A new solvable N-body model of goldfish type is identified. Its Newtonian equations of motion read as follows:

\[ \ddot{z}_n = -6\dot{z}_n z_n^3 - 4z_n^2 + \frac{4}{3}(\dot{z}_n + 2z_n^2) \sum_{\ell=1, \ell \neq n}^{N} \left( \frac{\dot{z}_n + 2z_n^2}{z_n - z_\ell} \right), \quad n = 1, \ldots, N, \]

where \( z_n = z_n(t) \) are the \( N \) dependent variables (with \( N \) an arbitrary positive integer), \( t \) is the independent variable (“time”) and the dots indicate time-differentiations. Its isochronous variant is also obtained and discussed. Other new solvable models of goldfish type characterize the behavior of these systems in the immediate neighborhood of their equilibria.

Keywords: Integrable dynamical systems; solvable dynamical systems; integrable Newtonian many-body problems; solvable Newtonian many-body problems; isochronous dynamical systems.

Mathematical Subject Classification: 70F10, 70H99, 37J35, 37K10

1. Introduction

The basic goldfish dynamical system [1] — also interpretable as the simplest dynamical system belonging to the integrable Ruijsenaars–Schneider class [9] — is defined by the following Newtonian equations of motion:

\[ \ddot{z}_n = 2 \sum_{\ell=1, \ell \neq n}^{N} \left( \frac{\dot{z}_n \dot{z}_\ell}{z_n - z_\ell} \right), \quad n = 1, \ldots, N. \] (1a)

Notation 1.1. Here and hereafter \( N \) is an arbitrary positive integer, indices such as \( n, \ell \) run from 1 to \( N \) unless otherwise indicated (but for the convenience of the reader we generally specify below the range of the indices), \( t \) (“time”) is the independent (real) variable, the
$N$ coordinates $z_n$ are the dependent variables, $z_n \equiv z_n(t)$, and superimposed dots denote time-differentiations.

It is generally convenient to assume that the dependent variables $z_n$ are complex numbers, identifying the positions of $N$ points moving in the complex $z$-plane. By introducing the real and imaginary parts of the coordinates $z_n = x_n + iy_n$ and correspondingly the real two-vectors $\vec{r}_n = (x_n, y_n)$, to the motions in the complex $z$-plane of points identified by the complex coordinates $z_n$ there correspond the motions of real points whose positions in the horizontal plane are identified by the real two-vectors $\vec{r}_n$; this provides an added justification for referring to dynamical systems of goldfish type as many-body problems, as we occasionally do (also in the title of this paper). Moreover, it is often possible to write the corresponding equations of motion in covariant form. It would be possible to do so also for the many-body models considered in this paper, but we refrain from doing so; readers interested in pursuing this transformation are referred to Chap. 4 (entitled “Solv-able and/or integrable many-body problems in the plane, obtained by complexification”) of [2].

For an explanation of the origin of the term “goldfish” see [3; 4, p. 7].

A remarkable property of the many-body problem (1a) is its solvability, given by this neat prescription: the $N$ values of the $N$ dependent variables at time $t$, $z_n(t)$, are the $N$ roots of the following algebraic equation for the unknown $z$,

$$\sum_{n=1}^{N} \frac{\dot{z}_n(0)}{z - z_n(0)} = \frac{1}{t},$$

where $\dot{z}_n(0)$ respectively $z_n(0)$ are the initial velocities respectively positions of the $N$ point-like moving particles [1, 4, 2, 3]. Note that this equation, after multiplication by the $N$-degree polynomial $\prod_{m=1}^{N} |z - z_m(0)|$, becomes a (time-dependent) polynomial equation of degree $N$ for the unknown $z$, demonstrating thereby that it indeed yields $N$ values $z_n \equiv z_n(t)$ as its solutions.

