Supplemental Information

Distinct Microbial Communities Trigger Colitis Development upon Intestinal Barrier Damage via Innate or Adaptive Immune Cells

Urmí Roy, Eric J.C. Gálvez, Aida Iljazovic, Till Robin Lesker, Adrian J. Blażejewski, Marina C. Pils, Ulrike Heise, Samuel Huber, Richard A. Flavell, and Till Strowig
Supplemental information

**Supplemental experimental procedures:**

**Microbiota manipulation:** Alteration of microbiota composition was conducted by cohousing or fecal transplantation (Thieman et al., 2017). For cohousing both recipient and donor mice were cohoused at least 4 weeks prior starting experiment. For fecal transplantation donor mice were euthanized, intestinal content was collected in BBL thioglycollate media (BD Bioscience) and homogenized by vortexing. To remove course particle under anaerobic conditions the content was filtered through 70µm sterile filter. After centrifugation (10min, 500g, 4°C), the pellet containing fecal bacteria was resuspended in BHI medium (Sigma-Aldrich). After 2-hr of starving recipient mice were orally gavaged with a total 200ul of fecal bacterial content. Again a 4 week time period was given for a successful establishment of fecal transplanted bacteria (unless mentioned otherwise). Every microbiota manipulation was further confirmed by 16S rRNA sequencing of fecal bacteria.

**Histology:** At day 5 of DSS-treatment colon samples were collected, rolled up to “swiss roles”, fixed in 4% neutrally buffered formaldehyde and embedded in paraffin according to standard histological procedures. Sections of 3µm thickness were stained with hematoxylin-eosin (HE) and evaluated by light microscopy blinded to the experimental groups. The histological scoring used to evaluate the severity of colitis in DSS treated mice microscopically, was adapted from the TJL-score, which was developed for scoring colitis in mice by The Jackson Laboratory (Mähler et al., 1998). The alteration of the score has been previously described (Pils et al., 2010). The colon was divided into a proximal (oral), middle and distal (aboral) section, each of about the same size. The three sections were scored for the general criteria: severity (0-3), ulceration (0-3), oedema (0-3), goblet cell metaplasia (0-3), and area involved (0-3) where score 0 depicted no alteration to score 3 massive alteration in the given parameters. The scores were added up to a total of up to 15 per section and the scores of the three sections to a total of up to 45 per colon sample.

**Colonoscopy:** Colonoscopy was performed using a high-resolution mouse video endoscopic system (‘Coloview’, Carl Storz, Tuttingen, Germany). The severity of colitis was blindly scored using MEICS (Murine Endoscopic Index of Colitis Severity), which is based on five parameters: granularity of mucosal surface (0-3); vascular pattern (0-3); translucency of the colon mucosa (0-3); visible fibrin (0-3); and stool consistency (0-3) (Becker et al., 2007).

**Isolation of colonic lamina propria leukocytes (cLPL) and flow cytometry:** To isolate cLPL, density gradient centrifugation using Percoll was done as previously described (Weigmann et al., 2007). In brief, colons were collected during steady state and at d5 of DSS treatment. Fecal content was removed, tissues were opened longitudinally, washed with PBS and then shaken in HBSS containing 2 mM EDTA for 20 min at 37°C. Tissues were cut into small pieces and incubated with digestion solution (DMEM containing 1% fetal bovine serum (FBS), 0.25 mg/ml collagenase D, 0.5 U/ml dispase and 5 µg/ml DNase I) in a shaker for 20 min at 37°C. Digested tissues were filtered through 70µm cell strainer (Falcon) and DMEM + 5% FBS was added to inactivate enzymes. The last two steps were repeated until all tissue was digested. After centrifugation, cells were resuspended in 4 ml of 40% Percoll (GE Healthcare) and overlaid on 4 ml of 80% Percoll. Percoll gradient separation was performed by centrifugation at 450 g for 25 min at 25°C. Cells in the interphase were collected and used as LPL. The collected cells were then suspended in staining buffer containing PBS, 1% FBS and 2 mM EDTA. The following antibodies were used: anti-CD45 (30-F11), anti-CD3 (17A2), anti-B220 (RA3-6B2), anti-CD4 (RM4-5, GK1.5), anti-CD8a (53-6.7), anti-TCR-gamma/delta (GL3), anti-CD44 (IM7), anti-CD62L (MEL-14), anti-MHC class II (M5/114.15.2), anti-CD11b (M1/70), anti-CD11c (N418), anti-Ly6G (1A8), anti-Ly6C (HK1.4) (Biolegend). To distinguish live dead cells AlexaFluor-350 NHS Ester (Life Technologies) was used. Flow cytometry analysis was performed using a BD LSR (BD Biosciences) and data were analyzed with FlowJo software (TreeStar Inc.).

