Abstract. This article presents results being consistent with conjectures of J.-L. Loday about the existence and properties of a Leibniz homology for groups. Introducing L-sets we prove that (pointed) rack homology has properties this conjectural Leibniz homology should satisfy, namely the existence of a coZinbiel coalgebra structure on rack homology and the existence of a non trivial natural cocommutative coalgebra morphism from the rack homology of a group to its Eilenberg-MacLane homology. The end of the paper treats the particular cases of the linear group and of abelian groups. We prove the existence of a connected coZinbiel-associative bialgebra structure on their rack homology.

Introduction

Chevalley-Eilenberg homology and Leibniz homology. The Chevalley-Eilenberg homology is the natural homology theory associated to Lie algebras (cf. [CE56]). The Koszul dual of the operad Lie encoding Lie algebras is the operad Com encoding commutative algebras. Therefore the Chevalley-Eilenberg homology of a Lie algebra is naturally provided with a cocommutative coalgebra structure (cf. [LV12]).

\[ H_\bullet(\cdot, k) : \text{Lie} \to \text{Com}^c \]

Given a Lie algebra \( g \) this homology theory is the homology of a chain complex whose underlying graded vector space is the exterior algebra \( \Lambda(g) \). A fundamental remark due to J.-L. Loday is that using the antisymmetry of the Lie bracket it is possible to rewrite the differential in such a way that the relation \( d^2 = 0 \) is a consequence of the Leibniz relation only.

\[ [[x, y], z] = [x, [y, z]] + [x, [z, y]] \]

As a consequence the differential on the Chevalley-Eilenberg chain complex lifts up to a differential \( d_L \) on the tensor vector space \( T(g) \). It defines a new chain complex \( (T(g), d_L) \), and so a new homology theory called Leibniz homology (cf. [Lod98]). Because the Leibniz relation is the only relation involved in the definition of \( d_L \), this complex \( (T(g), d_L) \) is defined for a category of algebras containing the category of Lie algebras. These algebras have been dubbed Leibniz algebras by J.-L. Loday. More precisely a Leibniz algebra is a vector space \( g \) provided with a bilinear map \( \{-, -\} : g \times g \to g \) called Leibniz bracket (or shortly bracket) satisfying the Leibniz relation. The operad Leib encoding Leibniz algebras being Koszul dual to the operad Zinb encoding Zinbiel \( ^1 \)algebras, the Leibniz homology of a Leibniz algebra is naturally provided with a coZinbiel coalgebra structure.

\[ H_L(\cdot, k) : \text{Leib} \to \text{Zinb}^c \]

At the operad level the morphism \( \text{Leib} \to \text{Lie} \) induces a morphism \( \text{Com} \to \text{Zinb} \), so there is a commutative diagram:

\[
\begin{array}{ccc}
\text{Leib} & \xrightarrow{H_L(\cdot, k)} & \text{Zinb}^c \\
\downarrow & & \downarrow \\
\text{Lie} & & \text{Com}^c \\
\end{array}
\]

2010 Mathematics Subject Classification. 17A32, 20N99.

Key words and phrases. Leibniz algebra, Zinbiel algebra, rack, cubical set.

\(^1\)Zinbiel algebras are Koszul dual to Leibniz algebras and are sometimes called dual Leibniz algebras; the word Zinbiel is Leibniz spelled backward.
Moreover the canonical projection $T(g) \to \Lambda(g)$ induces a natural map of cocommutative algebras in homology $HL_n(G, k) \to H_n(G, k)$ fitting into a long exact sequence.

$$\cdots \to H_n^{rel}(G, k) \to HL_n(G, k) \to H_n(G, k) \to H_n^{rel}(G, k) \to \cdots$$

**Chevalley-Eilenberg homology and Leibniz homology of abelian Lie algebras** (cf. [Lod93]). The Chevalley-Eilenberg and Leibniz differentials of an abelian Lie algebra are trivial. Therefore $H_n(G, k) \simeq \Lambda^n(g)$ and $HL_n(G, k) \simeq T^n(g)$ for all $n \in \mathbb{N}$, and the morphism from Leibniz homology to Chevalley-Eilenberg homology is the canonical projection $T(g) \to \Lambda(g)$.

**Chevalley-Eilenberg homology and Leibniz homology of the Lie algebra of matrices $gl(A)$** (cf. [Lod98]).

Given a unital associative algebra $A$ over a field of characteristic $0$, the Chevalley-Eilenberg and the Leibniz homologies of the Lie algebra of matrices $gl(A)$ are provided with more structure.

There is a product on $gl(A)$, called the direct sum of matrices, which induces a connected commutative graded Hopf algebra structure on the Chevalley-Eilenberg homology of $gl(A)$. As a consequence if we combine the Hopf-Borel theorem and the Loday-Quillen-Tsygan theorem, then we obtain the following isomorphism of Hopf algebras

$$H_n(gl(A), k) \simeq S(HC_{n-1}(A))$$

where $HC_{n}(A)$ is the cyclic homology of $A$.

The direct sum of matrices induces a connected graded coZinbiel-associative bialgebra structure on the Leibniz homology of $gl(A)$. As a consequence if we combine this structure theorem and the Loday-Cuvier theorem, then we obtain the following isomorphism of coZinbiel-associative bialgebras

$$HL_n(gl(A), k) \simeq T(HH_{n-1}(A))$$

where $HH_{n-1}(A)$ is the Hochschild homology of $A$.

**Eilenberg-MacLane homology and conjectural Leibniz homology for groups.** The *Eilenberg-MacLane homology* is the natural homology theory associated to groups (cf. [CE56]). This homology theory is naturally associated with a cocommutative coalgebra structure.

$$H_*(-, k) : Grp \to Com^c$$

Lie algebras being the linearized objects associated to groups, the existence and properties of the Leibniz homology theory for Lie algebras and Leibniz algebras led J.-L. Loday to state this conjecture.

**Conjecture** (J.-L. Loday [Lod93, Lod03]). *There exists a Leibniz homology theory defined for groups which is naturally endowed with a coZinbiel coalgebra structure.*

$$HL_*(-, k) : Grp \to Zinb^c$$

This Leibniz homology is related to the usual group homology by a natural morphism of cocommutative algebras.

$$HL_*(G, k) \to H_*(G, k)$$

This Leibniz homology is the natural homology theory of mathematical objects called coquecigrues whose groups carry naturally the structure.
Eilenberg-MacLane homology and conjectural Leibniz homology of abelian groups. Eilenberg-MacLane homology of an abelian group is well known (cf. [Bro94]). It is provided with a graded Hopf algebra structure, and for a field $k$ of characteristic 0 there is an isomorphism $H_n(G,k) \simeq \Lambda^n(G \otimes k)$ for all $n \in \mathbb{N}$. Abelian Lie algebras being linearized objects associated to abelian groups, the similar properties satisfied by the Chevalley-Eilenberg homology and the Leibniz homology of an abelian Lie algebra led J.-L. Loday to state the following conjecture.

**Conjecture** (J.-L. Loday [Lod93, Lod03]). The Leibniz homology of an abelian group $G$ is provided with a connected coZinbiel-associative bialgebra structure. Moreover for all $n \in \mathbb{N}$ there is an isomorphism $HL_n(G,k) \simeq T^n(G \otimes k)$, and if the characteristic of $k$ is 0, then the natural morphism from $HL_n(G,k)$ to $H_n(G,k)$ is the canonical projection $T^n(G \otimes k) \to \Lambda^n(G \otimes k)$.

Eilenberg-MacLane homology and conjectural Leibniz homology of the linear group $GL(R)$. The Eilenberg-MacLane homology of the (infinite) linear group $GL(R)$ is provided with a connected commutative graded Hopf algebra structure (cf. [Lod98]). The Lie algebra of matrices $gl(A)$ being the linearized object associated to the linear group, the similar properties satisfied by the Chevalley-Eilenberg homology and the Leibniz homology of $gl(A)$ led J.-L. Loday to state the following conjecture.

**Conjecture** (J.-L. Loday [Lod93, Lod03]). The Leibniz homology of the linear group $GL(R)$ is provided with a connected coZinbiel-associative bialgebra structure.

**Results.** A natural candidate for this conjectural Leibniz homology is the natural homology theory of objects integrating Leibniz algebras. A rack is a mathematical object which encapsulates some properties of the conjugation in a group (cf. [Joy82]). There are at least two ways to construct a Leibniz algebra from a rack, a geometric one due to M.K. Kinyon ([Kim97]) and an algebraic one due to S. Danco ([Dan11]), and reciprocally any Leibniz algebra integrates into a local Lie rack (cf. [Cov13]). As a consequence it is natural to suspect the homology theory of racks to be linked to this conjectural Leibniz homology theory.

In this article we prove that rack homology satisfies most of the properties a Leibniz homology for groups should satisfy. These results are the contents of the following theorems.

**Algebraic structure on rack homology and relation with Eilenberg-MacLane homology.**

**Theorem.** The rack homology of a rack $X$ is naturally provided with a coZinbiel coalgebra structure

$$HR_*(-,k) : \text{Rack} \to \text{Zinb}^\mathbb{C},$$

and there is a natural morphism $S_* : HR_*(G,k) \to H_*(G,k)$ of cocommutative coalgebra from the rack homology of a group $G$ to its Eilenberg-MacLane homology fitting in a long exact sequence.

$$\cdots \to H_{n+1}(G,k) \to HR_n(G,k) \xrightarrow{S_*} H_n(G,k) \to H^{rel}_n(G,k) \to \cdots$$

**Rack homology of abelian groups.**

**Theorem.** The rack homology of an abelian group $(G,+)$ is provided with a connected coZinbiel-associative bialgebra structure where the associative product is induced by the rack morphism $+ : G \times G \to G$. Moreover for all $n \in \mathbb{N}$ there is an isomorphism $HR_n(G,k) \simeq T^n(k[G \setminus \{0\}])$, and if the characteristic of $k$ is 0, then the natural morphism from $HR_n(G,k)$ to $H_n(G,k)$ is the canonical map $T^n(k[G \setminus \{0\}]) \to \Lambda^n(G \otimes k)$.

**Rack homology of the linear group $GL(R)$.**

**Theorem.** The rack homology of the linear group $GL(R)$ is provided with a connected coZinbiel-associative bialgebra structure where the associative product is induced by the direct sum of matrices.

The plan for this article is the following.

**Section 1 : (co)Dendriform and (co)Zinbiel (co)algebras.** This section is based on [LV12] and [Bur10]. It recalls definitions about (co)dendriform and (co)Zinbiel (co)algebras, together with definitions and a structure theorem about coZinbiel-associative bialgebras.
Section 2: L-sets. This section is the core of our paper where we define the new notion of L-sets. The category of L-sets, denoted LSet, is a full subcategory of the category cSet of cubical sets. First we prove the existence of left and right adjoint L, \( \Gamma : \text{LSet} \to \text{cSet} \) to the forgetful functor U : LSet \to cSet. \[ \Gamma \dashv U \dashv L \]

By construction there exists of a long exact sequence relating the homology of a cubical set X and the homology of the L-set L(X) naturally associated to it.

\[ \cdots \to H_{n+1}^{rel}(X, k) \to H_n(L(X), k) \to H_n(X, k) \to H_{n+1}^{rel}(X, k) \to \cdots \]

We finish this section with the proof of the existence of a coZinbiel coalgebra structure on the homology of any L-set (Theorem 2.9) using the method of the acyclic models.

Section 3: L-homology of groups and rack homology. In this section we compute the L-set \( L(N^2 G) \) associated to the cubical nerve of a group \( G \). The importance of the cubical nerve is that its homology is isomorphic to the Eilenberg-MacLane homology of the group. We prove that \( L(N^2 G) \) is isomorphic to the nerve of the rack \( G \) (Proposition 3.2). This result implies that the L-homology of the cubical set \( L(N^2 G) \) is exactly the rack homology of \( G \). With the results proved in the previous section, we deduce the existence of a coZinbiel coalgebra structure on rack homology (Theorem 3.4) and the existence of a morphism from the rack homology of a group to its Eilenberg-MacLane homology fitting into a long exact sequence (Theorem 3.5).

Section 4: Rack homology of abelian groups. In this section we focus on the particular case of abelian groups. First the definition of the graded Hopf algebra structure on the Eilenberg-MacLane homology of an abelian group is recalled, together with the computation of the Eilenberg-MacLane homology groups of an abelian group. Then we prove the existence of a coZinbiel-associative bialgebra structure on the rack homology of an abelian group, and we compute the rack homology groups of an abelian group.

