Pathology and Biomechanics of the Human Achilles Tendon

Abstract
Biomechanical engineering has achieved much progress in an attempt to improve and recover impaired functions of tissues and organs. Although many studies have been done, progress for biomechanical-engineered Achilles tendon has been slow due to their complex structures and mechanical properties. In this review, the Achilles tendon anatomical structure, mechanical properties, and risk factors of rupture have been discussed. This is a considerably huge amount work that needs to be carried out; as such, future direction in tendon biomechanical engineering is proposed in hope that this review will give information on future tendon biomechanical engineering.

Keywords: Achilles tendon; Mechanical properties; Risk factors

Introduction
The tendinous portions of the gastrocnemius and soleus muscles merge to form the Achilles tendon [1]. Achilles tendinopathy, including tendon rupture, occur at a rate of about 250,000 per year in the US alone [2,3]. The incidences of Achilles tendon ruptures have significantly increased over the last 20 years [2,4], achieving, within the tendon disease, an incidence between 6 and 18% [5-7]. The Achilles tendon rupture etiology remains poorly known [8,9] and it is essentially based on two main theories: the degenerative theory and the mechanical theory.

In humans, the Achilles tendon is the thickest and strongest tendon that sustains some of the largest tensile loads in the body [10]. Dysfunction and injuries are commonly seen in the Achilles tendon. The fibrous matrix of tendons mainly consists of collagen and a small amount of elastin, which are produced and maintained by tenoblasts and tenocytes [11]. Tendon consists primarily of collagen (70-80% of the tissue's dry weight) and less than 5% tenocytes and tendoblasts [12]. These insoluble elements are embedded within a hydrated environment containing ground substance of proteoglycans, glycosaminoglycan (GAG) and some other small molecules [13].

The mechanism of tendinopathy and rupture is complex and thought to be influenced by tendon geometry, material-strength, sex, disease and genetics. Achilles tendon rupture is typically reported to occur at 2-6 cm above the insertion to the calcaneus bone, in a region that is hypovascular [14]. It is not understood why this region receives poor blood supply and is prone to rupture.

Research on Achilles tendon has been going on for some time, with the hope of overcoming the present problems. Usually, mechanical and structural information about Achilles tendon are necessary to facilitate studies in biomechanical, tissue engineering, surgical and rehabilitation fields.

Methods
In this review, we try to find mechanical properties in vivo and in vitro because of calculating the human Achilles tendon's properties passively and actively. In addition, identifying of structure and risk factors of Achill tendon can provide appropriate information to scientists.

Results
Mechanical properties
The functional and mechanical behavior of human skeletal muscle are in many ways unknown during natural and artificial locomotion. To gain more insight into these questions a method was developed to record directly in vivo and in vitro forces from the human Achilles tendon. The Table 1 shows the mechanical properties of the Achill tendon.

Structure of fibrous matrix
The Table 2 shows the biomechanical constituents of the Achill tendon. The recent study [15] showed that while the majority of the Achilles tendon is supplied by the posterior tibial artery from its medial edge, the peroneal artery provides supply to the middle section of the tendon laterally. The midsection of the Achilles tendon was found to be hypovascular in all cases of the study.

Risk factors
The Achilles tendon is the most frequently ruptured tendon. The Table 3 shows the risk factors of the Achilles tendon rupture. The ruptured Achilles tendons show various forms of degenerative tendinopathy. It is not known why there are differences in types and amounts of degeneration between individual tendons, although there is evidence suggesting that decreased arterial
blood flow, resulting local hypoxia and impaired nutrition and metabolic activity are the key factors. A sedentary lifestyle has been proposed as the main reason for poor circulation in the tendon.

Table 1: Summary of structural and mechanical properties of human Achilles tendon.

Discussion

This research investigated the properties of human Achilles tendon materially, mechanically, anatomically, and pathologically. The human Achilles tendon is the thickest and strongest tendon among all of human’s tendons [10]. The incidence of total Achilles tendon rupture has increased during the past decade. The rise is more prominent among men and in the context of sports-related injuries. Majority of ruptures occurs in recreational involved in sports requiring bursts of jumping, pivoting and running (Table 3). Lack of a universal, consistent protocol for passive and active evaluation of Achilles tendon has prevented any direct comparison of results. This paper makes it possible to analyze and compare the results and seek prognostic factors related to the results.

Table 3: Summary of Achilles tendon rupture (ATR) risk factors.

| Cause                      | Explanation                      | Range     | Reference |
|----------------------------|----------------------------------|-----------|-----------|
| Middle-aged                | Decreasing blood flow rate       | 30 - 40 y | 31,36,41  |
|                            | Increasing stiffness             | 40 - 50 y | 40        |
