E_q)^{\otimes m_0} \otimes \det H^1((E_q)(C))^{\otimes m_1} \xrightarrow{s^{-pD} \rho_q} \mathbb{C}$$

Therefore we have

$$(\tilde{M} \times \tilde{M}^{m,+})/C^*_s = \tilde{M}/C^*_s \times \tilde{M}^{m,+}.$$

Furthermore, we have an étale and finite morphism $G: \tilde{M}/C^*_s \to \tilde{M}/C^*$ of degree $1/pD$. But the latter is nothing but $\tilde{M}^{m,\text{min}(I)}/\mathbb{C}^*$. Hence, we have the diagram in Theorem 5.18 with $S(\mathfrak{I}) = (\tilde{M} \times \tilde{M}^{m,+})/C^*_s$.

From (5.28) the universal sheaf $E_q$ over $M^{m,+}$ is twisted by the line bundle over $\tilde{M}/C^*$ associated with the representation of $C^*$ with weight 1. It is a line bundle $L_S$ such that $L_S^{\otimes pD} = G^* E_q$. Therefore we have $F^*(\mathcal{M} E_q) = G^* (E_q) \otimes L_S$. On the other hand, we have $F^*(\mathcal{M} E_q) = G^* (E_q)$.

**5.10. Normal bundle**

Let us describe the normal bundles $\mathfrak{N}(\mathcal{M}_\pm)$ of $\mathcal{M}_\pm$ and $\mathfrak{N}(\mathcal{M}^{C^*}(\mathfrak{I}))$ of $\mathcal{M}^{C^*}(\mathfrak{I})$ in $\mathcal{M}$ in this subsection. We need to prepare several notations.

Recall first that the covering $C^*_s \to C^*$, $s \mapsto s^{pD} = t$ acts trivially on $\mathcal{M}^{C^*}(\mathfrak{I})$ (while the original $C^*$ does not). Hence the tangent space at a fixed point has a natural $C^*$-module structure. We formally consider it as a module structure of the original $C^*$ dividing weights by $pD$.

Recall also that the restriction of the universal sheaf $E$ decomposes as $\mathcal{M} E_q \oplus \mathcal{M} E_q$ over $\mathcal{M}^{C^*}(\mathfrak{I})$ (see Proposition 5.27). Let $\text{Ext}_{\mathfrak{q}_q}^n$ denote the higher derived functor of the composite functor $q_{2*} \circ \text{Hom}$. Let

$$(\mathcal{M}^2, \mathcal{M} E_q): = - \sum_{a=0}^2 (-1)^a \text{Ext}_{\mathfrak{q}_q}^n(\mathcal{M} E_q, \mathcal{M} E_q),$$

where this is a class in the equivariant $K$-group of $\mathcal{M}^{C^*}(\mathfrak{I})$. We use similar notation $\mathfrak{N}(\mathcal{M} E_q, \mathcal{M} E_q)$, exchanging the first and second factors. Later we will
also use \( \mathcal{N}(\bullet, \bullet) \), replacing \( \mathcal{M}\mathcal{E}_\pm \) by similar universal sheaves. We have already used this notation in Theorem 1.5.

Let

\[
\text{Flag}(V_1^\alpha, I_\alpha) = \{ \text{a flag } F_\alpha \text{ of } V_1^\alpha, \text{ indexed by } N, F_\alpha / F_\alpha^{-1} = 0 \text{ if and only if } i \notin I_\alpha \}
\]

for \( \alpha = \pm \). We have an embedding \( \text{Flag}(V_1^\alpha, I_\alpha) \times \text{Flag}(V_1^\beta, I_\beta) \to \text{Flag}(V_1, N) \) given by \((F_\alpha^*, F_\beta^*) \mapsto F_\alpha^* \oplus F_\beta^* \). Let \( N_0 \) denote its normal bundle. It has a natural \( \mathbb{C}^* \)-equivariant structure as \( \text{Flag}(V_1^\alpha, I_\alpha) \times \text{Flag}(V_1^\beta, I_\beta) \) is a component of \( \mathbb{C}^* \)-fixed points in \( \text{Flag}(V_1, N) \) with respect to the \( \mathbb{C}^* \)-action induced by \( \mathbb{C}^* \ni t \mapsto \text{id}_{V_1} \oplus t^{1/pD} \text{id}_{V_1} \in \text{GL}(V_1) \). More precisely, when we write

\[
N_0 = \bigoplus_{i > j} \text{Hom}(F_i^b / F_i^{i-1}, F_j^b / F_j^{j-1}) \oplus \bigoplus_{i > j} \text{Hom}(F_i^s / F_i^{i-1}, F_j^s / F_j^{j-1}),
\]

the first term has weight \( 1/pD \) and the second term has weight \( -1/pD \). We have an associated vector bundle, denoted also by \( N_0 \), over \( \mathcal{M}^{\mathbb{C}^*} (\mathcal{J}) \), induced from the flag bundle structure \( \overline{Q/G} \to Q/G \) between quotient stacks.

**Theorem 5.30**

1. The normal bundle \( \mathcal{N}(\mathcal{M}_\pm) \) of \( \mathcal{M}_\pm \) is \( \mathbb{L}^* \otimes \mathbb{L}_\pm \) with the \( \mathbb{C}^* \)-action of weight \( \pm 1 \).

2. The normal bundle \( \mathcal{N}(\mathcal{M}^{\mathbb{C}^*}(\mathcal{J})) \) of \( \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) \) is equivariant K-theoretically given by

\[
N_0 + \mathcal{N}(\mathcal{M}_\pm, \mathcal{M}_\pm) \otimes I_1/pD + \mathcal{N}(\mathcal{M}_+, \mathcal{M}_+) \otimes I_{-1/pD},
\]

where \( I_n \) denotes the trivial line bundle over \( \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) \) with the \( \mathbb{C}^* \)-action of weight \( n \).