Section 5: Rack homology of the linear group. In this section we focus on the particular case of the linear group GL(\( R \)). First we recall the definition of the graded Hopf algebra structure on the Eilenberg-MacLane homology of GL(\( R \)). Then we prove the existence of a coZinbiel-associative bialgebra structure on its rack homology (Theorem 5.6).

Appendix A: Acyclic models. This appendix is a summary of [EM53]. It recalls definitions and theorems of the Eilenberg-MacLane theory about acyclic models.

Appendix B: Simplicial and cubical sets. This appendix recalls definitions and properties of simplicial and cubical sets. Especially we remind the construction of a cocommutative coalgebra structure on the homology of a cubical set using the method of acyclic models.

1. (co)Dendriform and (co)Zinbiel (co)algebras

1.1. Shuffle. For all \( n \in \mathbb{N}^\ast \) let \( S_n \) be the group of permutations of the set \( \{1, \ldots, n\} \). For all \( p, q \in \mathbb{N}^\ast \) let \( \text{Sh}_{p, q} \) be the subset of elements \( \sigma \in S_{p+q} \) satisfying

\[ \sigma(1) < \cdots < \sigma(p) \quad \text{and} \quad \sigma(p+1) < \cdots < \sigma(p+q). \]

Such an element \( \sigma \) is called a \( (p, q) \)-shuffle. Remark that \( \sigma(1) = 1 \) or \( \sigma(1) = p+1 \). The subset of \( (p, q) \)-shuffles satisfying \( \sigma(1) = 1 \) (resp. \( \sigma(1) = p+1 \)) is denoted by \( \text{Sh}^1_{p,q} \) (resp. \( \text{Sh}^{p+1}_{p,q} \)).

There is a bijection \( \text{Sh}_{p,q} \cong \text{Sh}_{q,p} \) given by

\[ \iota(\sigma)(k) := \begin{cases} \sigma(k+p) & \text{if } 1 \leq k \leq q, \\ \sigma(k-q) & \text{if } q+1 \leq k \leq p+q. \end{cases} \]

For all \( p, q, r \in \mathbb{N}^\ast \) let \( \text{Sh}_{p,q,r} \) be the subset of elements \( \sigma \in S_{p+q+r} \) satisfying

\[ \sigma(1) < \cdots < \sigma(p) \quad \text{and} \quad \sigma(p+1) < \cdots < \sigma(p+q) \quad \text{and} \quad \sigma(p+q+1) < \cdots < \sigma(p+q+r). \]

Such an element \( \sigma \) is called a \( (p,q,r) \)-shuffle.
For all $p, q, r \in \mathbb{N}^*$ there are bijections $\text{Sh}_{p+q, r} \times \text{Sh}_{p, q} \cong \text{Sh}_{p+q, r} \times \text{Sh}_{p, q}$ given by

$$\alpha(\sigma, \gamma)(k) := \begin{cases} \sigma(\gamma(k)) & \text{if } 1 \leq k \leq p + q, \\ \sigma(k) & \text{if } p + q + 1 \leq k \leq p + q + r. \end{cases}$$

$$\beta(\sigma, \gamma)(k) := \begin{cases} \sigma(k) & \text{if } 1 \leq k \leq p, \\ \sigma(p + \gamma(k - p)) & \text{if } p + 1 \leq k \leq p + q + r. \end{cases}$$

1.2. **Dendriform (co)algebra** (LV12). A (graded) dendriform algebra is a graded vector space $A$ endowed with two products $\langle, \rangle : A \otimes A \to A$ satisfying the following relations called dendriform relations:

$$\begin{align*}
(x \langle y) & \langle z = x \langle (y \langle z + y \rangle z), \\
(x \rangle y) & \langle z = x \langle (y \langle z), \\
x \rangle (y \rangle z) & = (x \rangle y + x \langle y) \rangle z.
\end{align*}$$

A dendriform algebra $(A, \langle, \rangle)$ is said to be unital if there exists an element $1 \in A$ such that $1 \langle x = x \rangle 1 = 0$ and $1 \rangle x = x \langle 1 = x$ for all $x \in A$. Note that $1 \langle 1$ and $1 \rangle 1$ are not defined. Given a dendriform algebra $(A, \langle, \rangle)$, the product $\star := \langle + \rangle$ on $A$ is associative. Therefore there exists a functor between categories of algebras $\text{Dend} \to \text{As}$. By duality we get the definition of a codendriform coalgebra. A (graded) codendriform coalgebra is a graded vector space $C$ endowed with two coproducts $\Delta_\prec, \Delta_\succ : C \to C \otimes C$ satisfying the following relation called codendriform relation:

$$\begin{align*}
(\Delta_\prec \otimes \text{id}) \circ \Delta_\prec & = (\text{id} \otimes \Delta_\prec + \text{id} \otimes \Delta_\succ) \circ \Delta_\prec, \\
(\Delta_\succ \otimes \text{id}) \circ \Delta_\prec & = (\text{id} \otimes \Delta_\prec) \circ \Delta_\prec, \\
(\text{id} \otimes \Delta_\succ) \circ \Delta_\prec & = (\Delta_\prec \otimes \text{id} + \Delta_\succ \otimes \text{id}) \circ \Delta_\prec.
\end{align*}$$

A codendriform coalgebra is said to be counital if there exists a linear map $c : C \to k$ such that $(c \otimes \text{id}) \circ \Delta_\succ = (\text{id} \otimes c) \circ \Delta_\succ = 0$ and $(c \otimes \text{id}) \circ \Delta_\prec = (\text{id} \otimes c) \circ \Delta_\prec = \text{id}$. Note that $(c \otimes c) \circ \Delta_\prec$ and $(c \otimes c) \circ \Delta_\succ$ are not defined.

Given a codendriform coalgebra $(A, \Delta_\prec, \Delta_\succ)$, the coproduct $\Delta := \Delta_\prec + \Delta_\succ$ on $A$ is cocommutative. Therefore there exists a functor between categories of coalgebras $\text{Dend}^\text{c} \to \text{As}^\text{c}$.

1.3. **(co)Zinbiel (co)algebra** (LV12). A (graded) Zinbiel algebra is a graded vector space $A$ endowed with a product $\prec : A \otimes A \to A$ satisfying the following relation called (graded) Zinbiel relation:

$$(x \prec y) \prec z = x \prec (y \prec z + (-1)^{|x||y|} z \prec y).$$

A Zinbiel algebra $(A, \prec)$ is said to be unital if there exists an element $1 \in A$ such that the following is verified $1 \prec x = 0$ and $x \prec 1 = x$ for all $x \in A$. Note that $1 \prec 1$ is not defined. Given a Zinbiel algebra $(A, \prec)$, the products $\prec$ and $\succ := \tau \circ \prec$ define a dendriform algebra structure on $A$. Therefore there exists a functor between categories of algebras $\text{Zinb} \to \text{Dend}$. The product $\star := \prec + \prec \circ \tau$ on $A$ is associative and commutative. Therefore there exists a functor between categories of algebras $\text{Zinb} \to \text{Com}$.

By duality we get the definition of a coZinbiel coalgebra. A (graded) coZinbiel coalgebra is a graded vector space $C$ endowed with a coproduct $\Delta_\prec : C \to C \otimes C$ satisfying the following relation called coZinbiel relation:

$$(\Delta_\prec \otimes \text{id}) \circ \Delta_\prec = (\text{id} \otimes \Delta_\prec + \text{id} \otimes (\tau \circ \Delta_\prec)) \circ \Delta_\prec.$$
Let \((\overline{C}, \Delta^-)\) be a coZinbiel coalgebra. A filtration of \(\overline{C}\) is defined by

\[
F_r\overline{C} := \{x \in \overline{C} \mid \Delta^- (x) = 0\} \\
F_r\overline{C} := \{x \in \overline{C} \mid \Delta^- (x) \in F_{r-1}\overline{C} \otimes F_{r-1}\overline{C}\} \text{ for all } r > 1
\]

The coZinbiel coalgebra \(\overline{C}\) is said to be connected (or conilpotent) if \(\overline{C} = \bigcup_{r \geq 1} F_r\overline{C}\). The space of primitive elements of \(\overline{C}\) is the first piece of the filtration.

\[
\text{Prim}(\overline{C}) := F_1\overline{C}
\]

Given a coZinbiel coalgebra \((A, \Delta^-)\), the coproducts \(\Delta_\prec \) and \(\Delta_\succ = \tau \circ \Delta_\prec \) define a codendriform coalgebra structure on \(A\). Therefore there exists a functor between categories of algebras \(\text{Zinb}^\prime \rightarrow \text{Dend}^\prime\). The coproduct \(\Delta := \Delta_\prec + \tau \circ \Delta_\succ\) on \(A\) is coassociative and cocommutative. Therefore there exists a functor between categories of algebras \(\text{Zinb}^\prime \rightarrow \text{Com}^\prime\).

**Example 1.1.** Let \(V\) be a graded vector space. Let us define a coZinbiel coproduct on the reduced tensor vector space \(T(V)\) by:

\[
(1) \quad \Delta^-(x_1 \cdots x_n) := \sum_{p+q=n} \sum_{\sigma \in \text{Sh}_{p,q}} \epsilon(\sigma) x_1 x_{\sigma(2)} \cdots x_{\sigma(p)} \otimes x_{\sigma(p+1)} \cdots x_{\sigma(p+q)}
\]

This coproduct is called the half-shuffle coproduct.

1.4. **coZinbiel-associative bialgebra** ([Bur10]). A (graded) coZinbiel-associative bialgebra \((H, \star, \Delta^-)\) is a graded vector space \(H\) endowed with a counital coZinbiel coproduct \(\Delta^- : H \rightarrow H \otimes H\) and an associative product \(\star : H \otimes H \rightarrow H\) satisfying the following compatibility relation called semi-Hopf relation:

\[
\Delta^-_\prec \circ \star = \star \otimes (\Delta^- \otimes \Delta^-).
\]

**Example 1.2.** The graded vector space \(T(V)\) with the concatenation product and the half-shuffle coproduct \((\text{L})\).

1.5. **Structure theorem for coZinbiel-associative bialgebras** ([Bur10]). The Hopf-Borel theorem is a structure theorem for (graded) Hopf algebras. This theorem states that a connected comutative graded Hopf algebra over a field of characteristic 0 is free and cofree over its primitive part. As a consequence such a Hopf algebra is isomorphic to \((S(V), \cdot, \Delta_{Sh})\) where \(V\) is its primitive part, \(\cdot\) the canonical symmetric product on \(S(V)\) and \(\Delta_{Sh}\) the shuffle coproduct.

In the case of a coZinbiel-associative bialgebra a similar structure theorem holds.

**Theorem 1.3.** ([Bur10]) A connected coZinbiel-associative bialgebra (over a field of any characteristic) is free and cofree over its primitive part.

As a consequence a connected coZinbiel-associative bialgebra is isomorphic as a bialgebra to \(T(V)\) where \(V\) is its primitive part (cf. Example 1.2).

2. **L-sets**

In this section we introduce L-sets. These objects are cubical sets (cf. [B,G]) for which the cocommutative coalgebra structure on the homology is induced by a coZinbiel coalgebra structure.

2.1. **L-sets.** A L-set is a cubical set \(X\) such that \(X_0 = \{\star\}\), and for all \(n \in \mathbb{N}\)

\[
d_{1,0} = d_{1,1} : X_n \rightarrow X_{n-1}
\]

By definition a L-set is a cubical set, thus there is a functor \(U\) from the category \(\text{LSet}\) of L-set to the category \(\text{cSet}\) of cubical set

\[
U : \text{LSet} \rightarrow \text{cSet}.
\]
2.2. The category \( L \). A \( L \)-set can be defined as a contravariant functor from a certain category \( L \) to the category \( \text{Set} \) in the following way. Let \( L \) be the category with the same objects as \( \Box \), but with set of morphisms \( \text{Hom}_L(\Box_m, \Box_n) \) from \( \Box_m \) to \( \Box_n \) defined as the coequalizer of \( d_{1,1} \) and \( d_{1,0} \).

\[
\text{Hom}_L(\Box_m, \Box_n) \xrightarrow{d_{1,1}} \text{Hom}_L(\Box_m, \Box_n) \xrightarrow{\text{coeq}(d_{1,0}, d_{1,1})} \text{Hom}_L(\Box_m, \Box_n)
\]

Thanks to the universal property of a quotient category, there is a projection functor from \( \Box^{op} \) to \( L^{op} \) and each \( L \)-set \( X \) factorizes in a unique way through the category \( L^{op} \).

\[
\text{□}^{op} \xrightarrow{X} \text{Set} \xrightarrow{L} \text{□}
\]

As a consequence the category of \( L \)-set is equivalent to the category of functors from \( L^{op} \) to \( \text{Set} \).

\[
\text{LSet} \simeq [L^{op}, \text{Set}]
\]

2.3. The functors \( L \) and \( \Gamma \). In this section we construct a left and a right adjoint to the forgetful functor \( U : \text{LSet} \to \mathfrak{cSet} \).