Over time several more $N$-body models “of goldfish type” have been identified, their signature being provided by the presence in the right-hand side of the Newtonian equations (“accelerations equal forces”) characterizing them — in addition to other contributions — of a term identical to that appearing in the right-hand side of (1a). All these models are solvable, meaning that their initial-value problem can be solved by algebraic operations, generally by finding the $N$ eigenvalues of an explicitly known time-dependent $N \times N$ matrix, or equivalently, as in the case described above, see (1b), by finding the $N$ roots of a time-dependent polynomial of degree $N$; see [2] and especially [4, Sec. 4.2.2]. Recent additions to this catalog of solvable many-body problems of goldfish type are reported in [5–7]. Purpose and scope of the present paper is to provide one more — indeed, see below, a few — new solvable many-body models of goldfish type. It is quite possible that additional new examples will be found over time: we consider such a search worthwhile, and any such finding remarkable.

The basic new model, and its solution, are described in the following Sec. 2, firstly in its nonisochronous version, and then in its (more general) isochronous variant. Other versions of these models are also obtained. The equilibrium configurations of these models are also reported, and new, nontrivial, solvable models of goldfish type characterizing the behavior.
New Solvable Many-Body Model of Goldfish Type

in the immediate neighborhood of these equilibria are exhibited. Proofs are then provided in Sec. 3.

2. Results

In this section, we report the main results, firstly for the new model and then for its isochronous variant.

2.1. The nonisochronous model

The new model is defined by the following Newtonian equations of motion:

\[ \ddot{z}_n = \frac{3}{2} \dot{z}_n^2 + 2z_n^3 + (\dot{z}_n + 2z_n^2) \sum_{\ell=1,\ell \neq n}^{N} \left[ (\dot{z}_\ell + 2z_\ell^2) \left( \frac{3}{2z_\ell} - \frac{2}{z_n - z_\ell} \right) \right], \quad n = 1, \ldots, N, \quad (2a) \]

or, equivalently,

\[ \ddot{z}_n = -6 \dot{z}_n z_n - 4z_n^3 + \frac{3}{2} (\dot{z}_n + 2z_n^2) \eta + 2 \sum_{\ell=1,\ell \neq n}^{N} \left[ \frac{\dot{z}_n + 2z_n^2}{z_n - z_\ell} \right], \quad n = 1, \ldots, N, \quad (2b) \]

where

\[ \eta = \sum_{k=1}^{N} (\dot{z}_k + 2z_k). \quad (2c) \]

The solution of the corresponding initial-value problem is given by the following

Proposition 2.1. The \( N \) coordinates \( z_n(t) \) are the \( N \) eigenvalues of the following \( N \times N \) matrix \( U(t) \),

\[ U(t) = [1 - tY(0)]^{-1} Z(0) \cdot [1 - tY(0) - t^2 Z(0)]^{-1} Z(0)^{-1} \quad (3a) \]

with the two \( N \times N \) matrices \( Z(0) \) and \( Y(0) \) expressed componentwise as follows in terms of the initial data \( z_n(0), \dot{z}_n(0) \):

\[ \begin{align*}
Z(0) &= \text{diag}[z_n(0)], \quad Z_{nm}(0) = \delta_{nm} z_n(0), \quad n, m = 1, \ldots, N, \\
Y_{nm}(0) &= \delta_{nm} \frac{\dot{z}_n(0)}{2z_n(0)} + (1 - \delta_{nm}) \left[ \frac{\dot{z}_n(0)}{2z_n(0)} + 2z_n(0) \right] \left[ \frac{\dot{z}_m(0)}{z_m(0)} + 2z_m(0) \right]^{1/2}, \quad n, m = 1, \ldots, N. \quad (3b) \end{align*} \]

Here and hereafter \( \delta_{nm} \) is the standard Kronecker symbol, \( \delta_{nm} = 1 \) if \( n = m, \delta_{nm} = 0 \) if \( n \neq m \).

It is thus seen that the solution of the initial-value problem for the Newtonian equations of motion (2) characterizing our new \( N \)-body problem of goldfish type is achievable by purely algebraic operations, namely by finding the \( N \) eigenvalues \( z_n(t) \) of the \( N \times N \) matrix

\[ \begin{align*}
\end{align*} \]
F. Calogero

$U(t)$ given, in terms of the $2N$ initial values $z_m(0), \dot{z}_m(0), m = 1, \ldots, N,$ and of the time $t,$ by the explicit (if complicated) formulas (3).