**Proof**

First, consider the case \( \mathcal{M}_\pm = \mathbb{P}(\mathbb{L}_\pm)^{ss} / G \). The normal bundle is the descent of the normal bundle \( \mathbb{P}(\mathbb{L}_\pm) \subset \mathbb{P}(\mathbb{L}_- \oplus \mathbb{L}_+) \). Then it is \( \mathbb{L}^* \otimes \mathbb{L}_\pm \) with the \( \mathbb{C}^* \)-action of weight \( \pm 1 \).

In the remainder of the proof we consider the case of \( \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) \). The normal bundle is the sum of nonzero weight subspaces in the restriction of the tangent bundle of \( \mathcal{M} \) to \( \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) \).

Take a point \(( (X, F^*), [z_- : z_+] ) \in \mathbb{P}(\mathbb{L}_- \oplus \mathbb{L}_+)^{ss} \) which descends to a fixed point in \( \mathcal{M}^{\mathbb{C}^*}(\mathcal{J}) \). We have a decomposition \((X, F^*) = (X_b, F_b^*) \oplus (X_s, F_s^*) \) as above. Let \( V = V^b \oplus V^s \) be the corresponding decomposition of \( V \).

We lift the \( \mathbb{C}^* \)-action on \( \mathcal{M} \) to \( \mathbb{P}(\mathbb{L}_- \oplus \mathbb{L}_+)^{ss} \) as in (5.24).

The tangent space at the point corresponding to \(( (X, F^*), [z_- : z_+] ) \) is the quotient vector space

\[
\text{Ker} \, d\mu \oplus T_{F^*} \text{Flag}(V_1, N) \oplus T_{[z_- : z_+]} \mathbb{P}^1 / \text{Hom}(V_0, V_0) \oplus \text{Hom}(V_1, V_1),
\]
where \(d\mu\) and \(\text{Hom}(V_0, V_0) \oplus \text{Hom}(V_1, V_1) \to \text{Ker} \, d\mu\) are as in (4.4), and \(\text{Hom}(V_0, V_0) \oplus \text{Hom}(V_1, V_1) \to T_{F^*} \cdot \text{Flag}(V, N) \oplus T_{\mathbb{P}^1}^{[z:z_0]}\) is the differential of the \(G\)-action. This quotient space has the \(\mathbb{C}^*\)-module structure induced from the above lift of the \(\mathbb{C}^*\)-action.

In the equivariant \(K\)-group, we can replace this space with \(\text{Ker} \, d\mu - (\text{Hom}(V_0, V_0) \oplus \text{Hom}(V_1, V_1)) + T_{F^*} \cdot \text{Flag}(V, N) + T_{\mathbb{P}^1}^{[z:z_0]}\).

The expression \(\text{Ker} \, d\mu - (\text{Hom}(V_0, V_0) \oplus \text{Hom}(V_1, V_1))\) is equal to the alternating sum of cohomology groups of the tangent complex (4.4) in the \(K\)-group. Moreover, the complex (4.4) decomposes into four parts: the tangent complex for \(X_3\), the sum of \(p\)-copies of the complex (4.8) for \(X_3\), the sum of \(p\)-copies of the complex (4.10) for \(X_3\), and the sum of \(p^2\)-copies of the tangent complex for \(C_m\). Since \(\mathbb{C}^*\) acts on \(V^p\) with weight zero and \(V^1\) with weight 1, the first and fourth parts do not contribute to the normal bundle. The second and third terms give

\[
\begin{align*}
&- \text{Ext}_p^0(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) + \text{Ext}_p^1(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) \otimes I_{1/pD} \\
+ &\left( - \text{Ext}_p^0(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) + \text{Ext}_p^1(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) \right) \otimes I_{1/pD} \\
= &\mathcal{H}(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) \otimes I_{1/pD} + \mathcal{H}(\mathcal{M} \mathcal{E}_0, \mathcal{M} \mathcal{E}_1) \otimes I_{1/pD}.
\end{align*}
\]

The contribution from \(T_{F^*} \cdot \text{Flag}(V, N)\) is given by \(N_0\). Thus we have Theorem 5.30. We have no contribution from \(T_{\mathbb{P}^1}^{[z:z_0]}\).

\[\square\]

### 5.11. Relative tangent bundles of flag bundles

Let \(\Theta_{\text{rel}}\) be the bundles over various moduli stacks induced from the relative tangent bundle of the flag bundle \(\tilde{Q}/G \to Q/G\) as in Section 6.2.

On the other hand, we have vector bundles \(\Theta^p_{\text{rel}}, \Theta^q_{\text{rel}}\) over \(\tilde{M}^{m, \min(I_1)}(c_0) \times \tilde{M}^{m, +}(c_1)\) coming from the tangent bundles of \(\text{Flag}(V_1^p, I_1)\) and \(\text{Flag}(V_1^q, I_2)\). Recall that the normal bundle \(N_0\) of \(\text{Flag}(V_1^p, I_1) \times \text{Flag}(V_1^q, I_2)\) in \(\text{Flag}(V, N)\) is considered a vector bundle over \(\tilde{M}^{m, \min(I_1)}(c_0) \times \tilde{M}^{m, +}(c_1)\) (see Section 5.10), so we have an exact sequence

\[
(5.31) \quad 0 \to G^* (\Theta^p_{\text{rel}} \oplus \Theta^q_{\text{rel}}) \to F^* \Theta_{\text{rel}}|_{\mathcal{M}^{\mathbb{C}^*}} \to G^* (N_0) \to 0
\]

of \(\mathbb{C}^*\)-equivariant vector bundles, where \(\Theta^p_{\text{rel}} \oplus \Theta^q_{\text{rel}}\) has weight 0 and \(N_0\) has the \(\mathbb{C}^*\)-equivariant structure as describe in Section 5.10.