Let \( L \) be the functor from \( \mathfrak{cSet} \) to \( \text{LSet} \) defined on objects by \( LX_0 = \{\ast\} \) and for all \( n \geq 1 \)

\[
LX_n = \bigcap_{1 \leq k \leq n} \bigcap_{e, e' \in (0,1)^k} \text{eq}(d_{1,e_1} \cdots d_{1,e_k}; d_{1,e'_1} \cdots d_{1,e'_k}) \subseteq X_n,
\]

\( LX(d_{e,e'}) = \overline{d_{e,e'}} \) (well defined thanks to the cubical identities), and on morphisms by declaring that \( Lt_0 \) is the unique map from \( \ast \to \ast \) and \( Lt_n = t_{LX_n} \) for all \( n \geq 1 \). There is a natural transformation \( \text{inc} : L \to \text{id}_{\mathfrak{cSet}} \) from \( L \) to the identity functor induced by the inclusions \( LX_n \subseteq X_n \).

Let \( \Gamma \) be the functor from \( \mathfrak{cSet} \) to \( \text{LSet} \) defined on objects by \( \Gamma X_0 = \{\ast\} \) and for all \( n \geq 1 \)

\[
\Gamma X_n = \text{coeq}(d_{1,0}; d_{1,1})
\]

and \( \Gamma X(d_{e,e'}) = \overline{d_{e,e'}} \) (well defined thanks to the cubical identities), and on morphisms by declaring that \( \Gamma t_0 \) is the unique map from \( \ast \to \ast \) and \( \Gamma t_n = \overline{t_n} \). There is a natural transformation \( \text{proj} : \text{id}_{\mathfrak{cSet}} \to \Gamma \) from the identity functor to \( \Gamma \) induced by the projections \( X_n \to \Gamma X_n \).

There are adjunctions \( \Gamma \dashv U \) and \( U \dashv L \), and the functors \( L \) and \( \Gamma \) satisfy the relations \( L \circ L = L \), \( \Gamma \circ \Gamma = \Gamma \), \( \Gamma \circ L = L \) and \( L \circ \Gamma = \Gamma \). As a consequence a cubical set \( X \) is a \( L \)-set if and only if \( X = LX = \Gamma X \).

2.4. Representable contravariant functors of \( L \). For all \( n \in \mathbb{N} \) let us denote by \( L^n \) the representable functor \( \text{Hom}_L(\Box_n, \Box_n) \). By definition \( L^n = \Gamma^n \).

**Lemma 2.1.** The restrictions of functors \( Q_n \) and \( C_n \) (cf. \[L^3\] to \( \text{LSet} \) are representable by \( k.L^n \).

**Proof.** Let \( n \in \mathbb{N} \) be fixed and take as set of models \( \mathcal{M} \) the set with one element \( \{k.L^n\} \). By definition the functor \( Q_n \) is the composition of the functor \( k. : \text{Set} \to \mathfrak{kMod} \) and the evaluation functor \( \text{ev}_{\Box_n} : \text{LSet} \to \text{Set} \)

\[
Q_n := k. \circ \text{ev}_{\Box_n}.
\]

Let us define a natural transformation \( \Psi \) from \( Q_n \) to \( \bar{Q}_n \) (cf. \[A.1\]) by the formula

\[
\Psi_X : Q_n(X) \to \bar{Q}_n(X); \Psi_X(x) = (\phi_x, \overline{\text{id}_{\Box_n}}),
\]

where \( \phi_x \) is the unique natural transformation from \( L^n \) to \( X \) such that \( (\phi_x)_n(\overline{\text{id}_{\Box_n}}) = x \) (Yoneda’s Lemma). We have \( \Phi \circ \Psi = \text{id} \) so \( Q_n : \text{LSet} \to \mathfrak{kMod} \) is representable.
The representability of $C_n$ is a consequence of Lemma A.1. Indeed, let $\xi : Q_n \to C_n$ be the natural transformation defined by passing to the quotient, and let $\eta : C_n \to Q_n$ be the natural transformation defined by

$$\eta_x := (\text{id} - s_1d_{1,0}) \cdots (\text{id} - s_nd_{n,0}).$$

Thanks to the cubical identities this map sends $D_n(X)$ to 0 and so is well defined. Moreover $\xi \circ \eta = \text{id}$ then by Lemma A.1 the functor $C_n$ is representable.

**Lemma 2.2.** For all $n \in \mathbb{N}$, $H_\bullet(L^n, \mathbb{k}) = \begin{cases} 0 & \text{if } \bullet \neq 1, \\ \mathbb{k}^n & \text{if } \bullet = 1. \end{cases}$

**Proof.** Let $n \in \mathbb{N}$ be fixed. The homology of $L^n$ is isomorphic to the singular homology of its geometric realization $[L^n]$. This topological space is homeomorphic to the quotient of $[0, 1]^n$ by the equivalence relation identifying $(d_{i_1}, \cdots, d_{i_k})$ for all $x \in [0, 1]^n$, $1 \leq k \leq n$ and $i_1, \cdots, i_k \in \{0, 1\}$.

Let $\{A_i, B_i\}_{1 \leq i \leq n}$ be a family of subspace of $[L^n]$ defined by:

- $A_i := \{ (x_1, \ldots, x_n) \in [0, 1]^n \mid x_i \neq \frac{1}{2} \}$,
- $B_i := \{ (x_1, \ldots, x_n) \in [0, 1]^n \mid x_1 \leq \frac{1}{2} \}$. where $p : [0, 1]^n \to [L^n]$ is the projection. Thanks to the properties

- $A_1 \cup B_1 = [L^n]$,
- $A_1 \cap B_1 \simeq \{*, 1\}$,
- $B_1 \simeq \{*, 1\}$,

the Mayer-Vietoris exact sequence applied to the covering $[L^n] = A_1 \cup B_1$

$$\cdots \to H_{p+1}([L^n]) \to H_p(A_1 \cap B_1) \to H_p(A_1) \oplus H_p(B_1) \to H_p([L^n]) \to H_{p-1}(A_1 \cap B_1) \to \cdots,$$

proves that

$$H_p([L^n]) = \begin{cases} H_p(A_1) \oplus \mathbb{k} & \text{if } p > 1, \\ H_1(A_1) \oplus \mathbb{k} & \text{if } p = 1. \end{cases}$$

Thanks to the properties

- $A_1 \cup B_2 = [L^n]$,
- $(A_1 \cap A_2) \cap (A_1 \cap B_2) \simeq \{*, 1\}$,
- $A_1 \cap B_2 \simeq \{*, 1\}$,

the Mayer-Vietoris exact sequence applied to the covering $A_1 = (A_1 \cap A_2) \cup (A_1 \cap B_2)$ proves that

$$H_p(A_1) = \begin{cases} H_p(A_1 \cap A_2) & \text{if } p > 1, \\ H_1(A_1 \cap A_2) \oplus \mathbb{k} & \text{if } p = 1. \end{cases}$$

Applying successively this procedure leads to:

$$H_p([L^n]) = \begin{cases} H_p(A_1 \cap \cdots \cap A_n) \oplus \mathbb{k}^{n-1} & \text{if } p > 1, \\ H_1(A_1 \cap \cdots \cap A_n) & \text{if } p = 1. \end{cases}$$

Therefore

$$H_p([L^n]) = \begin{cases} 0 & \text{if } p > 1, \\ \mathbb{k}^n & \text{if } p = 1. \end{cases}$$

□

2.5. **L-homology of cubical sets.** Let $X$ be a cubical set. For all $n \in \mathbb{N}$ let us denote by $QL_n(X)$ the module $Q_n(LX)$, and by $CL_n(X)$ the quotient of $QL_n(X)$ by the subspace $DL_n(X) := D_n(X) \cap QL_n(X)$. These constructions are natural in $X$ and so induce functors

$$QL_n : \text{cSet} \to \text{kMod} \text{ and } CL_n : \text{cSet} \to \text{kMod}.$$
Thanks to cubical identities, the degree $-1$ graded map $d = \sum_{i=1}^n (-1)^{i+1}(d_{i,1} - d_{i,0})$ defines chain complex structures on graded modules $QL_\bullet(X)$ and $CL_\bullet(X)$. These constructions are natural in $X$ and so induce functors

$$QL_\bullet : \text{cSet} \to \text{Ch}^+ \text{ and } CL_\bullet : \text{cSet} \to \text{Ch}^+.$$  

The unnormalized $L$-homology of $X$, denoted $HL^n(X)$, is the homology of the chain complex $QL_\bullet(X)$. The $L$-homology of $X$, denoted $HL_\bullet(X)$, is the homology of the chain complex $CL_\bullet(X)$.

2.6. A long exact sequence relating $H_\bullet$ and $HL_\bullet$. The natural transformation $\text{inc} : L \to \text{id}_{\text{cSet}}$ induces natural transformations $C_\bullet(\text{inc})$ from $CL_\bullet$ to $C_\bullet$ and $H_\bullet(\text{inc})$ from $HL_\bullet$ to $H_\bullet$. Then we get a short exact sequence (natural in $X$) in the category of chain complexes

$$CL_\bullet(X) \to C_\bullet(X) \to C_\bullet^{\text{rel}}(X) = C_\bullet(X)/CL_\bullet(X),$$

which induces a long exact sequence (natural in $X$)

$$\cdots \to H^{\text{rel}}_{n+1}(X) \to HL_n(X) \to H_n(X) \to H^{\text{rel}}_n(X) \to \cdots$$

2.7. A long exact sequence relating $H_\bullet$ and $H^\text{sub}_\bullet$. The natural transformation $\text{proj} : \text{id}_{\text{cSet}} \to \Gamma$ induces natural transformations $C_\bullet(\text{proj})$ from $CL_\bullet$ to $C_\Gamma$ and $H_\bullet(\text{proj})$ from $HL_\bullet$ to $H^\Gamma_\bullet$. Then we get a short exact sequence (natural in $X$) in the category of chain complexes

$$\text{Ker}(C_\bullet(\text{proj})) = : C_\bullet^{\text{sub}}(X) \hookrightarrow C_\bullet(X) \to C_\Gamma(X),$$

which induces a long exact sequence (natural in $X$)

$$\cdots \to H^{\text{sub}}_n(X) \to H_n(X) \to H^\Gamma_n(X) \to H^{\text{sub}}_{n-1}(X) \to \cdots$$

2.8. A differential graded dendriform coalgebra structure on the Leibniz complex. Let $X$ be a cubical set. Let us define two degree 0 maps $\Delta_>$ ($X$) and $\Delta_<$ ($X$) from $CL_\bullet(X)$ to $CL_\bullet(X) \otimes CL_\bullet(X)$ by the following formulas:

$$\Delta_>(X)\alpha = \bigoplus_{p+q=n} \sum_{\sigma \in S_{p+q}^1} e(\sigma) (d_{\sigma(p+1),0} \cdots d_{\sigma(p+q),0})(x) \otimes (d_{1,1} \cdots d_{\sigma(1),1})(x)$$

and

$$\Delta_<(X)\alpha = \bigoplus_{p+q=n} \sum_{\sigma \in S_{p+q}^1} e(\sigma) (d_{1,0} \cdots d_{\sigma(p+q),0})(x) \otimes (d_{\sigma(1),1} \cdots d_{\sigma(1),1})(x)$$

for all $x \in X_n$ and $n \geq 2$. With enough stamina it is possible to check that these formulas define chain complex morphisms. A more conceptual way to prove that such chain morphisms exist and are homotopy unique is to use once again the acyclic models method: Indeed, define $\Delta_>$ and $\Delta_<$ in dimensions 2 by the formulas (3) and (4). These maps induce natural transformations between homology functors

$$\Delta_>: \Delta_>: HL_2(-,-) \to HL_1(-,-) \otimes HL_1(-,-).$$

To define $\Delta_>$ and $\Delta_<$ in higher dimensions we use the acyclic models method. By Proposition 2.1 the functor $CL_\bullet$ is representable by $L^n$ for all $n \in \mathbb{N}$, and by Proposition 2.2 the homology groups $H_p(CL_\bullet(L^n) \otimes CL_\bullet(L^n))$ vanish for all $p > 2$ and $n \in \mathbb{N}$. The acyclic models theorems 3 and 4 imply that there are homotopy unique natural transformations $\Delta_>$ and $\Delta_<$ extending those already defined in dimensions 2.

**Theorem 2.3.** Let $X$ be a cubical set. Then $(CL_\bullet(X), \Delta_>, \Delta_<)$ is a homotopy coZinbiel coalgebra (in the category of chain complexes).