**In-vitro T cell activation of cLPL:** For T cell activation freshly isolated cLPL (200,000/well) were cultured in 96-well round-bottom plates in complete culture medium containing soluble, plate-bound, anti-CD3 (1mg/ml) and soluble anti CD28 (5mg/ml) (Biolegend) for 3 days. Supernatant were collected after 3 days for cytokines and chemokines measurement.
**Collection of colonic tissue homogenate:** Colonic tissue homogenate was collected from euthanized mice during steady state and d7 colitis. Colons were excised into proximal and distal colon. Each part was cut longitudinally and cleaned by washing with autoclaved 1x PBS. Parts of proximal or distal colon were weighed and homogenized mechanically using Mini-Beadbeater-96 (Biospec) in NP-40 lysis buffer containing protease inhibitors (Complete Mini EDTA-free, Roche). Protein extracts were centrifuged (10,000 r.p.m, for 5 min at 4°C) and the supernatants were collected as tissue homogenate samples and stored at -80°C.

**Cytokine detection- ELISA, multiplex and Legendplex:** Concentration of IL-18 in the tissue homogenates was measured using the following commercial ELISA kits: IL-18 (MBL) according to manufacturer’s instruction. Different other cytokines and chemokines were measured by using the ProcartaPlex Multiplex Immunoassay (eBioscience) and FACS based Legendplex kit (Biolegend) according to the manufacturer’s instructions.

**RNA isolation and quantitative PCR:** Tissues were preserved in RNAlater solution (Ambion) and subsequently homogenized in Trizol reagent (Invitrogen). One microgram of total RNA was used to generate cDNA by the protocol for first strand cDNA synthesis using RevertAid RT (Thermo Scientific). Real-Time-PCR was performed using gene-specific primer sets (Applied Biosystems) of Cd4 primer (F: 5’-TAGCAACTCTAAGGTCTCTAAC and R: 5’-GATAGCTGTGCTCTGAAAAC) and Kapa Sybr Fast qPCR kit (Kapa Biosystems) on a LightCycler 480 instrument (Roche). PCR conditions were 95°C for 60 s, followed by 40 cycles of 95°C for 3 s and 60°C for 30 s. Data were analyzed using the the deltaCt method with hprt (F: CTGGTGAAAAGGACCTCTCG and R: TGAAGTACTCATTATAGTCAAGGGCA) serving as the reference housekeeping gene.

**RNA-Seq Analysis:** Total RNA isolation from distal colonic tissue was performed as described at the RNA isolation section. RNA integrity was measured in a Bioanalyzer (Agilent Technologies, USA) and samples were selected according to RNA Integrity Number (RIN) > 9. Isolation of mRNA was performed with Dynabeads mRNA DIRECT Micro Kit (Ambion, USA) using 1ug of total RNA. Furthermore, cDNA synthesis, fragmentation and sequencing library preparation were done using ScriptSeq v2 RNA-Seq Kit (PCR 15 cycles) (Illumina, USA). Sequencing was performed through Illumia Hi-seq 2000 platform in single end mode for 50bp. Raw data is available in the SRA under accession number: PRJNA407361.

We obtained and average of 52,2Mio of reads per sample (n=16). Reads were quality filtered using Trimmomatic with as follow parameters (LEADING:3 TRAILING:3 SLIDINGWINDOW:4:15 MINLEN:35 HEADCROP:3). After quality control reads were aligned to the mouse reference genome (mm10) using STAR. Reads count to each gene was evaluated using HTseq. Normalization and differential expression were quantified using the DEseq2 package. Differential expressed gene networks were analyzed with Consensus Path DB-mouse webserver. Data was visualized using ggplot2 R library.

**Antibody-mediated depletion:** Anti-CD4 (clone GK1.5) and anti-CD8a (2.43) neutralizing antibodies and an isotype control mAb (clone LTF-2) (Bio X Cell) were used. For each antibody, 200ug injections were given intraperitoneally (i.p.) at day -1, day 3 and day 7 of DSS treatment. Isolating cLPL and splenic lymphocytes followed by flow cytometry assessed depletion efficiency.
Figure S1
Figure S1. Differences in microbiota composition of SPF mice regulate severity of acute inflammation upon barrier breakdown. Related to Figure 1

(A) Body weight on d8 of acute DSS colitis of SPF WT (SPF-1 – SPF-6) and dysbiotic Nlrp6\(^{-}\) (DysN6) mice described in Figure 1A.

(B) Analysis of fecal microbiota composition in SPF WT (SPF-1 – SPF-6) and dysbiotic Nlrp6\(^{-}\) (DysN6) mice before induction of DSS colitis using 16S rRNA sequencing. Analysis of \(\alpha\)-diversity (Chao1 and Shannon).