Recall also that the second factor \(\tilde{M}^{m, +}(c_1)\) is the flag bundle \(\text{Flag}(V_1^q/\mathcal{F}_q^{\min(I_2)}, I_2 \setminus \{\min(I_2)\})\) over the quotient stack \((\det Q^{\otimes D})^\times/\mathbb{C}^*\) (see Proposition 5.9). Let \(\Theta^q_{\text{rel}}\) be the relative tangent bundle of the fiber. Then we have an exact sequence of vector bundles

\[
(5.32) \quad 0 \to \Theta^q_{\text{rel}} \to \Theta^q_{\text{rel}} \to \text{Hom}(V_1^q/\mathcal{F}_q^{\min(I_2)}, \mathcal{F}_q^{\min(I_1)}) \to 0
\]

coming from the fibration \(\text{Flag}(V_1^q/\mathcal{F}_q^{\min(I_2)}) \to \text{Flag}(V_1^q) \to \mathbb{P}(V_1^q)\).
6. Wall-crossing formula

We now turn to Mochizuki method (Mb) (see [14, Section 7.2]). We apply
the fixed point formula to the equivariant homology groups $H^T \times C^* (\mathcal{M}(c))$ of
the enhanced moduli space $\mathcal{M}(c)$, which is a module over $H^*_\mathbb{C}(pt) \cong \mathbb{C}[h]$. For
the definition of the homology group of a Deligne-Mumford stack, see [28].

6.1. Equivariant Euler class

In the fixed point formula, we put an equivariant Euler class in the denominator
and we later consider an equivariant Euler class of a class in the $K$-group. Let
us explain how we treat them in this subsection.

Let $Y$ be a variety (or a Deligne-Mumford stack) with a trivial $\mathbb{C}^*$-action.
The Grothendieck group of $\mathbb{C}^*$-equivariant vector bundles decomposes as
$K_{\mathbb{C}^*}(Y) = K(Y) \otimes_\mathbb{R} R(\mathbb{C}^*)$, where $R(\mathbb{C}^*)$ is the representation ring of $\mathbb{C}^*$. Let
$I_n$ denote the 1-dimensional representation of $\mathbb{C}^*$ with weight $n$. For a class $\alpha \in
K(Y)$, we set

$$e(\alpha \otimes I_n) := \sum_{i \geq 0} c_i(\alpha)(nh)^{r(\alpha) - i} \in H^*(Y)[h^{-1}, h] := H^*(Y) \otimes_\mathbb{C} \mathbb{C}[h^{-1}, h],$$

where $c_i(\alpha)$ is the $i$th Chern class of $\alpha$ and $r(\alpha) = \text{ch}_0(\alpha)$ is the (virtual) rank
of $\alpha$. If $n \neq 0$, this element is invertible. In general, if $\alpha \in K_{\mathbb{C}^*}(Y)$ is a sum of
$\alpha_n \otimes I_n$ with $n \neq 0$, its equivariant Euler class $e(\alpha)$ is defined in $H^*(Y)[h^{-1}, h]$.

We also consider the case when another group $\tilde{T}$ acts on $Y$. Then $e(\alpha \otimes I_n)$
can be still defined as an element in $\lim_n H^*(Y \times _{\tilde{T}} E_n)[h^{-1}, h]$, where $E_n \to E_n/\tilde{T}$
is a finite-dimensional approximation of the classifying space $ET \to B\tilde{T}$ for $\tilde{T}$.
Note that $c_i(\alpha) \neq 0$ for possibly infinite $i$'s.

6.2. Wall-crossing formula (I)

The projective morphism $\tilde{\pi}: \mathcal{M}(c) \to M_0(p_*(c))$ induce a homomorphism $\tilde{\pi}_*: H^T \times C^* (\mathcal{M}(c)) \to H^T \times C^* (M_0(p_*(c)))$. Since $\mathbb{C}^*$ acts trivially on $M_0(p_*(c))$, we
have $H^T \times C^* (M_0(p_*(c))) \cong H^T (M_0(p_*(c))) \otimes \mathbb{C}[h]$. For a cohomology class $\bullet$ on
$\mathcal{M}(c)$, we denote the pushforward $\tilde{\pi}_*(\bullet \cap [\mathcal{M}(c)])$ by $\int_{\mathcal{M}(c)} \bullet$ as in Section 1. We
also use similar pushforward homomorphisms from homology groups of various
moduli stacks and denote them in similar ways, for example, $\int_{\mathcal{M}_+}(\cdot), \int_{\mathcal{M}_-^c}(\cdot)$.

Let $e(\mathcal{F})$ denote the equivariant Euler class of the equivariant vector bundle $\mathcal{F}$, that is, the top Chern class $c_{\text{top}}(\mathcal{F})$ (see Section 6.1 for its generalization to a $K$-theory class $\mathcal{F}$ in our situation).

Let $\Phi(\mathcal{E})$ be as in Section 1.4. We denote also by $\Phi(\mathcal{E})$ the class on $\tilde{M}^{m, \ell}(c)$
given by the same formula. On the enhanced master space $\mathcal{M}(c)$, we can con-
sider the class defined by the same formula as $\Phi(\mathcal{E})$, which is regarded as a $\mathbb{C}^*$-equivariant
class.

Let $\Theta_{\text{rel}}$ be the relative tangent bundle of the flag bundle $\tilde{Q}/G \to Q/G$. Then
we have the induced bundle over $\tilde{M}^{m, \ell}(c)$ by the restriction. We denote it also
by $\Theta_{\text{rel}}$ for brevity. We also have the pullback to the enhanced master space.
\( \mathcal{M}(c) \), which is again denoted by \( \Theta_{\text{rel}} \). It has a natural \( \mathbb{C}^* \)-equivariant structure.

We introduce \( \tilde{\Phi}(E) := \frac{1}{v_1(c)!} \Phi(E) \cup e(\Theta_{\text{rel}}) \), so that we have

\[
\int_{\tilde{M}^{m,0}(c)} \tilde{\Phi}(E) = \int_{\tilde{M}^{m}(c)} \Phi(E).
\]

Here \( v_1(c) = \dim V_1(E) \) for a sheaf \( E \) with \( \text{ch}(E) = c \).