**Proof.** The maps $(\text{id} \otimes \Delta_>) \circ \Delta_>$ and $(\Delta \otimes \text{id}) \circ \Delta_>$ are two maps from $CL_\bullet$ to $C_{\bullet} \otimes C_{\bullet} \otimes C_{\bullet}$ which coincide in degree 3. The acyclic model theorem 4 implies that these two maps are homotopic. In the same way we prove that $(\text{id} \otimes \Delta_<) \circ \Delta_\prec \simeq (\Delta_\succ \otimes \text{id}) \circ \Delta_\prec$ and $(\Delta_\prec \otimes \text{id}) \circ \Delta_\prec \simeq (\text{id} \otimes \Delta) \circ \Delta_\prec$. Therefore $(CL_\bullet(X), \Delta_>, \Delta_<)$ is a homotopy codendriform coalgebra.
First we prove that there exist a homotopy in dimension 2 from $\Delta_n$ to $\tau \circ \Delta_n$. Then for higher dimensions the result will be a consequence of the acyclic models theorem \[A.4\] In dimension 2 we have

$$\Delta_n (X)(x) - (\tau \circ \Delta_n)(X)(x) = (d_{1,0} x \otimes d_{2,1} x) - (-d_{1,1} x \otimes d_{2,0} x) = d_{1,0} x \otimes dx = (id \otimes d)(d_{1,0} x \otimes x).$$

Then $h : CL_n \to (CL \otimes CL)[1]$ defined by $h(X)(x) := d_{1,0} x \otimes x$ is a homotopy of dimensions $\leq 2$ from $\Delta_n$ to $\tau \circ \Delta_n$. The acyclic model theorem \[A.4\] implies that the maps $\Delta_n$ and $\tau \circ \Delta_n$ are homotopic. As a consequence $(CL_n(X), \Delta_n, \Delta_n)$ is a homotopy coZinbiel coalgebra.

\[\Box\]

**Corollary 2.4.** Let $X$ be a cubical set. Then $(HL_n(X, k), \Delta)$ is a connected coZinbiel coalgebra (in the category of graded vector space).

3. L-homology for groups and rack homology

In this section we compute explicitly the L-set associated to the cubical nerve of a group $G$. We proved that the associated Leibniz chain complex is exactly the chain complex which computes the rack homology of $G$. We deduce from this result and the previous section the existence of a coZinbiel coalgebra structure on the rack homology of a group $G$ and the existence of a long exact sequence relating group homology and rack homology. More generally we prove that rack homology is provided with a coZinbiel coalgebra structure.

3.1. Cubical and simplicial nerves of a category. Let $C$ be a category. The cubical nerve of $C$ is the cubical set $N^\square C := Hom_{cSet}(-, C) : \square^{op} \to \text{Set}$, and the simplicial nerve of $C$ is the simplicial set $N^\Delta C := Hom_{cSet}(-, C) : \Delta^{op} \to \text{Set}$. Using these functorial constructions we define two functors from $\text{Cat}$ to $\text{Ch^+} : C \circ N^\square$ and $C \circ N^\Delta$.

```
\[
\begin{array}{ccc}
\text{Cat} & \overset{N^\square}{\longrightarrow} & \text{cSet} \\
N^\Delta & \downarrow & \text{cSet} \\
\text{sSet} & \overset{C_*}{\longrightarrow} & \text{Ch^+}
\end{array}
\]
```

**Theorem 3.1.** Let $C$ be a category. The chain complexes $C_*(N^\square C)$ and $C_*(N^\Delta C)$ are quasi isomorphic.

**Proof.** Define $S$ in dimension $0$ by $S_0 := id : C_0(N^\square C) \to C_0(N^\Delta C)$. By induction we extend this map to a morphism of chain complexes which is unique up to homotopy using acyclic models theorems. Indeed, by Lemma \[B.9\] the functor $C_*$ is representable by $\square^n$ for all $n \in \mathbb{N}$, and by Lemma \[B.10\] the homology groups $H_{n-1}(C_*(\Delta^n))$ vanish for all $n \geq 2$. The acyclic models theorems \[A.3\] and \[A.4\] imply the existence of a homotopy unique morphism of chain complexes $S : C_*(N^\square C) \to C_*(N^\Delta C)$ extending $S_0$.

In the same way Lemma \[B.4\] and Lemma \[B.10\] imply that there exists a homotopy unique morphism of chain complexes $S^{-1} : C_*(N^\Delta C) \to C_*(N^\square C)$ extending $S_0^{-1} := id : C_0(N^\Delta C) \to C_0(N^\square C)$.

The chain map $S \circ S^{-1}$ coincides with $id : C_*(N^\Delta C) \to C_*(N^\Delta C)$ in dimension $0$. The acyclic models Theorem \[A.4\] implies that these two chain maps are homotopic. In the same way $S^{-1} \circ S$ is homotopic to $id : C_*(N^\Delta C) \to C_*(N^\Delta C)$.

An explicit formula for $S = \{S_n\}_{n \in \mathbb{N}}$ is given by

$$S_n := \sum_{\sigma \in \Sigma_n} \epsilon(\sigma) \sigma^*$$

where $\sigma$ is the functor from $\Delta_n$ to $\square_n$ defined by $\sigma(i) := \{\sigma(1), \ldots, \sigma(i)\}$. 
3.2. Cubical and simplicial nerves of a group. Let \( G \) be a group. We still denote by \( G \) the groupoid with set of objects \( \{e\} \) and set of morphisms \( G \). The composition is defined using the group multiplication:

\[
e - g \to e - h \to e := e - g \circ h
\]

The identity is given by the neutral element in \( G \):

\[
\text{id}_e := e \to e
\]

The cubical and simplicial nerves of \( G \) are respectively the cubical and simplicial sets \( N^\square G \) and \( N^\Delta G \) of the groupoid \( G \). Let us denote by \( C^\square_n(G, k) \) and \( C^\Delta_n(G, k) \) the chain complexes respectively associated to the cubical and simplicial nerves of \( G \). By Theorem 3.2, these two chain complexes are quasi isomorphic, and so there is an isomorphism of their associated homologies

\[
H^\square_n(G, k) \simeq H^\Delta_n(G, k).
\]

A direct computation proves that the simplicial nerve \( N^\Delta G \) of the groupoid \( G \) is isomorphic to the nerve \( NG \) of the group \( G \) defined by

\[
NG := G^n,
\]

\[
NG(\delta_i)(g_1, \ldots, g_n) := \begin{cases}
(g_2, \ldots, g_n) & \text{if } i = 0, \\
(g_1, \ldots, g_{i+1}, g_{i+1}, \ldots, g_n) & \text{if } 1 \leq i \leq n, \\
(g_1, \ldots, g_{n-1}) & \text{if } i = n,
\end{cases}
\]

\[
NG(\sigma_i)(g_1, \ldots, g_n) := (g_1, \ldots, g_{i-1}, e, g_{i+1}, \ldots, g_n).
\]

Therefore there are isomorphisms between cubical homology, simplicial homology and Eilenberg-MacLane homology.

\[
H^\square_n(G, k) \simeq H^\Delta_n(G, k) \simeq H_*(G, k).
\]

3.3. Computation of the \( L \)-nerve \( L(N^\square G) \) of a group \( G \). Let \( G \) be a group. Let \( N^R G \) be the cubical set defined by

\[
N^R G_n := G^n,
\]

\[
N^R(\delta_i)(g_1, \ldots, g_n) := \begin{cases}
(g_1, \ldots, g_{i-1}, 1, g_{i+1}, \ldots, g_n) & \text{if } \epsilon = 0, \\
(g_1, \ldots, g_{i-1}, 1, g_{i+1}, \ldots, g_n) & \text{if } \epsilon = 1.
\end{cases}
\]

\[
N^R(\sigma_i)(g_1, \ldots, g_n) := (g_1, \ldots, g_{i-1}, 1, g_{i+1}, \ldots, g_n).
\]

**Proposition 3.2.** The cubical sets \( L(N^\square G) \) and \( N^R G \) are isomorphic.

**Proof.** First, let us compute \( L(N^\square G) \) for all \( n \in \mathbb{N} \). Let \( n \in \mathbb{N} \) and \( F \in L(N^\square G)_n \) be fixed. Let us prove that \( F \) is completely and uniquely determined by its image on the morphisms \( \emptyset \to \{i\} \) for all \( 1 \leq i \leq n \).

In other words let us prove that the map

\[
(5) \quad F \to (F(\emptyset \to \{1\}), F(\emptyset \to \{2\}), \ldots, F(\emptyset \to \{n\})),
\]

is a bijection from \( L(N^\square G)_n \) to \( G^n \).

By definition \( F \) is a functor from \( \square_n \) to \( G \), so

\[
F(A \to B) = F(A \to A \sqcup \{i_1\}) \cdots F(A \sqcup \{i_1, \ldots, i_{k-1}\} \to B)
\]

for all morphisms \( A \to B \) in \( \square_n \), with \( B = A \sqcup \{i_1, \ldots, i_k\} \) where \( i_1 < \cdots < i_k \). Then \( F \) is determined by its images on morphisms of the form \( A \to A \sqcup \{i\} \) with \( i > \text{max}(A) \). Moreover

\[
A \to A \sqcup \{i\} = \delta_A(\delta_2, \ldots, \delta_{n-i+1})(\emptyset \to \{1\}) \quad \text{and} \quad \emptyset \to \{i\} = \delta_0(\delta_2, \ldots, \delta_{n-i+2})(\emptyset \to \{1\}),
\]

then

\[
F(A \to A \sqcup \{i\}) = (\delta_d)^{n-i-2}d_AF(\emptyset \to \{1\}) = (\delta_d)^{n-i-2}d_kF(\emptyset \to \{1\}) = F(\emptyset \to \{i\}).
\]

Thus the map \( 5 \) is a bijection between \( L(N^\square G)_n \) and \( G^n = N^R G_n \).
Now let us compute the maps $d_{i,\epsilon} : L(N_{\square}G)_n \to L(N_{\square}G)_{n-1}$ for all $1 \leq i \leq n$ and $\epsilon \in \{0, 1\}$ under the bijection (5). Let $F \in L(N_{\square}G)_n$ and $(g_1, \ldots, g_n)$ be its corresponding element in $G^n$ under the bijection (5). We have

\[
(d_{i,\epsilon}F)(0 \to \{j\}) = \begin{cases} 
F(\emptyset \to \{j\}) = g_j & \text{if } i > j, \epsilon = 0, \\
F(\emptyset \to \{j + 1\}) = g_{j+1} & \text{if } i \leq j, \epsilon = 0, \\
F(\{i\} \to \{j, i\}) = F(\{i\} \to \emptyset \to \{j\} \to \{j, i\}) = g_i^{-1}g_jg_i & \text{if } i > j, \epsilon = 1, \\
F(\{i\} \to \{i, j + 1\}) = F(\emptyset \to \{j + 1\}) = g_{j+1} & \text{if } i \leq j, \epsilon = 1,
\end{cases}
\]

Finally let us compute the maps $s_i : L(N_{\square}G)_n \to L(N_{\square}G)_{n+1}$ for all $1 \leq i \leq n + 1$ under the bijection (5). Let $F \in L(N_{\square}G)_n$ and $(g_1, \ldots, g_n)$ be its corresponding element in $G^n$ under the bijection (5). We have

\[
(s_iF)(0 \to \{i\}) = \begin{cases} 
F(\emptyset \to \{j\}) = g_j & \text{if } i > j, \\
F(\text{id}_\emptyset) = e & \text{if } i = j, \\
F(\emptyset \to \{j - 1\}) = g_{j-1} & \text{if } i < j.
\end{cases}
\]

Thus (5) induces an isomorphism between the cubical sets $L(N_{\square}G)$ and $N^R G$. □

A consequence of (2.3) is that the homology of the cubical set $N^R(G)$ is provided with a coZinbiel coalgebra structure. This result is consistent with the conjecture of J.-L. Loday about the existence of a Leibniz homology defined for groups provided with a coZinbiel coalgebra structure.

\[
\text{HL}_n(\mathbb{Z}_p, G) := H_\bullet \circ C_\bullet(\mathbb{Z}_p, G) \circ \text{ker}(\text{Grp}) \to \text{Zinb}^e
\]

In the following part we prove that the $L$-homology defined on the category of groups can be extended to a larger category called the category of racks. On this category of racks the $L$-homology functor becomes the usual rack homology functor.