**Remark 2.1.** For $N = 1,$ the system (2) reduces to the single equation of motion (with $z_1(t) = z(t)$)

\[
\ddot{z} = \frac{3}{2} \frac{\dot{z}^2}{z} + 2z^3
\]

and the solution of the corresponding initial-value problem reads

\[
z(t) = \frac{z(0)}{1 - 2zt + [z^2 - \dot{z}^2(0)]t^2}, \quad v = \frac{\dot{z}(0)}{2z(0)}.
\]

Clearly in this case the only equilibrium configuration is $z = \dot{z} = 0.$

**Remark 2.2.** The asymptotic behavior as $t \to \infty$ of the $N \times N$ matrix $U(t),$ see (3), reads

\[
U(t) = -t^{-2}\left[Z(0) - Y(0)[Z(0)]^{-1}Y(0)\right]^{-1} + O(t^{-1}),
\]

entailing that all the coordinates $z_n(t)$ vanish asymptotically proportionally to $t^{-2}.$

**Remark 2.3.** It is easily seen, by summing the $N$ ODEs (2b) divided by $z_n,$ by using the definition (2c) of $\eta,$ by taking advantage of the possibility to exchange the role of the two dummy indices $n$ and $\ell$ when both are summed upon, and by utilizing the identity

\[
\frac{1}{z_n - z_\ell} \left( \frac{1}{z_n} - \frac{1}{z_\ell} \right) = -\frac{1}{z_n z_\ell}
\]

that one gets the ODE

\[
\ddot{\eta} = \frac{\dot{\eta}^2}{2}
\]

yielding

\[
\eta(t) = \frac{2\eta(0)}{1 - \eta(0)t} = -\frac{2}{t + t_0},
\]

of course with

\[
t_0 = -\frac{2}{\eta(0)} = -2 \left\{ \sum_{k=1}^N \frac{\dot{z}_k(0)}{z_k(0)} + 2z_k(0) \right\}^{-1}.
\]

Hence an equivalent, nonautonomous, version of the many-body model (2b) obtains by replacing in these equations of motion the expression (2c) of the collective coordinate $\eta$ in terms of $z_n$ and $\dot{z}_n$ with its explicit time-dependent expression (8).

**Proposition 2.2.** For this many-body model with $N \geq 2$ the equilibrium configuration — defined of course up to permutations of the $N$ coordinates — features $N - 2$ vanishing coordinates and the remaining 2 having equal and opposite values, say $z_n = \dot{z}_n = 0, n = 1, \ldots, N - 2$ and $z_N = \bar{z}, z_{N-1} = -\bar{z}$ with $\bar{z}$ an arbitrary constant (possibly also vanishing); of course to the extent the last term in the right-hand side of (2a) is assigned a vanishing value when $z_n = \dot{z}_n = 0$ and $z_\ell = \dot{z}_\ell = 0.$
The behavior of the nonisochronous system (2b) in the immediate neighborhood of its equilibrium configuration is described by an, of course solvable, dynamical system of goldfish type. This is obtained from (2b) by setting, say,

\[ z_{N-1}(t) = \bar{z} + \varepsilon y_1(t); \quad z_N(t) = -\bar{z} + \varepsilon y_2(t); \]
\[ z_n(t) = \varepsilon x_n(t), \quad n = 1, \ldots, N_0 = N - 2, \]

with \( \bar{z} \) an arbitrary constant and \( \varepsilon \) infinitesimal. Here we assume the constant \( \bar{z} \) to be finite (nonvanishing): the analogous treatments of the cases when \( \bar{z} \) vanishes or is itself of order \( \varepsilon \) are left for the alert reader. The relevant equations are conveniently written as follows:

\[ \ddot{f} = \frac{3}{2} \chi \dot{f} + 8 \varepsilon^2 f + 6 \varepsilon \chi g + 12 \varepsilon^2 \varphi, \]  \( (10a) \)
\[ \ddot{g} = \frac{3}{2} \chi \dot{g} - 4 \varepsilon^2 g - 2 \varepsilon \dot{f} + 6 \varepsilon \chi f + 8 \varepsilon \dot{\varphi}, \]  \( (10b) \)
\[ \ddot{x}_n = \frac{3}{2} \chi \dot{x}_n + 2 \sum_{\ell=1, \ell \neq n}^{N_0} \left( \frac{\dot{x}_n \dot{x}_\ell}{x_n - x_\ell} \right), \quad n = 1, \ldots, N_0, \]  \( (10c) \)