Then the fixed point formula in the equivariant homology group gives us

\[
\int_{\hat{M}^{m}(c)} \Phi(E) \quad \text{and} \quad \int_{\tilde{M}^{m,\ell}(c)} \tilde{\Phi}(E) = \sum_{I \in \mathcal{D}^{m,\ell}(c)} \text{Res}_{h=0} \left[ \frac{\tilde{\Phi}(E) \oplus (C_m \otimes Q \otimes I_1)}{\mathfrak{R}(\mathcal{M}^{C*}(\mathcal{I}^m))} \right],
\]

where \( \text{Res}_{h=0} \) means taking the coefficient of \( h^{-1} \).

By Proposition 5.9 and Theorem 5.18 together with computations of normal bundles (see Section 5.10), we can rewrite the right-hand side to get the following theorem.

**Theorem 6.1**

We have

\[
\int_{\hat{M}^{m}(c)} \Phi(E) - \int_{\tilde{M}^{m,\ell}(c)} \tilde{\Phi}(E) = \sum_{I \in \mathcal{D}^{m,\ell}(c)} \text{Res}_{h=0} \left[ \tilde{\Phi}(I_0 \oplus (C_m \otimes Q \otimes I_1)) \Phi'(E_0) \right],
\]

where \( \Phi'(E_0) = \frac{(v_1(c_0) - 1)!v_1(c_2)!}{v_1(c)!} \)

\[
\times \int_{\text{Gr}(m+1,p)} e(\mathfrak{R}(E_0, C_m) \otimes Q \otimes I_{-1}) e(\mathfrak{R}(C_m, E_0) \otimes Q^* \otimes I_1).
\]

Here \( I_n \) denotes the trivial line bundle with the \( \mathbb{C}^* \)-action of weight \( n \), and \( \mathfrak{R}(\bullet, \bullet) \) is the equivariant \( K \)-theory class given by the negative of the alternating sum of \( \text{Ext} \)-groups (see (5.29); note that \( \Phi' \) depends on \( \mathcal{I} \)).

The proof is given in Section 6.3.

**6.3. Fixed point formula on the enhanced master space**

Let \( \iota_+, \iota_0 \) be the inclusions of \( \mathcal{M}^{\pm}(c), \mathcal{M}^{C*}(\mathcal{I}) \) into \( \mathcal{M}(c) \). Let \( \iota_+, \iota_0 \) be the pullback homomorphisms, which are defined as \( \mathcal{M}(c) \) is smooth. They will be omitted from formulas eventually. Let \( e(\mathfrak{R}(\mathcal{M}_+(c))) \), \( e(\mathfrak{R}(\mathcal{M}^{C*}(\mathcal{I}))) \) be the equivariant Euler class of the normal bundles \( \mathfrak{R}(\mathcal{M}_+(c)), \mathfrak{R}(\mathcal{M}^{C*}(\mathcal{I})) \). The localization theorem in the equivariant cohomology groups says that the following
The diagram is commutative:

\[
\lim_n H^*_n (\mathcal{M}(c) \times \mathcal{E} E_n) \otimes \mathbb{C}[h] \mathbb{C}[h^{-1}, h] \xrightarrow{\cong} \lim_n H_* (\mathcal{M}(c)^* \times \mathcal{E} E_n)[h^{-1}, h]
\]

\[
\lim_n H_* (\mathcal{M}_0(p^*(c) \times \mathcal{E} E_n))[h^{-1}, h] \quad \text{where the upper horizontal arrow is given by}
\]

\[
\frac{\lambda_n^*}{e(\mathcal{N}(\mathcal{M}_+(c)))} + \frac{\lambda_n^*}{e(\mathcal{N}(\mathcal{M}_-(c)))} + \sum_3 e(\mathcal{N}(\mathcal{M}^*(3)))
\]

and \( E_n \to E_n/\mathcal{T} \) is a finite-dimensional approximation of \( E\mathcal{T} \to B\mathcal{T} \) as above.

Let \( \mathcal{T}(1) \) be the trivial line bundle with \( \mathbb{C}^* \)-action of weight 1. We have

\[
\int_{\mathcal{M}(c)} \bar{T}(c_1)(\mathcal{T}(1)) = \sum_{a=\pm} \int_{\mathcal{M}_a(c)} \bar{T}(c_1)(\mathcal{T}(1)) \frac{1}{e(\mathcal{N}(\mathcal{M}_a))}
\]

\[
+ \sum_{\gamma \in \mathcal{D}^{m,c}(3)} \int_{\mathcal{M}^*(3)} \bar{T}(c_1)(\mathcal{T}(1)) \frac{1}{e(\mathcal{N}(\mathcal{M}^*(3)))}
\]

in \( \lim_n H_* (\mathcal{M}_0(p^*(c) \times \mathcal{E} E_n))[h^{-1}, h] \). Since \( \mathcal{T}(1) \) is a trivial line bundle if we forget the \( \mathbb{C}^* \)-action, the left-hand side is restricted to zero at \( h = 0 \):

\[
\int_{\mathcal{M}(c)} \bar{T}(c_1)(\mathcal{T}(1))|_{h=0} = 0.
\]

On the other hand, \( c_1(\mathcal{T}(1))|_{\mathcal{M}_a(c)} = h \) and \( c_1(\mathcal{T}(1))|_{\mathcal{M}^*(3)} = h \). Moreover, we have

\[
\frac{1}{e(\mathcal{N}(\mathcal{M}_a))} = a(h - \omega)^{-1} = \frac{a}{h} \sum_{i=0}^{\infty} \left( \frac{\omega}{h} \right)^i
\]

for \( a = \pm \), where \( \omega = c_1(L^*_+ \otimes L_-) \). Combining with Theorem 5.18(2), we get

\[
(6.3)
\]

\[
\int_{\mathcal{M}^*(3)} \bar{T}(\mathcal{E}) - \int_{\mathcal{M}^*(c)} \bar{T}(\mathcal{E}) = - \sum_{\gamma \in \mathcal{D}^{m,c}(3)} \text{Res}_{h=0} \int_{\mathcal{M}^*(3)} \frac{\bar{T}(\mathcal{E})}{e(\mathcal{N}(\mathcal{M}^*(3)))}.
\]