3.4. Rack homology. Let $G$ be a group. Theorem 3.2 emphasizes that the maps $d_{i,\epsilon}$ and $s_i$ are defined using only the conjugation in $G$ and not the product in $G$. Moreover we can check that the cubical relations are consequences of the following identities:

\[
e \triangleleft g = e,\]
\[
g \triangleleft e = g,\]
\[
(k \triangleleft h) \triangleleft g = (k \triangleleft g) \triangleleft (h \triangleleft g),
\]

where $h \triangleleft g = g^{-1}hg$. As a consequence this cubical set can be defined in general for any set $X$ provided with an operation $\triangleleft : X \times X \to X$ satisfying these identities. This remark leads to the notion of (pointed) rack.

Definition 3.3. A rack is a set $X$ provided with a product $\triangleleft : X \times X \to X$ satisfying the rack identity (8) for all $g, h, k \in X$, and such that the map $- \triangleleft g : X \to X$ is a bijection for all $g \in X$. A pointed rack is a rack $(X, e)$ provided with an element $e \in X$, called neutral element, satisfying equations (7) and (8) for all $g \in X$.

In the sequel all racks will be considered pointed. Given a rack $X$ there is a cubical set $N^R X$, called the nerve of $X$, and defined by the following formulas.

\[
N^R X_n := X^n,
\]
\[
N^R X(\delta_{i,\epsilon})(x_1, \ldots, x_n) := \begin{cases} 
\{x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n\} & \text{if } \epsilon = 0, \\
\{x_1 \triangleleft x_1, \ldots, x_{i-1} \triangleleft x_{i-1} \triangleleft x_{i+1}, \ldots, x_n\} & \text{if } \epsilon = 1.
\end{cases}
\]

The chain complex associated to this cubical set is called the rack chain complex of $X$ and is denoted by $\text{CR}_\bullet(X, k)$. Its homology is called the rack homology of $X$ and is denoted by $\text{HR}_\bullet(X, k)$.

The nerve of a rack $X$ is a $L$-set, therefore the rack chain complex of $X$ is provided with a homotopy coZinbiel coalgebra structure.
Theorem 3.4. Let $X$ be a rack. The rack homology of $X$ is provided with a coZinbiel coalgebra structure.

$HR_*(-, k) : \text{Rack} \to \text{Zinb}^c$

Given $n \in \mathbb{N}$ an explicit formula for $(\Delta)_n : HR_n(X, k) \to \bigoplus_{p+q=n} HR_p(X, k) \otimes HR_q(X, k)$ is:

$$(\Delta)_n[x_1, \ldots, x_n] = \sum_{p+q=n} \sum_{\sigma \in S_n} \epsilon(\sigma) \left[ x_{\sigma(1)} x_{\sigma(2)} \cdots x_{\sigma(p)} \right] \otimes \left[ x_{\sigma(p+1)} \cdots x_{\sigma(n)} \right]$$

where $x_i^p := x_{\sigma(i)} < x_{i_1} < \cdots < x_{i_k}$ with $i_j \in \{\sigma(1), \ldots, \sigma(p)\}$ and $i_k > \cdots > i_1 > \sigma(i)$.

The functor $\text{Conj} : \text{Grp} \to \text{Rack}$ from the category of groups to the category of racks makes the following diagram commutative:

$$\begin{array}{ccc}
\text{Rack} & \xrightarrow{HR_*(-, k)} & \text{Zinb}^c \\
\downarrow{\text{Conj}} & & \downarrow{\text{HL}_*(-, k)} \\
\text{Grp} & \xrightarrow{\text{HR}_*(-, k)} & \text{Zinb}^c
\end{array}$$

where $\text{HL}_*(-, k)$ is defined by (10). This result is consistent with the conjecture of J.-L. Loday about the existence of mathematical objects (coquecigrues) whose groups naturally carry the structure and whose natural homology theory is provided with a coZinbiel coalgebra structure.

The long exact sequence (2) applied to the nerve of a group induces the following theorem relating rack homology and group homology.

**Theorem 3.5.** Let $G$ be a group. There is a long exact sequence

$$\cdots \to HR_{n+1}^G(G, k) \to HR_n(G, k) \xrightarrow{\partial_n} H_n(G, k) \to HR_{n-1}(G, k) \to \cdots$$

Given $n \in \mathbb{N}$ an explicit formula for $S_n : HR_n(G, k) \to H_n(G, k)$ is:

$$S_n(g_1, \ldots, g_n) = \sum_{\sigma \in S_n} \epsilon(\sigma) (g_{\sigma(1)}, \ldots, g_{\sigma(n)})$$

where $g_i^p := g_{\sigma(i)} < g_{i_1} < \cdots < g_{i_k}$ with $i_j \in \{\sigma(1), \ldots, \sigma(i-1)\}$ and $i_k > i_{k-1} > \cdots > i_1 > \sigma(i)$.

This result is consistent with the conjecture of J.-L. Loday about the existence of a natural morphism of cocommutative coalgebras from Leibniz homology to the usual group homology.

4. Rack homology of abelian groups

In this section $G$ is an abelian group and $\mu : G \times G \to G$ is the commutative multiplication in $G$. Group homology of abelian groups with coefficients in a field of characteristic 0 is well known. Using the Pontryagin product we can prove for all $n \in \mathbb{N}$ the following isomorphism (cf. [Hro91] pp.121).

$$H_n(G, k) \simeq \Lambda^n(G \otimes k)$$

There is a similar result for the rack homology of an abelian group. This is the content of the following theorem.

**Theorem 4.1.** Let $G$ be an abelian group. For all $n \in \mathbb{N}$ there is an isomorphism

$$HR_n(G, k) \simeq T^n(k[G \setminus \{0\}]).$$

If $k$ is a field of characteristic 0, then under bijections (10) and (11) the map $S_n : HR_n(G, k) \to H_n(G, k)$ is the canonical projection $T^n(k[G \setminus \{0\}]) \to \Lambda^n(G \otimes k)$ for all $n \in \mathbb{N}$.

**Proof.** The group $G$ being abelian the conjugation is trivial. It implies that the differential of the chain complex $CR_*(-, k)$ is equal to zero. Therefore the homology groups $HR_n(G, k)$ are isomorphic to $CR_n(G, k) = k[G^n] \simeq k[G]^{\otimes n}$ for all $n \in \mathbb{N}$.

The conjugation in $G$ being trivial the map $S_n : HR_n(G, k) \to H_n(G, k)$ is equal to $S_n(g_1, \ldots, g_n) = \sum_{\sigma \in S_n} \epsilon(\sigma) (g_{\sigma(1)}, \ldots, g_{\sigma(n)})$ for all $n \in \mathbb{N}$. Under bijections (10) and (11) this map is the canonical projection. □
4.1. A commutative Hopf algebra structure on the group homology of an abelian group.

The group $G$ being abelian the multiplication $\mu$ is a group morphism. As a consequence the chain complex $C_\bullet(G,k)$ computing the group homology of $G$ is provided with a product $\star$, called Pontryagin product, and defined by the formula

$$\star : C_\bullet(G,k) \otimes C_\bullet(G,k) \xrightarrow{\text{Eilenberg-Zilber map}} C_\bullet(G \times G,k) \xrightarrow{\text{cup product}} C_\bullet(G,k).$$

where $\text{EZ}$ is the Eilenberg-Zilber map, an inverse to the Alexander-Whitney map. An explicit formula for $\star$ is given by

$$F \ast F' := \sum_{\sigma \in 	ext{Sh}_{p,q}} \epsilon(\sigma) \mu \circ (F \times F') \circ \sigma$$

for all $F \in C_p(G,k)$, $F' \in C_q(G,k)$. In this formula $\sigma$ is the functor from $\Delta_{p+q}$ to $\Delta_p \times \Delta_q$ defined by

$$\sigma(j) := \left\{ \begin{array}{ll}
(\sigma^{-1}(j), j - \sigma^{-1}(j)) & \text{if } 1 \leq \sigma^{-1}(j) \leq p, \\
(j - \sigma^{-1}(j) + p, \sigma^{-1}(j) - p) & \text{if } p + 1 \leq \sigma^{-1}(j) \leq p + q.
\end{array} \right.$$  

Under the bijection $C_n(G,k) \simeq \mathbb{k}G^n$ the product $\ast$ is equal to

$$(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q}) = \sum_{\sigma \in \text{Sh}_{p,q}} \epsilon(\sigma)(g_{\sigma^{-1}(1)}, \ldots, g_{\sigma^{-1}(p+q)}).$$

This product is associative and commutative and thus provides $C_\bullet(G,k)$ with a commutative algebra structure. Previously we have seen that $C_\bullet(G,k)$ is provided with a cocommutative up to homotopy coalgebra structure (Theorem [B.11]). These two structures are compatible, i.e. they satisfy the Hopf relation

$$\Delta \circ \ast = \ast \circ (\Delta \otimes \Delta).$$

Therefore the group homology of an abelian group $G$ with coefficients in a field $k$ is a commutative Hopf algebra. This Hopf algebra is connected so Theorem [1.3] implies that the Hopf algebra $(H_\bullet(G,k), \Delta, \ast)$ is free and cofree over its primitive part.

4.2. A coZinbiel-associative bialgebra structure on the rack homology of an abelian group.

The multiplication $\mu : G \times G \to G$ being a group morphism it is a rack morphism. As a consequence the chain complex $CR_\bullet(G,k)$ computing the rack homology of $G$ is provided with a product $\star$, still called the Pontryagin product, and defined by the same formula as before.

$$\star : CR_\bullet(G,k) \otimes CR_\bullet(G,k) \xrightarrow{\text{Eilenberg-Zilber map}} CR_\bullet(G \times G,k) \xrightarrow{\text{cup product}} CR_\bullet(G,k).$$

An explicit formula for $\star$ on $CR_\bullet(G,k)$ is given by:

$$F \ast F' = \mu \circ (F \times F') \circ i_{p,q}$$

where $i_{p,q}$ is the functor from $\square_{p+q}$ to $\square_p \times \square_q$ defined by $i_{p,q}(t_1, \ldots, t_{p+q}) = ((\epsilon_1, \ldots, \epsilon_p), (\epsilon_{p+1}, \ldots, \epsilon_{p+q})).$

Under the bijection $CR_\bullet(G,k) \simeq \mathbb{k}G^n$ the product $\ast$ is equal to

$$(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q}) = (g_1, \ldots, g_{p+q}).$$

This product is associative and thus provides $CR_\bullet(G,k)$ with an associative algebra structure. Previously we have seen that $CR_\bullet(G,k)$ is provided with a coZinbiel up to homotopy coalgebra structure (Theorem [2.3]). These two structures are compatible, i.e. they satisfy the semi-Hopf relation

$$\Delta_{\otimes} \circ \ast = \ast \circ (\Delta_{\otimes} \otimes \Delta).$$

Therefore the rack homology of an abelian group $G$ with coefficients in a field $k$ is a coZinbiel-associative bialgebra. This bialgebra is connected so Theorem [1.3] implies that the coZinbiel-associative bialgebra $(HR_\bullet(G,k), \Delta_{\otimes}, \ast)$ is free and cofree over its primitive part.
5. Rack homology of the linear group

Let \( R \) be a ring with unit and \( \text{GL}_n(R) \) be the group of invertible \( n \times n \) matrices. Let \( \oplus \) be the associative product defined on the graded group \( \{\text{GL}_n(R)\}_{n \in \mathbb{N}} \) by the formula:

\[
A \oplus B := \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix}.
\]

The linear group with coefficients in \( R \) \( \text{GL}(R) \) is the inductive limit of the system \( \{i_{m,n} : \text{GL}_m(R) \hookrightarrow \text{GL}_n(R)\}_{m,n \in \mathbb{N}} \) where \( i_{m,n}(A) = A \oplus I_{n-m} \) (\( I_p \) is the identity matrix on \( R^p \)).

For all \( n \in \mathbb{N}^* \) let \( \mu_n : \text{GL}_n(R) \times \text{GL}_n(R) \rightarrow \text{GL}_{2n}(R) \) be the group morphism defined by

\[
\mu_n(A, B) := \begin{cases} 
0 & \text{if } i \neq j \text{ mod } 2, \\
\frac{a_{i+1,j+1} + a_{i+1,j}}{2} & \text{if } i = j = 1 \text{ mod } 2, \\
\frac{b_{i,j}}{2} & \text{if } i = j = 0 \text{ mod } 2.
\end{cases}
\]

The family of maps \( \{\mu_n\}_{n \in \mathbb{N}^*} \) induces a group morphism \( \mu : \text{GL}(R) \times \text{GL}(R) \rightarrow \text{GL}(R) \). The class of the identity matrices in \( \text{GL}(R) \) will be denoted by \( e \).

A relation between \( \mu_n \) and \( \oplus \) is given by the following lemma.