(C-D) Colon length was measured 5 days after induction of DSS colitis of SPF-1, SPF-2, SPF-4, SPF-6 and DysN6 (C). Histological analysis of distal colon was performed 5 days after induction of DSS colitis (D). Representative pictures of H&E-stained colon sections. Bar represents approx. 50\(\mu\)m.

Data represent n=6-18 mice/group as mean ± SEM from at least two independent experiments. \(p\) values indicated represent a unpaired Student’s t test. \(*p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.\)
Figure S2. Alteration of colitis susceptibility and distinct host response driven by colitogenic microbiota. Related to Figure 2

(A-B) Acute colitis was induced in SPF-1 WT mice cohoused with either SPF-2 WT or DysN6 Nlrp6<sup>−/−</sup> (SPF-1 + DysN6) mice resulting in SPF-1 + SPF-2 and SPF-1 + DysN6 mice, respectively. Survival of mice was monitored (A). Representative pictures and colitis severity score by colonoscopy performed on day 6 after colitis induction (B).

(C) SPF-6 WT mice were cohoused with SPF-2 WT resulting in SPF-6 (coh SPF-2) and SPF-2 (coh SPF-6) mice. Analysis of β-diversity (PCoA) of non-cohoused SPF-6 and cohoused SPF-6 (coh SPF-2) and SPF-2 (coh SPF-6) mice before induction of DSS colitis. Acute DSS colitis was induced and body weight of mice was monitored for 10 days.

(D) 16S rRNA sequencing of fecal microbiota from WT SPF-1, cSPF-2 and cDysN6 at d0 and d5 of DSS colitis was performed. Relative abundances of different microbial families are displayed.

(E) RNAseq analysis from total colonic tissue of WT mice colonized with SPF-1, cSPF-2 or cDysN6. DEseq analysis compares significant up/down-regulation of genes (fold change > 2) in different microbiota conditions.

Data represent n=4-16 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a unpaired Student’s t test (A) and nonparametric Kruskal-Wallis test (B) *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
Figure S3
Figure S3. Adaptive immune system is important for DysN6 mediated colitis. Related to Figure 3
(A) SPF-1 WT recipient mice were transferred with fecal content from Nlrp6−/− DysN6 or SPF-2 WT donor mice. Relative abundance of different bacterial families in fecal microbiota in mice with short (2d) and prolonged (28d) exposure to DysN6 and SPF-2 before DSS induction.
(B-C) SPF-1 WT and Rag2−/− recipients were cohoused with donor DysN6 or SPF-2 mice. Analysis of β-diversity (PCoA) of DysN6 recipients (B) and SPF-2 recipients (C) is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’.
(D-E) SPF-1 and cDysN6 WT and Rag2−/− were sacrificed on d5 of DSS colitis and colons were excised. Colon length was measured (D) and survival of mice with different microbiota are given (E). Data represent n=3-15 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a unpaired Student’s t test *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
Figure S4
Figure S4. Colitis driven by DysN6 and SPF-2 are characterized by distinct local infiltration of innate and adaptive immune cells and cytokine profile. Related to Figure 4
(A-B) DSS colitis was induced in WT mice harboring SPF-1, cDysN6 or cSPF-2 communities. Colon samples were collected at day 7 of DSS and divided into two parts as proximal (PC) and distal (DC) colon. Cytokines (A) and chemokines (B) were measured using Multiplex/LEGENDplex kit from colonic tissue homogenates.
(C-D) Colonic lamina propria leukocytes (cLPL) were isolated from WT mice harboring SPF-1, cDysN6 or cSPF-2 communities during steady state (d0) and d5 of DSS colitis and analyzed by FACS. Gating strategy of FACS data is displayed (C). Frequencies of different immune cells at d0 and d5 of DSS (D).
Data represent n=5-17 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a nonparametric Kruskal-Wallis test *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
Figure S5
Figure S5. $\alpha\beta$ T cells are required for DysN6 but not SPF-2 mediated colitis. Related to Figure 5

(A-D) SPF-1 WT, Tcrbd$^{-}$ and muMT$^{-}$ mice were cohoused with DysN6 donor mice. Fecal microbiota composition was analyzed by 16S rRNA sequencing before induction of DSS colitis. Analysis of $\beta$-diversity (PCoA) of SPF-1 and cDysN6 WT and Tcrbd$^{-}$ mice (A) or muMT$^{-}$ mice (B) is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’. Representative pictures and colitis severity score by colonoscopy performed on day 6 after colitis induction in SPF-1 and cDysN6 WT and Tcrbd$^{-}$ mice (C). Colon shortening was measured 5 days after colitis induction in SPF-1 and cDysN6 WT, Tcrbd$^{-}$ and muMT$^{-}$ mice (D).