We now use the diagram (5.19) to rewrite the integral in the right-hand side of (6.3):

\[
\int_{\mathcal{M}^*(3)} \frac{\bar{T}(\mathcal{E})}{e(\mathcal{N}(\mathcal{M}^*(3)))} = pD \int_{\mathcal{S}(3)} \frac{F^* \bar{T}(\mathcal{E})}{e(\mathcal{N}(\mathcal{M}^*(3)))}.
\]

From Theorem 5.18(3) we have

\[
F^* (\bar{T}(\mathcal{E})) = \Phi (G^*(\mathcal{E}_b) \oplus G^*(\mathcal{E}_t) \otimes L_\mathcal{S} \otimes I_{1/pD}).
\]
Since $L_{S}^{\otimes pD} = G^*(\mathcal{L}(E_\delta)^*)$, we have
\[
c_1(L_S) = -\frac{1}{pD}G^*c_1(\mathcal{L}(E_\delta)).
\]
Since $L_S$ appears as $c_1(L_S)$ in $\Phi(G^*(E_\delta) \otimes L_S \otimes I_{1/pD})$, we can formally write
\[
\Phi(G^*(E_\delta) \otimes G^*(E_\delta) \otimes L_S \otimes I_{1/pD}) = G^*\Phi(E_\delta \otimes E_\delta \otimes \mathcal{L}(E_\delta)^{-1/pD} \otimes I_{1/pD}),
\]
meaning that we replace $c_1(L(S))$ with $c_1(L(S))/pD$.

Similarly from Theorems 5.30 and 5.18(3) we have
\[
\int_{\mathcal{M}}^{\mathcal{M}^+} F^*(\mathcal{M}(\mathcal{M}^+)) = F^*(e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+)) = G^*(e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+) \mathcal{M}^+) = G^*e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+) e(N_0).
\]

From (5.31) and (5.32) we have
\[
F^*(e(\Theta_{\text{rel}})) = G^*e(\Theta_{\text{rel}} e(\Theta_{\text{rel}}) e(N_0)) = G^*e(\Theta_{\text{rel}} e(\Theta_{\text{rel}}) e(\text{Hom}(\mathcal{M}^+/\mathcal{I}^{\min(I_1)}, \mathcal{I}^{\min(I_1)}))) e(N_0).
\]

Therefore we get
\[
pD \int_{S(3)} F^*\Phi = \frac{1}{v_1(c)!} \int_{M^{m, \min(I_1)-1}} \Phi(\mathcal{M} \mathcal{M}^+) e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+ \mathcal{M}^+) e(N_0) e(N_0) e(\text{Hom}(\mathcal{M}^+/\mathcal{I}^{\min(I_1)}, \mathcal{I}^{\min(I_1)})) \frac{e(\Theta_{\text{rel}} e(\Theta_{\text{rel}}) e(\text{Hom}(\mathcal{M}^+/\mathcal{I}^{\min(I_1)}, \mathcal{I}^{\min(I_1)})))}{e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+) e(N_0)}.
\]

We use the claim that $\tilde{M}^{m, +}(c_\delta)$ is a flag bundle over $(\det Q^{\otimes D}) / \mathbb{C}^*$ (see Proposition 5.9(1)) to rewrite this further as
\[
\frac{(v_1(c_\delta) - 1)!}{v_1(c)!} \int_{\tilde{M}^{m, \min(I_1)-1}} \Phi(\mathcal{M} \mathcal{M}^+) e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+ \mathcal{M}^+) e(N_0) e(\text{Hom}(\mathcal{M}^+/\mathcal{I}^{\min(I_1)}, \mathcal{I}^{\min(I_1)})) \frac{e(\Theta_{\text{rel}} e(\Theta_{\text{rel}}) e(\text{Hom}(\mathcal{M}^+/\mathcal{I}^{\min(I_1)}, \mathcal{I}^{\min(I_1)})))}{e(\mathcal{M}(\mathcal{M}^+) \mathcal{M}^+) e(N_0)}.
\]

We set $\Phi(\bullet) := 1/(v_1(c_\delta)!)\Phi(\bullet) e(\Theta_{\text{rel}})$, use Proposition 5.9(2) to replace $(\det Q^{\otimes D}) / \mathbb{C}^*$ by $\text{Gr}(m + 1, p)$, and then plug into (6.3) to get
Therefore we have
\[ \Phi(E) = \int_{\tilde{M}^{m,t}(c)} \Phi(E) - \int_{\tilde{M}^{m}(c)} \Phi(E) = \sum_{s \in D^{m,t}(c)} \int_{\tilde{M}^{m,\min(t_s)}^{-1}(c_s)} \Res \tilde{\Phi}(E_s) \oplus E_{\mathbb{A}} \otimes L(E_s)^{-1/pD} \otimes I_{1/pD} \Phi'(E_s), \]

where
\[ \Phi'(E_s) = -\frac{(v_1(c_s) - 1)!v_1(c_s)!}{v_1(c_s)!|pD|} \int_{Gr(m+1,p)} \varnothing, \]
\[ \varnothing = e(M(E_s,C_m) \otimes \mathcal{O} \otimes \det Q^{-1/p} \otimes L(E_s)^{-1/pD} \otimes I_{1/pD}) \]
\[ \times e(M(C_m,E_s) \otimes \mathcal{O}^* \otimes \det Q^1/p \otimes L(E_s)^{1/pD} \otimes I_{-1/pD}). \]

Here
\[ \cdot \int_{Gr(m+1,p)} \text{ means the pushforward with respect to the projection } \]
\[ \tilde{M}^{m,\min(t_s)}^{-1}(c_s) \times Gr(m+1,p) \to \tilde{M}^{m,\min(t_s)}^{-1}(c_s); \]
\[ \cdot \text{ det } Q^{-1/p} \text{ is understood as before: we replace } c_1(\det Q^{-1/p}) \text{ with } -c_1(\det Q)/p. \]