**Lemma 5.1.** For all \( n \in \mathbb{N}^* \) there exists \( C_n \in \text{GL}_{2n}(R) \) such that for all \( A, B \in \text{GL}_n(R) \)

\[
\mu_n^{-1}(A, B)C_n = A \oplus B.
\]

**Proof.** Take \( C_n = \prod_{1 \leq i \leq 2n-1} C_{i,i+1} \) where \( C_{i,i+1} \) is the matrix exchanging columns \( i \) and \( i+1 \). \( \square \)

**Lemma 5.2.** For all \( m, n \in \mathbb{N}^* \) there exists \( D_{m,n} \in \text{GL}_{m+n}(R) \) such that for all \( A \in \text{GL}_m(R), B \in \text{GL}_n(R) \)

\[
D_{m,n}^{-1}(A \oplus B)D_{m,n} = B \oplus A.
\]

**Proof.** Take \( D_{m,n} := \begin{bmatrix} 0 & L_n \\ L_m & 0 \end{bmatrix} \). \( \square \)

### 5.1. A commutative Hopf algebra structure on the group homology of the linear group

In this section we recall how to define a graded Hopf algebra structure on the group homology of the linear group \( \text{GL}(R) \). Here we use a direct method but one can look at [Lod98] or [Ros94] for a topological construction using the \( H \)-space structure of \( \text{BGL}(R)^+ \).

The group morphism \( \mu \) induces a product \( \ast \) on \( C_\ast(\text{GL}(R), k) \), called the Pontryagin product, and defined by the formula

\[
\ast : C_\ast(\text{GL}(R), k) \otimes C_\ast(\text{GL}(R), k) \xrightarrow{\Delta} C_\ast(\text{GL}(R) \times \text{GL}(R), k) \xrightarrow{\mu} C_\ast(\text{GL}(R), k).
\]

An explicit formula for \( \ast \) is given by

\[
F \ast F' := \sum_{\sigma \in \Sigma_{p,q}} \epsilon(\sigma) \mu \circ (F \times F') \circ \sigma
\]

for all \( F \in C_p(G, k), F' \in C_q(G, k) \). In this formula \( \sigma \) is the functor from \( \Delta_{p+q} \) to \( \Delta_p \times \Delta_q \) defined as before by

\[
\sigma(j) := \begin{cases} 
(\sigma^{-1}(j), j - \sigma^{-1}(j)) & \text{if } 1 \leq \sigma^{-1}(j) \leq p, \\
(j - \sigma^{-1}(j) + p, \sigma^{-1}(j) - p) & \text{if } p + 1 \leq \sigma^{-1}(j) \leq p + q.
\end{cases}
\]

Under the bijection \( C_n(\text{GL}(R), k) \simeq k \cdot \text{GL}(R)^n \) the product \( \ast \) is equal to

\[
(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q}) = \sum_{\sigma \in \Sigma_{p,q}} \epsilon(\sigma) (g_{\sigma^{-1}(1)}^\mu, \ldots, g_{\sigma^{-1}(p+q)}^\mu),
\]

where \( g_i^\mu = \begin{cases} 
\mu(g_i, e) & \text{if } 1 \leq i \leq p, \\
\mu(e, g_i) & \text{if } p + 1 \leq i \leq p + q.
\end{cases} \)
Proposition 5.3. The product $\ast$ on $\operatorname{H}(\operatorname{GL}(R), k)$ is associative and commutative.

One topological way to prove this proposition is to use the topological space $\operatorname{BGL}(R)^+$. The product $\mu$ endows the space $\operatorname{BGL}(R)^+$ with an associative and commutative $H$-space structure, and, using the isomorphism between the singular homology of $\operatorname{BGL}(R)^+$ and the group homology of $\operatorname{GL}(R)$, we deduce the associativity and commutativity of $\ast$ in homology (cf. [Ros94] pp.274-275 or [Lod98] pp.350-351). Here we give a direct proof (it means without the space $\operatorname{BGL}(R)^+$) which is essentially equivalent.

Proof. The associativity and commutativity of $\ast$ is a consequence of Lemma 5.1 and Lemma 5.2 and of the invariance by conjugation of the group homology: Indeed, let $p, q, r \in \mathbb{N}^+$ and $(g_1, \ldots, g_{p+q+r}) \in \operatorname{GL}(R)^{p+q+r}$. For all $1 \leq i \leq p + q + r$ let $A_i$ be an element in the class $g_i$. By adding 1’s on the diagonal we can suppose that the $A_i$’s are all of the same size. A representative in $\operatorname{GL}^{p+q+r}_4(R)$ of $(g_1, \ldots, g_p) \ast ((g_{p+1}, \ldots, g_{p+q}) \ast (g_{p+q+1}, \ldots, g_{p+q+r}))$ is given by

$$\sum_{\sigma \in \operatorname{Sh}_{p,q+r}} \sum_{\gamma \in \operatorname{Sh}_{p,q}} \epsilon(\sigma) \epsilon(\gamma) (a_{\sigma(\gamma^{-1}(1))}, \ldots, a_{\sigma(\gamma^{-1}(p+q+r)})$$

where $a_i$ is equal to

- $\mu_{2n}(A_i \oplus 1_n, 1_n)$ for all $1 \leq i \leq p$,
- $\mu_{2n}(1_n \oplus A_i, 1_n)$ for all $1 \leq i \leq p + q$,
- $\mu_{2n}(1_n \oplus 1_n, 1_n)$ for all $p + q + 1 \leq i \leq p + q + r$.

A representative in $\operatorname{GL}^{p+q+r}_4(R)$ of $(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q}) \ast (g_{p+q+1}, \ldots, g_{p+q+r})$ is given by

$$\sum_{\sigma \in \operatorname{Sh}_{p,q+r}} \sum_{\gamma \in \operatorname{Sh}_{p,q}} \epsilon(\sigma) \epsilon(\gamma) (b_{\sigma(\gamma^{-1}(1))}, \ldots, b_{\sigma(\gamma^{-1}(p+q+r)})$$

where $b_i$ is equal to

- $\mu_{2n}(\mu_n(A_i \oplus 1_n), 1_n)$ for all $1 \leq i \leq p$,
- $\mu_{2n}(\mu_n(1_n \oplus A_i), 1_n)$ for all $1 \leq i \leq p + q$,
- $\mu_{2n}(1_n \oplus 1_n, 1_n)$ for all $p + q + 1 \leq i \leq p + q + r$.

Lemma 5.1 and Lemma 5.2 imply that for all $n \in \mathbb{N}^+$ there are matrices $X, Y \in \operatorname{GL}_4(n)$ such that for all $A \in \operatorname{GL}_n(R)$

- $X^{-1} \mu_{2n}(A \oplus 1_n, 1_n) X = A \oplus 1_n \oplus 1_n \oplus 1_n$,
- $X^{-1} \mu_{2n}(1_n \oplus A_i, 1_n) X = 1_n \oplus 1_n \oplus A \oplus 1_n$,
- $X^{-1} \mu_{2n}(1_n \oplus 1_n, 1_n) X = 1_n \oplus 1_n \oplus 1_n \oplus A$.

Then, using the change of variables $\operatorname{Sh}_{p,q+r} \times \operatorname{Sh}_{q,r} \cong \operatorname{Sh}_{p,q} \times \operatorname{Sh}_{p,q}$, the invariance by conjugation of the group homology imply the associativity.

A representative in $\operatorname{GL}^{p+q+r}_4(R)$ of $(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q})$ is given by

$$\sum_{\sigma \in \operatorname{Sh}_{p,q}} \epsilon(\sigma)(a_{\sigma(1)} \ast \ldots \ast a_{\sigma(p+q)})$$

where $a_i$ is equal to

- $\mu_{2n}(A_i, 1_n)$ if $1 \leq i \leq p$,
- $\mu_{2n}(1_n, A_i)$ if $p + 1 \leq i \leq p + q$.

A representative in $\operatorname{GL}_{2n}(R)$ of $(g_{p+1}, \ldots, g_{p+q}) \ast (g_1, \ldots, g_p)$ is given by

$$\sum_{\gamma \in \operatorname{Sh}_{p,q}} \epsilon(\gamma)(b_{\gamma(1)} \ast \ldots \ast b_{\gamma(p+q)})$$

where $b_i$ is equal to

- $\mu_{2n}(1_n, A_i)$ if $1 \leq i \leq p$,
- $\mu_{2n}(A_i, 1_n)$ if $p + 1 \leq i \leq p + q$. 

Lemma 5.1 and Lemma 5.2 imply that for all $a \in \mathbb{N}^*$ there are matrices $X, Y \in GL_2n(R)$ such that for all $A \in GL_n(R)$
\[
X^{-1}\mu_{2n}(A, I_n)X = A \oplus I_n = Y^{-1}\mu_{2n}(I_n, A)Y,
\]
\[
X^{-1}\mu_{2n}(I_n, A)X = I_n \oplus A = Y^{-1}\mu_{2n}(A, I_n)Y.
\]

Then, using the change of variables $Sh_{p,q} \simeq Sh_{q,p}$, the invariance by conjugation of the group homology implies the commutativity.

With this product $H_*(GL(R), k)$ is an associative and commutative algebra. Moreover group homology is naturally endowed with a cocommutative coalgebra (Theorem B.11). These algebra and coalgebra structures on $H_*(GL(R), k)$ are compatible, i.e. they satisfy the Hopf relation
\[
\Delta \circ * = \epsilon \circ (\Delta \otimes \Delta)
\]

Therefore the group homology of $GL(R)$ with trivial coefficients in a field $k$ is a commutative Hopf algebra. This Hopf algebra is connected so if $k$ is a field of characteristic 0 the Hopf-Borel Theorem \[15\] implies that the Hopf algebra $(H_*(GL(R), k), \Delta, *)$ is free and cofree over its primitive part.

5.2. A coZinbiel-associative bialgebra structure on the rack homology of the general linear group. The multiplication $\mu : GL(R) \times GL(R) \to GL(R)$ being a group morphism, it is rack morphism. As a consequence the chain complex $CR_*(GL(R), k)$ computing the rack homology of $GL(R)$ is provided with a product $*$, still called the Pontryagin product, and defined by the same formula as before.

\[
* : CR_*(GL(R), k) \otimes CR_*(GL(R), k) \xrightarrow{\text{P}} CR_*(GL(R) \times GL(R), k) \xrightarrow{\text{CR}_*(p)} CR_*(GL(R), k).
\]

An explicit formula for $*$ on $CR_*(GL(R), k)$ is given by :
\[
F \cdot F' = \mu \circ (F \times F') \circ i_{p,q}
\]
where $i_{p,q}$ is the functor from $\square_{p+q}$ to $\square_p \times \square_q$ defined by $i_{p,q}((\epsilon_1, \ldots, \epsilon_{p+q})) = ((\epsilon_1, \ldots, \epsilon_p), (\epsilon_{p+1}, \ldots, \epsilon_{p+q}))$.

Under the bijection $CR_*(GL(R), k) \simeq k GL(R)^*$ the product $*$ is equal to
\[
(g_1, \ldots, g_p) \ast (g_{p+1}, \ldots, g_{p+q}) = (g_1^p, \ldots, g_p^p).
\]

**Proposition 5.4.** The product $*$ on $H_*(GL(R), k)$ is associative.

*Proof.* The proof is the same proof as in Proposition 5.3 The only thing we have to prove is the invariance by conjugation of the rack homology.

**Lemma 5.5.** Let $X$ be a rack and $a \in X$. The conjugation map $c_a = - \circ a$ induces the identity in homology.

Let $h_a : CR_*(X, k) \to CR_*(X, k)[1]$ be the map defined by $h_a(x_1, \ldots, x_n) := (a, x_1, \ldots, x_n)$. This is a chain homotopy between the identity chain map of $CR_*(X, k)$ and the chain map $CR_*(c_a)$. Therefore the homology of $X$ is invariant by conjugation by $a$.

In conclusion $H_*(GL(R), k)$ is provided with an associative algebra structure and a coZinbiel coalgebra structure (Theorem 5.4). These structures being compatible, i.e. they satisfy the semi-Hopf relation $\Delta \circ * = \epsilon \circ (\Delta \otimes \Delta)$, we proved the following theorem.

**Theorem 5.6.** $(H_*(GL(R), k), \Delta, *, *)$ is a connected coZinbiel-associative bialgebra. As a consequence this bialgebra is free and cofree over its primitive part $P$.