where

\[ f = y_1 + y_2, \quad g = y_1 - y_2; \quad \varphi = \sum_{n=1}^{N_0} (x_n), \quad \chi = \sum_{n=1}^{N_0} \left( \frac{x_n}{x_n - x_\ell} \right). \]  \( (10d) \)

Note that the system (10c) with the collective coordinate \( \chi \) defined by (10d) and \( N_0 \) an arbitrary positive integer is an (of course solvable) dynamical system of goldfish type (not new, see [4, Eq. (4.135)] with \( \alpha = b = 0 \) and \( a = 1/2 \)).

**Remark 2.4.** It is easily seen — as in Remark 2.3 — that the system (10c) implies for the collective coordinate \( \chi \), see (10d), the ODE

\[ \dot{\chi} = \frac{\chi^2}{2} \]  \( (11) \)

yielding

\[ \chi(t) = \frac{2 \chi(0)}{2 - \chi(0)t} = \frac{2}{t + t}, \]  \( (12a) \)

of course with

\[ \bar{t} = \frac{2}{\chi(0)} = -2 \left( \sum_{n=1}^{N_0} \frac{\dot{x}_n(0)}{x_n(0)} \right)^{-1}. \]  \( (12b) \)

By inserting this expression, (12), of \( \chi \) in (10c) one obtains an equivalent, nonautonomous, version of this dynamical system of goldfish type.

Likewise, by summing the \( N_0 \) ODEs (10c) and using the definition of \( \varphi \), see (10d), one gets the ODE

\[ \ddot{\varphi} = \frac{3}{2} \chi \dot{\varphi}; \]  \( (13) \)
which, using (12), is easily integrated, yielding

\[ \varphi(t) = \varphi(0) + \frac{\varphi(0)}{\chi(0)} \left( 1 - \frac{4}{2 - \chi(0)t^2} \right) \]

Hence by inserting these explicit expressions, (12) and (14), of the collective quantities \( \chi(t) \) and \( \varphi(t) \) in the two linear ODEs (10a) and (10b) — with \( \chi(0) \) or \( \varphi(0) \) now playing the role of arbitrary constants — one obtains a nonautonomous solvable system of two linear second-order ODEs; or equivalently — by solving (10a) for \( g \) and inserting the resulting expression of \( g \) in (10b) — one obtains the following fourth-order linear nonautonomous single ODE for the dependent variable \( f(t) \):

\[ \ddot{f} = \frac{8}{t + t} f + 4 \left( \frac{3}{t + t} \right) \dot{f} + f + \frac{8}{2} \left( \frac{64}{t + t} \right) f + \psi h, \quad (15a) \]

with

\[ h(t) = \left( 48 z + 9 \frac{4}{4(t + t)} \right) \varphi(0) \]

\[ + \left( 24 v + 9 \frac{1}{24 v^2} \right) \frac{1}{(t + t)^2} - \frac{273}{8} \frac{t^2}{(t + t)^2} \dot{\varphi}(0), \quad (15b) \]

where \( z, f, \varphi(0) \) and \( \dot{\varphi}(0) \) are 4 arbitrary constants. The possibility is far from trivial — yet implied by the above developments — to obtain by algebraic operations the solution of the initial-value problem for this ODE, (15), corresponding to an arbitrary assignment of the 4 initial data \( f(0), \dot{f}(0), \varphi(0), \dot{\varphi}(0) \), or equivalently of the initial-value problem for the system of two coupled ODEs (10a) and (10b) with (12) and (14) corresponding to an arbitrary assignment of the 4 initial data \( f(0), \dot{f}(0), \varphi(0), \dot{\varphi}(0) \).