Let us slightly simplify the formula. First note that \( I_{\pm 1/pD} \) appears with \( \det Q^{1/p} \otimes L(E_s)^{1/pD} \). Let \( \omega = -\left(c_1(L(E_s)) + c_1(Q)\right)/pD \). Thus \( \Phi'(E_s) \) is written as
\[ \sum_{j=-\infty}^{\infty} A_j(h - \omega)^j. \]

By a direct calculation, we have
\[ \Res_{h=0}(h - \omega)^j = \begin{cases} 1 & \text{if } j = -1, \\ 0 & \text{otherwise.} \end{cases} \]

Therefore we have
\[ \Res_{h=0} \sum_{j=-\infty}^{\infty} A_j(h - \omega)^j = \Res_{h=0} \sum_{j=-\infty}^{\infty} A_jh^j. \]

This means that we can erase \( \det Q^{1/p} \otimes L(E_s)^{1/pD} \) from \( \Phi'(E_s) \). (The last simplification appeared in [14, proof of Theorem 7.2.4].)

Next, note that nontrivial contributions of the \( \mathbb{C}^* \)-action appear as \( I_{\pm 1/pD} \).

If we take the covering \( \mathbb{C}^*_s \to \mathbb{C}^*, \ s \mapsto t = s^{-pD}, \ I_{\pm 1/pD} \) is of weight \( \mp 1 \) as a \( \mathbb{C}^*_s \)-module by our convention. Since we have a natural isomorphism \( H^*_{\mathbb{C}^*_s}(pt) = \mathbb{C}[h_s] \cong H^*_{\mathbb{C}^*}(pt) = \mathbb{C}[h] \) by \( h_s = -h/pD \), we can replace \( h \) by \( h_s \), noticing \( \Res_{h=0} f(h) = -pD \times \Res_{h=0} f(h_pD). \) We use this replacement and then replace \( h_s \) by \( h \) again. Therefore we get formula (6.2). We have completed the proof of Theorem 6.1. \qed
6.4. Proof of Theorem 1.5

The right-hand side of the formula in Theorem 6.1 can be expressed by an integral over \( \hat{M}^m(c) \) by using the formula again. We continue this procedure recursively; we get a wall-crossing formula comparing \( \int_{\hat{M}^m(c)} \) and \( \int_{\hat{M}^{m+1}(c)} \). We then get Theorem 1.5. The proof has combinatorial nature and is the same as one in [14, Section 7.6]. We reproduce it here for the reader’s convenience.

In fact, it is enough to consider the case \( m = 0 \), as a general case follows from \( m = 0 \) since we have an isomorphism \( \hat{M}^m(c) \cong \hat{M}^0(c \circ m[C]) \). (\( E, \Phi \rightarrow (E(-mC), \Phi) \). Then the formula in Theorem 6.1 is simplified as we can assume \( p = 1 \) as \( \text{Gr}(m + 1, p) = \text{Gr}(1, p) \) is empty otherwise. Theorem 1.5 is obtained in this way, but we give a proof for general \( m \).

For \( j \in \mathbb{Z}_{>0} \), let

\[
S^m_j(c) := \{ \vec{c} = (c_0, p_1, \ldots, p_j) \in H^*(\mathbb{P}^2) \times \mathbb{Z}^j \mid (c_0, [\ell_\infty]) = 0, c_0 + \sum_{i=1}^j p_i e_m = c \}. 
\]

We denote the universal family for \( \hat{M}^m(c) \) by \( E \), as above. Let \( S^m_j(c) = \cup_{j=1}^\infty S^m_j(c) \).

For \( \vec{p} = (p_1, \ldots, p_j) \in \mathbb{Z}^j \) we consider the product of Grassmannian varieties \( \prod_{i=1}^j \text{Gr}(m + 1, p_i) \). Let \( Q^{(i)} \) be the universal quotient of the \( i \)th factor. We consider the \( j \)-dimensional torus \( (\mathbb{C}^*)^j \) acting trivially on \( \prod_{i=1}^j \text{Gr}(m + 1, p_i) \).

We denote the 1-dimensional weight \( n \) representation of the \( i \)th factor by \( e^{nh_i} \), (denoted by \( I_n \) previously). The equivariant cohomology \( H^*_{(\mathbb{C}^*)^j}(\text{pt}) \) of the point is identified with \( \mathbb{C}[h_1, \ldots, h_j] \).

**THEOREM 6.4**

We have

\[
\int_{\hat{M}^{m+1}(c)} \Phi(E) - \int_{\hat{M}^m(c)} \Phi(E) = \sum_{\vec{c} \in S^m_j(c)} \text{Res} \cdots \text{Res} \Phi\left( E \oplus \bigoplus_{i=1}^j C_m \boxtimes Q^{(i)} \otimes e^{-h_i} \right) \cup \Psi^\vec{p}(E), 
\]

where \( \Psi^\vec{p}(\bullet) \) is another cohomology class given by

\[
\Psi^\vec{p}(\bullet) := \frac{1}{(m + 1)^j} \prod_{i=1}^j \sum_{1 \leq k \leq i} p_k \int_{\prod_{i=1}^j \text{Gr}(m + 1, p_i)} \bigwedge,
\]

\[
\bigwedge = \prod_{i=1}^j e\left( (V_i(C_m) \otimes Q^{(i)}/O)^* \right) \times \prod_{1 \leq i_1 \neq i_2 \leq j} e\left( Q^{(i_1)} \otimes Q^{(i_2)*} \otimes e^{-h_{i_1} + h_{i_2}} \right). 
\]

(Note that \( \Psi^\vec{p} \) depends on \( \vec{p} = (p_1, \ldots, p_j) \), but not on \( c_0 \).)

Let us prepare notation before starting the proof.
We defined a cohomology class $\Psi^\delta(\mathcal{E})$ by the formula (6.5), and it is an element in $H^*_c(\mathbb{P}^2 \times \mathbb{P}^2 \times \prod_{j=1}^J \text{Gr}(m+1, p^{(j)}))[h_1^\pm, \ldots, h_j^\pm]$ for some moduli stack $M$ with the universal family $\mathcal{E}$.