**Appendix A. Acyclic models**

This section is a summary of the Eilenberg-MacLane article \[15\] on acyclic models theory. This theory provides a conceptual way to prove existence and unicity (up to homotopy) of chain morphisms between chain complexes.
A.1. Representable functor. Let $A$ be a category, $M$ be a set of models (i.e. a subset of the class of objects in $A$), and $T$ be a functor from $A$ to $\mathbf{kMod}$. Let us denote by $\overline{T}$ the functor from $A$ to $\mathbf{kMod}$ defined by $\overline{T}(A) = k\{ (\phi, m) | \phi : M \rightarrow A, m \in M, \forall M \in M \}$ on objects, and $\overline{T}(f) = (f \circ \phi, m)$ on morphisms. There is a natural transformation $\Phi$ from $\overline{T}$ to $T$ defined by $\Phi_A(\phi, m) = T(\phi)(m)$. The functor $T$ is said representable if there is a natural transformation $\Psi$ from $T$ to $\overline{T}$ satisfying $\Phi \circ \Psi = \text{id}$.

**Lemma A.1.** Let $A$ be a category, $T$ and $T_1$ be functors from $A$ to $\mathbf{Mod}$, and $\xi : T \rightarrow T_1$ and $\eta : T_1 \rightarrow T$ be natural transformations such that $\xi \circ \eta = \text{id}$. If $T$ is representable then so is $T_1$.

**A.2. Representability of the evaluation functor.** Let $A$ be a category and $A$ be an object of $A$. The evaluation functor at $A$ is the functor $\text{ev}_A$ from $[C^p, \mathbf{kMod}]$ to $\mathbf{kMod}$ defined on objects by $\text{ev}_A(X) = X(A)$ and on morphisms by $\text{ev}_A(f) = f$. For all object $A \in A$, the evaluation functor $\text{ev}_A$ is representable (with set of models the set with one element $\{k\text{Hom}_A(\text{-}, A)\}$).

**Proof.** Take as set of models the set with one element $M := \{k\text{Hom}_A(\text{-}, A)\}$. Let us define a natural transformation $\Psi$ from $\text{ev}_A$ to $\overline{\text{ev}}_A$ by $\Psi_X(x) = (\phi_x, \text{id}_A)$ where $\phi_x$ is the unique natural transformation from $\text{Hom}_A(\text{-}, A)$ to $X$ satisfying $\phi_x(\text{id}_A) = x$ (Yoneda’s lemma). By definition we have $\Phi \circ \Psi$ equal to the identity, so the functor $\text{ev}_A$ is representable.

**A.3. Map and homotopy.** Let $A$ be a category, $\text{Ch}^+$ be the category of chain complexes of $\mathbb{k}$-modules and chain maps, and $K$ be a functor from $A$ to $\text{Ch}^+$. For each object $A \in A$, the functor $K$ determines a complex $K_\bullet(A)$ composed of modules $K_q(A)$ and differentials $d^q : K_q(A) \rightarrow K_{q-1}(A)$ with $d^{q-1}d^q = 0$. The modules $K_q(A)$ yield a functor $K_q$ from $A$ to $\mathbf{kMod}$ and the differentials yield natural transformations $d^q : K_q \rightarrow K_{q-1}$ with $d^{q-1}d^q = 0$.

Let $K$ and $L$ be two functors from $A$ to $\text{Ch}^+$. A map $f : K \rightarrow L$ is a family of a natural transformations $f_q : K_q \rightarrow L_q$ such that $d_q f_q = f_{q-1} d_q$. If $f_q$ is defined and satisfies this equation only for $q \leq n$, we say that $f$ is a map in dimensions $\leq n$.

Let $f, g : K \rightarrow L$ be two maps. A homotopy $D$ from $f$ to $g$ is a sequence of natural transformations $D_q : K_q \rightarrow L_{q+1}$ satisfying:

$$d^{q+1}D_q + D_{q-1}d^q = g_q - f_q.$$

If the maps $D_q$ are defined and satisfy this equality only for $q \leq n$, we say that $D$ is a homotopy in dimensions $\leq n$.

**A.4. Acyclic models theorems.** The two fundamental acyclic models theorems are the following. The first theorem concerns extension of morphisms whereas the second theorem concerns extension of homotopies between morphisms.

**Theorem A.3.** Let $K$ and $L$ be functors from a category $A$ to the category $\text{Ch}^+$, and let $f : K \rightarrow L$ be a map in dimensions $< q$. If $K_q$ is representable and if $H_{q-1}(L(M)) = 0$ for each model $M \in M$, then $f$ admits an extension to a map $K \rightarrow L$ in dimension $\leq q$.

**Theorem A.4.** Let $K$ and $L$ be functors from a category $A$ to the category $\text{Ch}^+$, let $f, g : K \rightarrow L$ be maps, and let $D : f \simeq g$ be a homotopy in dimensions $< q$. If $K_q$ is representable and if $H_q(L(M)) = 0$ for each model $M \in M$, then $D$ admits an extension to a homotopy $f \simeq g$ in dimension $\leq q$.

**Appendix B. Simplicial and Cubical sets**

This appendix is a reminder of basics of simplicial and cubical sets theory. It is based on Appendix B of [Lod98] for the simplicial set theory.
B.1. The category $\Delta$. Let $\Delta$ be the small category with set of objects $\{\Delta_n := \{0, \ldots, n\}\}_{n \in \mathbb{N}}$, and set of morphisms the set of non decreasing maps. Morphisms in $\Delta$ are generated by the two families of maps $\{\delta_i : \Delta_{n-1} \to \Delta_n\}_{0 \leq i \leq n}$ and $\{\sigma_i : \Delta_n \to \Delta_{n-1}\}_{0 \leq i \leq n}$ defined by

$$\delta_i(j) := \begin{cases} j & \text{if } j < i, \\ j + 1 & \text{if } j \geq i. \end{cases}$$

and

$$\sigma_i(j) := \begin{cases} j & \text{if } j \leq i, \\ j - 1 & \text{if } j > i. \end{cases}$$

These two families of maps satisfy relations called cosimplicial identities:

$$\delta_i \delta_j = \delta_{i+j} \delta_i \quad \forall i \leq j,$n

$$\sigma_i \sigma_j = \sigma_{i+j} \sigma_i \quad \forall i < j,$n

$$\sigma_i \delta_j = \begin{cases} \delta_{i-1} \sigma_i & \text{if } i < j, \\
\delta_i \sigma_{i-1} & \text{if } i > j. \end{cases}$$

B.2. Simplicial sets. A simplicial set is a functor $X$ from $\Delta^{op}$ to $\mathbf{Set}$. Equivalently, a simplicial set is a family of sets $\{X_n\}_{n \in \mathbb{N}}$ with two families of maps $\{d_i : X_n \to X_{n-1}\}_{0 \leq i \leq n}$ and $\{s_i : X_n \to X_{n+1}\}_{0 \leq i \leq n}$ satisfying relations called simplicial identities:

$$d_j d_i = d_{j+1} d_i \quad \forall i \leq j,$n

$$s_j s_i = s_{i-1} s_j \quad \forall i < j,$n

$$d_j s_i = \begin{cases} s_i d_{j-1} & \text{if } i < j, \\
\text{id} & \text{if } i = j, \\
s_{i-1} d_j & \text{if } i > j. \end{cases}$$

Given two simplicial sets $X$ and $Y$, a morphism of simplicial sets from $X$ to $Y$ is a natural transformation $t : X \to Y$. This is equivalent to a family of set theoretical maps $\{t_n : X_n \to Y_n\}_{n \in \mathbb{N}}$ satisfying the following commutativity relations:

$$t_{n-1} d_n^X = d_n^Y t_n,$n

$$t_n s_n^X = s_n^Y t_{n-1}.$$n

The category of simplicial sets is denoted by $\mathbf{sSet}$.

By duality a cosimplicial set is a functor $X$ from $\Delta$ to $\mathbf{Set}$. This is equivalent to the data of a family of sets $\{X_n\}_{n \in \mathbb{N}}$ with two families of maps $\{d^i : X_{n-1} \to X_n\}_{0 \leq i \leq n}$ and $\{s^i : X_n \to X_{n-1}\}_{0 \leq i \leq n}$ satisfying the cosimplicial identities.

Example B.1. $\Delta^n := \text{Hom}_\Delta(-, \Delta_n) : \Delta^{op} \to \mathbf{Set}$ for all $n \in \mathbb{N}$ is a simplicial set.

Example B.2. Let us denote by $[\Delta^n]$ the "classical" $n$-simplex in $\mathbb{R}^{n+1}$, i.e. the convex hull of the points $(0, \ldots, 1, \ldots, 0) \in \mathbb{R}^{n+1}$. We define a cosimplicial topological space $[\Delta] : \Delta \to \mathbf{Top}$ by $[\Delta]_n := [\Delta^n]$, $d^i(t_1, \ldots, t_n) = (t_1, \ldots, t_i-1, 0, t_{i+1}, \ldots, t_n)$ and $s^i(t_1, \ldots, t_n) = (t_1, \ldots, t_i, \ldots, t_n)$.

Example B.3. Let $X$ be a topological space. The simplicial set $\text{Sing}(X)$ is defined by the composition $\text{Sing}(X) := \text{Hom}_\text{Top}(-, X) \circ [\Delta]$. This construction defines a functor $\text{Sing} : \mathbf{Top} \to \mathbf{sSet}$.

B.3. Simplicial geometric realization. The geometric realization $|X|$ of a simplicial set $X$ is the coend of the functor $X \times [\Delta] : \Delta^{op} \times \Delta \to \mathbf{Top}$ defined on objects by $(X \times [\Delta])(\Delta_m, \Delta_n) := X_m \times [\Delta^n]$.

$$|X| := \int^n X_n \times [\Delta^n]$$

The topological space $|X|$ is the quotient of the topological space $\coprod_{n \in \mathbb{N}} \int^n X_n \times [\Delta^n]$ (induced by the discrete topology) by the equivalence relation

$$(X(f)x, \epsilon) \simeq (x, |\Delta(f)|) \quad (X_n \text{ provided with the discrete topology})$$

This construction induces a functor $| - | : \mathbf{sSet} \to \mathbf{Top}$ left adjoint to the functor $\text{Sing} : \mathbf{Top} \to \mathbf{sSet}$ defined in Example B.3.
B.4. Homology of simplicial sets. Let $X$ be a simplicial set. For all $n \in \mathbb{N}$ let us denote by $Q_n(X)$ the free module over $k$ generated by $X_n$, and by $C_n(X)$ the quotient of $Q_n(X)$ by the subspace generated by the images of the degeneracies $D_n(X) := \langle \text{Im}(s_i) \mid i = 0, \ldots, n \rangle$. These constructions are natural in $X$ and so induce functors

$$Q_n : sSet \to \mathcal{M}od \quad \text{and} \quad C_n : sSet \to \mathcal{M}od.$$

**Lemma B.4.** For all $n \in \mathbb{N}$ the functor $Q_n : sSet \to \mathcal{M}od$ is representable (by the set of models $\langle k, \Delta^n \rangle$).

**Proof.** Let $n \in \mathbb{N}$ be fixed and take as set of models $\mathcal{M}$ the set with one element $\langle k, \Delta^n \rangle$. By definition the functor $Q_n$ is the composition of the functor $k : \text{Set} \to \mathcal{M}od$ and the evaluation functor $\text{ev}_{\Delta^n} : cSet \to \text{Set}$

$$Q_n := k \circ \text{ev}_{\Delta^n}.$$ Let us define a natural transformation $\Psi$ from $Q_n$ to $\widetilde{Q}_n$, by the formula

$$\Psi_x : Q_n(X) \to \widetilde{Q}_n(x) : \Psi_X(x) = (\phi_x, \text{id}_{\Delta^n}),$$

where $\phi_x$ is the unique natural transformation from $\Delta^n$ to $x$ such that $(\phi_x)_n(\text{id}_{\Delta^n}) = x$ (Yoneda’s Lemma). We have $\Phi \circ \Psi = \text{id}$ so $Q_n$ is representable. \qed

Thanks to the simplicial identities the degree $-1$ graded map $d := \sum_{i=0}^n (-1)^i d_i$ satisfies the equation $d^2 = 0$. This constructions is natural in $X$ and so induces a functor

$$Q_* : cSet \to \text{Ch}^+.$$

The (simplicial) homology of $X$, denoted $H_*(X)$, is the homology of the chain complex $Q_*(X)$.