(E-F) SPF-1 WT, Tcrbd$^{-}$ and muMT$^{-}$ were cohoused with SPF-2 donor mice. Fecal microbiota composition was analyzed by 16S rRNA sequencing before induction of DSS colitis. Analysis of $\beta$-diversity (PCoA) of SPF-1 and cSPF-2 WT and Tcrbd$^{-}$ mice (E) or muMT$^{-}$ mice (F) is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’.

(G) DSS colitis was induced in SPF-1 and cSPF-2 WT, Tcrbd$^{-}$ and muMT$^{-}$ mice. Body weight was monitored over 10 days after DSS induction.

(H-I) SPF-1 WT and Tcrd$^{-}$ mice were cohoused with DysN6 donor mice. Analysis of $\beta$-diversity (PCoA) of fecal microbiota from SPF-1 and cDysN6 WT and Tcrd$^{-}$ mice (H) is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’. Colon lengths of WT and Tcrd$^{-}$ mice 5 days after colitis induction were measured (I).

Data represent n=5-26 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a unpaired Student’s t test *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
Figure S6
Figure S6. Pathogenic CD4+ T cells are crucial for DysN6 but not SPF-2 to enhance colitis severity. Related to Figure 6

(A-C) SPF-1 WT, CD8− and CD4+ mice were cohoused with DysN6 donor mice. Fecal microbiota was analyzed by 16S rRNA sequencing before DSS induction and analysis of β-diversity (PCoA) of WT control, CD8− mice (A) and CD4+ mice (B) is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’. Representative pictures and total score after colonoscopy performed on day 6 after colitis induction in WT, CD8− and CD4+ mice harboring SPF-1 and cDysN6 communities (C).

(D-E) SPF-1 WT and CD4+ mice were cohoused with SPF-2 donor mice for 4 weeks. Fecal microbiota was analyzed by 16S rRNA before DSS induction and analysis of β-diversity (PCoA) of WT control, and CD4+ mice is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’ (D). Body weight was monitored for 10 days after inducing DSS (E).

(F) Colonic lamina propria leukocytes (cLPL) were isolated from SPF-1, cSPF-2 and cDysN6 IL-17A GFP IFN-γ Katushka Foxp3 RFP triple reporter mice during steady state (d0) and d5 of DSS colitis and analyzed by FACS. Representative FACS plots and percentage of different cytokine producing CD4+ T cells are displayed.

(G) T cell transfer colitis was induced by injecting CD4+Foxp3CD45RB(high) T cells into SPF-1, cDysN6 or cSPF-2 Rag2− recipients. Mice were sacrificed 16 days after T cell transfer. Lymphocytes were isolated from colon and analyzed by FACS. Infiltration of different cytokine producing cell population in colon is displayed.

Data represent n=5-20 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a unpaired Student’s t test (C,E) and nonparametric Kruskal-Wallis test (F,G) *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
Figure S7
Figure S7. CD4+ T cells drives DSS colitis severity in DysN6 but not SPF-2 mice by recognizing antigens from dominant microbial members. Related to Figure 7.

(A-B) SPF-1 WT and OTII transgenic mice were cohoused with DysN6 donor mice for 4 weeks. Analysis of β-diversity (PCoA) of fecal microbiota from SPF-1 and cDysN6 WT and OTII transgenic mice is shown along with multivariate analysis of variance (ADONIS test) of variables ‘microbiota composition’, ‘genotype’ and ‘cage’ (A). Colon length of SPF-1 and cDysN6 WT and OTII transgenic mice after 5 days of DSS induction were measured (B).

(C-D) DSS colitis was induced in SPF-1 and cSPF-2 WT and OTII transgenic mice and body weight was monitored for 10 days.

(E) RNAseq analysis from total colonic tissue of WT mice harboring different communities. Heatmap shows quantification of RNA reads and DEseq analysis to identify significant up/down-regulation (fold change >2) of genes in SPF-1 and cDysN6+SPF-2 conditions.

(F) Relative Cd4 expression in colonic tissue of mice harboring different microbiota.

(G-H) DSS colitis was induced in WT mice colonized with SPF-1 and cDysN6+SPF-2 communities. At d5 of DSS mice were sacrificed and colon length was measured (G). Histological analysis of distal colon was performed 5 days after induction of DSS colitis (H). Representative pictures of H&E-stained colon sections. Bar represents approx. 50µm.

Data represent n=5-20 mice/group as mean ± SEM from at least two independent experiments. P values indicated represent a unpaired Student’s t test (B-D, G, H) and nonparametric Kruskal-Wallis test (F) *p < 0.05; **p < 0.01; ***p< 0.001; ****p< 0.0001.