Let $\text{Dec}^{(j)}(c)$ be the set of pairs $\mathcal{J}^{(j)} = (I^{(j)}_b, I^{(j)}_g)$ as follows:

- $I^{(j)}_b$ is a tuple $(I^{(j)}_b(0), I^{(j)}_b(1), \ldots, I^{(j)}_b(J))$ of subsets of $v_1(c)$ such that $|I^{(j)}_b| = p_i(m+1)$ for some $p_i \in \mathbb{Z}_{>0}$ (1 ≤ $i$ ≤ $j$);
- $\min(I^{(j)}_b(1)) > \cdots > \min(I^{(j)}_b(J))$;
- $I^{(j)}_g$ is also a subset of $v_1(c)$, and we have $v_1(c) = I^{(j)}_b \cup \bigcup_{i=1}^j I^{(j)}_g$.

For $\mathcal{J}^{(j)} \in \text{Dec}^{(j)}(c)$, set
\[
\kappa(\mathcal{J}^{(j)}) := \max\{ i \in I^{(j)}_b \mid i < \min(I^{(j)}_g) \},
\]
where we understand this to be zero if there exists no $i \in I^{(j)}_b$ with $i < \min(I^{(j)}_g)$.

We also put
\[
c^{(i)}_b := p_ie_m \quad (1 \leq i \leq j), \quad c^{(j)}_b := c - \sum_{i=1}^j p_ie_m.
\]

We have a map $\pi_j : \text{Dec}^{(j+1)}(c) \to \text{Dec}^{(j)}(c)$; $(I^{(j+1)}_b, I^{(j+1)}_g) \mapsto (I^{(j)}_b, I^{(j)}_g)$ given by
\[
I^{(j)}_b := I^{(j+1)}_b \cup I^{(j+1)}_g, \quad I^{(j)}_g := (I^{(j)}_g(1), \ldots, I^{(j)}_g(J)).
\]

Let
\[
\tilde{M}(\mathcal{J}^{(j)}) := \tilde{M}^{m, \ell}(c^{(j)}_b), \quad \tilde{M}(\mathcal{J}^{(j)}) := \tilde{M}^{m}(c^{(j)}_b),
\]
where in the first equality we take the unique order-preserving bijection $I^{(j)}_b \cong v_1(c^{(j)}_b) = \#I^{(j)}_b$ and take $\ell \in v_1(c^{(j)}_b)$ corresponding to $\kappa(\mathcal{J}^{(j)})$.

For the universal family $\mathcal{E}^{(j)}_b$ for $\tilde{M}(\mathcal{J}^{(j)})$ or $\tilde{M}(\mathcal{J}^{(j)})$, let
\[
\Psi^{\mathcal{J}^{(j)}}(\mathcal{E}^{(j)}_b) := \Psi^\delta(\mathcal{E}^{(j)}_b) \frac{v_1(c^{(j)}_b)! \prod_{i=1}^j (v_1(c^{(j)}_b) - 1)!}{v_1(c)!} \frac{(m+1)^j}{\prod_{i=1}^j \sum_{k=1} p_k},
\]
where $\vec{p} = (p_1, \ldots, p_j)$.

**LEMMA 6.6 ([14, LEMMA 7.6.5])**

For each $j$, we have the formula
\[
\int_{\tilde{M}^{m+1}(c)} \Phi(\mathcal{E}) - \int_{\tilde{M}^{m}(c)} \Phi(\mathcal{E}) = \sum_{1 \leq i < j} \int_{\tilde{M}(\mathcal{J}^{(i)})} \text{Res} \cdots \text{Res} \Phi \left( \mathcal{E}^{(i)}_b \oplus \bigoplus_{k=1}^i C_m \boxtimes Q^{(k)} \otimes e^{-h_k} \right) \times \Psi^{\mathcal{J}^{(i)}}(\mathcal{E}^{(i)}_b)
\]
(6.7)
Hiraku Nakajima and Kôta Yoshioka

\[ + \sum_{\mathcal{J}(j) \in \text{Dec}^{(j)}(c)} \int_{\tilde{M}(\mathcal{J}(j))} \text{Res} \cdots \text{Res} \tilde{\Phi} \left( \mathcal{E}_b^{(j)} \oplus \bigoplus_{k=1}^{j} C_m \boxtimes Q^{(k)} \otimes e^{-h_k} \right) \times \Psi^{\mathcal{J}(j)} (\mathcal{E}_b^{(j)}) \]

**Proof**

We prove the assertion by an induction on \( j \). If \( j = 1 \), this is nothing but Theorem 6.1 applied to \( \ell = v_1(c) \).

Suppose that the formula is true for \( j \). We apply Theorem 6.1 to get

\[
\int_{\tilde{M}(\mathcal{J}(j))} \text{Res} \cdots \text{Res} \tilde{\Phi} \left( \mathcal{E}_b^{(j)} \oplus \bigoplus_{k=1}^{j} C_m \boxtimes Q^{(k)} \otimes e^{-h_k} \right) \Psi^{\mathcal{J}(j)} (\mathcal{E}_b^{(j)})
\]

\[
- \int_{\tilde{M}(\mathcal{J}(j))} \text{Res} \cdots \text{Res} \tilde{\Phi} \left( \mathcal{E}_b^{(j)} \oplus \bigoplus_{k=1}^{j} C_m \boxtimes Q^{(k)} \otimes e^{-h_k} \right) \Psi^{\mathcal{J}(j)} (\mathcal{E}_b^{(j)})
\]

\[
= \sum_{\mathcal{J}(j+1) \in \text{Dec}^{(j+1)}(c)} \int_{\tilde{M}(\mathcal{J}(j+1))} \text{Res} \cdots \text{Res} \tilde{\Phi} \left( \mathcal{E}_b^{(j+1)} \right. \\
\left. \oplus \bigoplus_{k=1}^{j+1} C_m \boxtimes Q^{(k)} \otimes e^{-h_k} \right) \Phi' (\mathcal{E}_b^{(j+1)})
\]