**Lemma B.5.** For all $n \in \mathbb{N}$, $H_p(\Delta^n, k) = \left\{ \begin{array}{ll} k & \text{if } p = 0, \\ 0 & \text{if } p > 0. \end{array} \right.$

**Proof.** Let $n \in \mathbb{N}$ be fixed. The simplicial homology of $\Delta^n$ is isomorphic to the singular homology of its geometric realization $|\Delta^n|$. The topological space $|\Delta^n|$ is contractible so $H_*(\Delta^n, k) = 0$. \qed

B.5. The category $\square$. Let $\square$ be the small category with set of objects the sets $\{\square_n := \{0, 1\}^n\}_{n \in \mathbb{N}}$, and set of morphisms the set of maps generated by the two families $\{\delta_i : \square_{n-1} \to \square_n\}_{i \in \{0, 1\}, 1 \leq i \leq n}$ and $\{\sigma_i : \square_n \to \square_{n-1}\}_{1 \leq i \leq n}$ where

$$\delta_i(\epsilon_1, \ldots, \epsilon_{n-1}) := (\epsilon_1, \ldots, \epsilon_{i-1}, 0, \epsilon_{i}, \ldots, \epsilon_{n-1}),$$

$$\sigma_i(\epsilon_1, \ldots, \epsilon_n) := (\epsilon_1, \ldots, \epsilon_{i-1}, 1, \epsilon_{i+1}, \ldots, \epsilon_n).$$

These two families of maps satisfy relations called cubical identities:

$$\delta_i \delta_{j+1} = \delta_{j+1} \delta_i \quad \forall i \leq j,$$

$$\sigma_i \sigma_j = \sigma_{j-1} \sigma_i \quad \forall i < j,$$

$$\sigma_i \delta_{j+1} = \left\{ \begin{array}{ll} \delta_{j+1} \sigma_i & \text{if } i < j, \\ \text{id} & \text{if } i = j, \\ \delta_j \sigma_{i-1} & \text{if } i > j. \end{array} \right.$$

Therefore each map $f \in \text{Hom}_{\square}(\square_m, \square_n)$ can be rewritten in a unique way:

$$f = \sigma_{i_1} \cdots \sigma_{i_p} \delta_{j_1,1} \cdots \delta_{j_q,1},$$

with $p + q = n - m$, $i_1 < \cdots < i_p$ and $j_1 < \cdots < j_q$. The topological space $|\Delta^n|$ is contractible so $H_*(\Delta^n, k) = 0$. \qed
B.6. Cubical sets. A cubical set is a functor \( X \) from \( \Box^{op} \) to \( \text{Set} \). Equivalently, a cubical set is a family of sets \( \{ X_n \}_{n \in \mathbb{N}} \) with two families of maps \( \{ d_{i}^{s} : X_{n} \rightarrow X_{n-1} \}_{i \in \{0,1\}, 1 \leq i \leq n} \) and \( \{ s_{i} : X_{n-1} \rightarrow X_{n} \}_{1 \leq i \leq n} \) satisfying relations called cubical identities:

\[
d_{j,\omega}d_{i,\varepsilon} = d_{i,\varepsilon}d_{j,\omega} \quad \forall i \leq j;
\]

\[
s_{j}s_{i} = s_{i-1}s_{j} \quad \forall i < j;
\]

\[
d_{j,\varepsilon}s_{i} = \begin{cases} 
    s_{i}d_{j,\varepsilon} & \text{if } i < j, \\
    \text{id} & \text{if } i = j, \\
    s_{i-1}d_{j,\varepsilon} & \text{if } i > j.
\end{cases}
\]

Given two cubical sets \( X \) and \( Y \), a morphism of cubical sets from \( X \) to \( Y \) is a natural transformation \( t : X \rightarrow Y \). This is equivalent to a family of set theoretical maps \( \{ t_{n} : X_{n} \rightarrow Y_{n} \}_{n \in \mathbb{N}} \) satisfying the following commutativity relations:

\[
t_{n-1}d_{i}^{X} = d_{i}^{Y}t_{n},
\]

\[
t_{n}s_{i}^{X} = s_{i}^{Y}t_{n-1}.
\]

The category of cubical sets is denoted by \( \text{cSet} \).

By duality a cocubical set is a functor \( X \) from \( \Box \) to \( \text{Set} \). This is equivalent to the data of a family of sets \( \{ X_{n} \}_{n \in \mathbb{N}} \) with two families of maps \( \{ d_{i}^{s} : X_{n} \rightarrow X_{n-1} \}_{i \in \{0,1\}, 1 \leq i \leq n} \) and \( \{ s_{i} : X_{n-1} \rightarrow X_{n} \}_{1 \leq i \leq n} \) satisfying the cocubical identities.

Example B.6. \( \Box^{n} := \text{Hom}_{\Box}(\cdot, \Box_{n}) : \Box^{op} \rightarrow \text{Set} \) for all \( n \in \mathbb{N} \).

Example B.7. Let us denote by \( |\Box| \) the "classical" \( n \)-cube in \( \mathbb{R}^{n} \), i.e., the topological space \([0,1]^{n}\). We define a cocubical topological space \( |\Box| : \Box \rightarrow \text{Top} \) by \( |\Box|_{n} := |\Box^{n}| \), \( d_{i}^{s} : (t_{1}, \ldots, t_{n}) \rightarrow (t_{1}, \ldots, t_{i-1}, \epsilon, t_{i}, \ldots, t_{n}) \) and \( s_{i} : (t_{1}, \ldots, t_{n}) \rightarrow (t_{1}, \ldots, t_{i}, \ldots, t_{n}) \).

Example B.8. Let \( X \) be a topological space. The cubical set \( \text{Cub}(X) \) is defined by the composition \( \text{Cub}(X)_{n} := \text{Hom}_{\text{Top}}(\cdot, X) \circ |\Box| \). This construction defines a functor \( \text{Cub} : \text{Top} \rightarrow \text{cSet} \).

B.7. Cubical geometric realization. The geometric realization \( |X| \) of a cubical set \( X \) is the coend of the functor \( X \times |\Box| : \Box^{op} \times \Box \rightarrow \text{Top} \) defined on objects by \((X \times |\Box|)(\Box_{m}, \Box_{n}) := X_{m} \times |\Box^{n}| \).

\( |X| := \int\int_{n \in \mathbb{N}} X_{n} \times |\Box^{n}| \)

The topological space \( |X| \) is the quotient of the topological space \( \coprod_{n \in \mathbb{N}} X_{n} \times |\Box^{n}| \) (\( X_{n} \) provided with the discrete topology) by the equivalence relation

\( (X(f)x, \varepsilon) \simeq (x, |\Box|(f)(\varepsilon)) \).

This construction induces a functor \( - \circ |\Box| : \text{cSet} \rightarrow \text{Top} \) left adjoint to the functor \( \text{Cub} : \text{Top} \rightarrow \text{cSet} \) defined in Example B.6.

B.8. Homology of cubical sets. Let \( X \) be a cubical set. For all \( n \in \mathbb{N} \) let us denote by \( Q_{n}(X) \) the free module over \( \mathbb{k} \) generated by \( X_{n} \), and by \( C_{n}(X) \) the quotient of \( Q_{n}(X) \) by the subspace generated by the images of the degeneracies \( D_{n}(X) := \mathbb{k}(\text{im}(s_{i})) \mid i = 1, \ldots, n \). These constructions are natural in \( X \) and so induce functors

\( Q_{n} : \text{cSet} \rightarrow \mathbb{k}\text{Mod} \) and \( C_{n} : \text{cSet} \rightarrow \mathbb{k}\text{Mod} \).

Proposition B.9. The functors \( Q_{n} \) and \( C_{n} \) are representable by \( \mathbb{k}.\Box^{n} \).

Proof. Let \( n \in \mathbb{N} \) be fixed and take as set of models \( \mathcal{M} \) the set with one element \( \{ \mathbb{k}.\Box^{n} \} \). By definition the functor \( Q_{n} \) is the composition of the functor \( \mathbb{k} \circ |\Box| : \text{Set} \rightarrow \mathbb{k}\text{Mod} \) and the evaluation functor \( \text{ev}_{\Box_{n}} : \text{cSet} \rightarrow \text{Set} \)

\( Q_{n} := \mathbb{k} \circ \text{ev}_{\Box_{n}} \).

Let us define a natural transformation \( \Psi \) from \( Q_{n} \) to \( Q_{n} \), by the formula

\( \Psi_{X} : Q_{n}(X) \rightarrow \tilde{Q}_{n}(X) ; \Psi_{X}(x) = (\phi_{x}, \text{id}_{\tilde{X}}) \).
where $\phi_\ast$ is the unique natural transformation from $\Box^n$ to $X$ such that $(\phi_\ast)_n(\text{id}_{C_n}) = x$ (Yoneda’s Lemma). We have $\Phi \circ \Psi = \text{id}$ so $Q_\ast$ is representable.

The representability of $C_\ast$ is a consequence of Lemma A.1. Indeed, let $\xi : Q_\ast \to C_\ast$ be the natural transformation defined by passing to the quotient, and let $\eta : C_\ast \to Q_\ast$ be the natural transformation defined by

$$\eta_\ast := (\text{id} - s_1 d_{1,0}) \cdots (\text{id} - s_n d_{n,0}).$$

Thanks to the cubical identities this map sends $D_0(X)$ to 0 and so is well defined. Moreover $\xi \circ \eta = \text{id}$ then by Lemma A.1 the functor $C_\ast$ is representable.

Thanks to the cubical identities the degree $-1$ graded map $d := \sum^n_{i=1} (-1)^{i+1}(d_{i,1} - d_{i,0})$ satisfies the equation $d^2 = 0$ and sends $D_0(X)$ into $D_{n-1}(X)$. These constructions are natural in $X$ and so induce functors

$$Q_\ast : \text{cSet} \to \text{Ch}^+ \quad \text{and} \quad C_\ast : \text{cSet} \to \text{Ch}^+.$$ 

The unnormalized (cubical) homology of $X$, denoted $H^\ast_n(X)$, is the homology of the chain complex $Q_\ast(X)$. The (cubical) homology of $X$, denoted $H_\ast(X)$, is the homology of the chain complex $C_\ast(X)$.

**Lemma B.10.** For all $n \in \mathbb{N}$, $H_0(\Box^n, k) = \begin{cases} k & \text{if } p = 0, \\ 0 & \text{if } p > 0. \end{cases}$

**Proof.** Let $n \in \mathbb{N}$ be fixed. The cubical homology of $\Box^n$ is isomorphic to the singular homology of its geometric realization $[0, 1]^n$. The topological space $[0, 1]^n$ is contractible so $H_\ast(\Box^n, k) = 0$.

**B.9. A differential graded coassociative coalgebra structure on the chain complex of a cubical set.** Let $X$ be a cubical set. Let us define a degree 0 map $\Delta(X)$ from $C_\ast(X)$ to $C_\ast(X) \otimes C_\ast(X)$ by the following formula :

$$\Delta(X)_n(x) := \bigoplus_{p+q=n} \sum_{\sigma \in \text{Sh}_{p,q}} \epsilon(\sigma) (d_{\sigma(p+1),0} \cdots d_{\sigma(p+q),0}) (x) \otimes (d_{\sigma(1),1} \cdots d_{\sigma(p),1}(x))$$

for all $x \in X_n$, $n \geq 1$ and $\Delta(X)_0(x) = x \otimes x$ for $x \in X_0$. With enough stamina it is possible to check that this formula defines a chain complex morphism. A more conceptual way to prove that such a chain morphism exists and is unique up to homotopy is to use the method of acyclic models : Indeed, define $\Delta$ in dimension 0 by the previous formula. It induces a map between homology groups $\Delta_0 : H_0(X, k) \to H_0(X, k)$. By induction we can extend this map to a unique up to homotopy morphism of chain complexes using the theorem of acyclic models. Indeed, by Proposition B.9 the functor $C_\ast$ is representable by $\Box^n$ for all $n \in \mathbb{N}$, and by Lemma B.10 the homology groups $H_p(C_\ast(\Box^n) \otimes C_\ast(\Box^n))$ vanish for all $p, n \in \mathbb{N}$. Then by the theorem of acyclic models [A.3] and [A.4] there exists a homotopy unique chain map $\Delta$ extending $\Delta_0$.

**Theorem B.11.** Let $X$ be a cubical set. Then $(C_\ast(X, k), \Delta)$ is an homotopy coassociative and homotopy cocommutative coalgebra (in the category of chain complexes).

**Proof.** The maps $(\text{id} \otimes \Delta) \circ \Delta$ and $(\Delta \otimes \text{id}) \circ \Delta$ are two maps from $C_\ast$ to $C_\ast \otimes C_\ast \otimes C_\ast$ which coincide in dimension 0. Therefore by the theorem of acyclic models [A.4] these two maps are homotopic.

The maps $\Delta$ and $\tau \circ \Delta$ are two maps from $C_\ast$ to $C_\ast \otimes C_\ast$, which coincide in dimension 0. Therefore by the theorem of acyclic models [A.4] these two maps are homotopic.

**Corollary B.12.** Let $X$ be a cubical set and $k$ be a field. Then $(H_\ast(X, k), \Delta)$ is a coassociative and cocommutative coalgebra (in the category of graded vector space).