where

\[
\Phi' (\mathcal{E}_b^{(j+1)}) = \frac{v_1(c_b^{(j+1)})(v_1(c_b^{(j+1)}))!}{v_1(c_b^{(j)})!} \int_{\text{Gr}(m+1, p_{j+1})} \mathcal{J},
\]

\[
\mathcal{J} = \frac{\Psi^{\mathcal{J}(j)} (\mathcal{E}_b^{(j+1)} \oplus C_m \boxtimes Q^{(j+1)} \otimes e^{-h_{j+1}})}{e(\mathcal{M}(\mathcal{E}_b^{(j+1)}, C_m) \otimes Q^{(j+1)} \otimes e^{-h_{j+1}})} e((V_1(C_m) \otimes Q^{(j+1)} / \mathcal{O})^*)
\]

We have \( \Phi' (\mathcal{E}_b^{(j+1)}) = \Psi^{\mathcal{J}(j+1)} (\mathcal{E}_b^{(j+1)}) \) thanks to the multiplicative property of the Euler class and \( \mathcal{M}(C_m, C_m) = - \text{Hom}(C_m, C_m) = -C \text{id}_{C_m} \). Hence the formula holds for \( j + 1 \).

If \( j \) is sufficiently large, \( \text{Dec}^{(j)}(c) = \emptyset \). Hence we have

\[
\int_{\tilde{M}_{m+1}(c)} \Phi (\mathcal{E}) - \int_{\tilde{M}_m(c)} \Phi (\mathcal{E})
\]

\[
= \sum_{j=1}^{\infty} \sum_{\mathcal{J}(j) \in \text{Dec}^{(j)}(c)} \int_{\tilde{M}(\mathcal{J}(j))} \text{Res} \cdots \text{Res} \tilde{\Phi} \left( \mathcal{E}_b^{(j)} \oplus \bigoplus_{i=1}^{j} C_m \boxtimes Q^{(i)} \otimes e^{-h_i} \right) \times \Psi^{\mathcal{J}(j)} (\mathcal{E}_b^{(j)}).
\]
We have a map \( \rho_j : \text{Dec}^{(j)}(c) \to S_j(c) \) given by

\[
\rho_j(\gamma^{(j)}) = (c_0, p_1, \ldots, p_j) = \left( c^{(j)}_0, \frac{|I_1^{(j)}|}{m+1}, \ldots, \frac{|I_j^{(j)}|}{m+1} \right).
\]

Therefore the right-hand side is equal to

\[
\sum_{j=1}^{\infty} \sum_{c \in S_j(c)} \# \rho_j^{-1}(c) \frac{v_1(c)! \prod_{i=1}^j (p_i(m+1) - 1)!}{v_1(c)!} \prod_{i=1}^j \sum_{p_k}
\]

\[
\times \int_{\tilde{\mathcal{M}}(c_h)_{h_j=0}} \cdots \cdots \Phi \left( \mathcal{E}_s \oplus \bigoplus_{i=1}^j C_m \boxtimes \mathcal{Q}_i^{(j)} \otimes e^{-h_i} \right) \tilde{\psi}(\mathcal{E}_s).
\]

Thus Theorem 6.4 follows from the next lemma.

**Lemma 6.8 ([14, Lemma 7.6.6])**

We have

\[
\# \rho_j^{-1}(c) \frac{v_1(c)! \prod_{i=1}^j (p_i(m+1) - 1)!}{v_1(c)!} = \frac{1}{(m+1)^{j}} \prod_{i=1}^j \frac{1}{\sum_{1 \leq k \leq i} p_k}.
\]

**Proof**

The set \( \rho_j^{-1}(c) \) is

\[
\left\{ (I_b^{(j)}_1, I_b^{(j)}_2, \ldots, I_b^{(j)}_i) \mid \frac{|v_1(c)|}{v_1(c)} = I_b^{(j)}_1 \cup \bigcup_{j=1}^i I_b^{(j)}_j, \frac{|I_b^{(j)}|}{v_1(c)} = p_i(m+1), \text{min}(I_b^{(1)}) > \text{min}(I_b^{(2)}) > \cdots > \text{min}(I_b^{(i)}) \right\}.
\]

Put \( N := v_1(c) \), \( N_0 := v_1(c_0) \), \( N_i := p_i(m+1) \) (1 \( \leq i \leq j \)).

We first choose \( I_b^{(j)}_1 \subset N \). We have \( \binom{N}{N_0} \) possibilities. Next, we choose \( I_b^{(j)}_2 \subset N \setminus I_b^{(j)}_1 \). From the second condition, we must have \( \text{min}(I_b^{(j)}) = \text{min}(N \setminus I_b^{(j)}) \). Let \( x \) be this number. Then the remaining choice is \( I_b^{(j)} \setminus \{ x \} \subset (N \setminus I_b^{(j)}) \setminus \{ x \} \).

We have \( \binom{N-N_0-1}{N_i-1} \) possibilities. Next, we choose \( I_b^{(i-1)} \subset N \setminus (I_b^{(j)} \cup I_b^{(j)}) \). We have \( \binom{N-N_0-N_i-1}{N_j-1} \) possibilities. We continue until we choose \( I_b^{(1)} \). Therefore we have

\[
\# \rho_j^{-1}(c) = \binom{N}{N_0} \prod_{i=1}^j \left( \frac{N-N_0-\sum_{k\geq i} N_k-1}{N_i-1} \right)
\]

\[
= \frac{N!}{N_0! \prod_{i=1}^j (N_i-1)!} \times \prod_{i=1}^j \frac{1}{\sum_{1 \leq k \leq i} N_k}.
\]

Moreover,

\[
\prod_{i=1}^j \frac{1}{\sum_{1 \leq k \leq i} N_k} = \prod_{i=1}^j \frac{1}{\sum_{1 \leq k \leq i} p_k(m+1)}.
\]