It is now convenient to introduce the (monic) polynomial \( \psi(z, t) \) that features the \( N \) coordinates \( z_n(t), n = 1, \ldots, N \), as its \( N \) zeros and the \( N \) quantities \( c_m(t), m = 1, \ldots, N \), as its \( N \) coefficients,

\[ \psi(z, t) = \prod_{n=1}^{N} (z - z_n(t)) = z^N + \sum_{m=0}^{N} c_m(t) z^{N-m}. \quad (16a) \]

These formulas entail

\[ \sum_{n=1}^{N} z_n = -c_1 \quad (16b) \]

and (see, if need be, [4, Eq. (A.11)])

\[ \sum_{n=1}^{N} \frac{z_{n}}{z_{n}} = \frac{c_N}{c_N} \quad (16c) \]

The definition (16a) implies a one-to-one (nonlinear) relation among the unordered set of the \( N \) zeros \( z_n(t) \) and the ordered set of the \( N \) coefficients \( c_m(t) \). Whenever the \( N \) coordinates \( z_n(t) \) evolve according to a solvable dynamical system, the corresponding evolution of the \( N \)
coefficients \( c_m(t) \) is as well solvable, since the relation among the \( N \) coordinates \( z_n(t) \) and the \( N \) coefficients \( c_m(t) \) entailed by the relation \((16a)\) with \((16b)\) and \((16c)\) is obviously algebraic. It is moreover well known \([1, 2, 4]\) that when the \( N \) coordinates \( z_n(t) \) evolve according to a dynamical system of goldfish type, the corresponding dynamical system satisfied by the coordinates \( c_m(t) \) is generally rather neat hence worth display (and its derivation amounts to a standard computation, facilitated by the identities reported in the \([4, \text{Appendix A}]\)). We therefore now report, without detailing its derivation, the solvable dynamical system satisfied by the \( N \) coefficients \( c_m(t) \) which corresponds to the solvable dynamical system of goldfish type \((2)\):

\[
\begin{align*}
\dot{c}_m &= \left( \frac{3c_N}{2c_N} + c_1 \right) c_m + \left( \frac{3c_N}{c_N} - 2c^2 - 2c_1 \right) c_m \\
&- \left[ 3(m + 1)c_N^2 + 2(m - 1)c_1 \right] c_{m+1} + 2(2m + 1)c_{m+1} \\
&+ 4m(m + 2)c_{m+2} = 0, \quad c_{N+1} = c_{N+2} = 0, \quad m = 1, \ldots, N. \tag{17}
\end{align*}
\]

The initial data for this solvable dynamical system are of course the \( 2N \) numbers \( c_m(0), c_m(0), m = 1, \ldots, N \).

For \( N = 1 \) this system reduces of course to the single ODE \((4a)\) (with \( c_1(t) = -z(t) \)).

And let us also display this solvable nonlinear system for \( N = 2 \):

\[
\begin{align*}
\dot{c}_1 &= \frac{3\dot{c}_1}{2c_2} + \frac{3\dot{c}_2c_1^2}{c_2} - 3c_1c_1 - 2c_1^2 = 0, \tag{18a} \\
\dot{c}_2 &= \frac{3\dot{c}_2}{2c_2} + 2\dot{c}_1c_1 - 2c_1c_2 - 2c_1^2c_2 = 0. \tag{18b}
\end{align*}
\]

**Remark 2.5.** An equivalent, but nonautonomous, version of the equations of motion \((17)\) obtains via the relation (implied by \((2c)\) and \((8)\) with \((16b)\) and \((16c)\))

\[
\frac{\dot{c}_N(t)}{c_N(t)} = 2c_1(t) - \frac{2}{t + t_0}, \tag{19a}
\]

of course now with

\[
t_0 = -\frac{1}{2} \left[ \frac{c_N(0)}{c_N(0)} - 2c_1(0) \right]^{-1}. \tag{19b}
\]

For instance the diligent reader will verify that, for \( N = 2 \), the insertion of the expression \((19a)\) of \( \dot{c}_2/c_2 \) in \((18b)\) yields an identity, while its insertion in \((18a)\) yields the second-order nonautonomous ODE

\[
\dot{c}_1 = 6c_1c_1 - 4c_1^2 - \frac{3(c_1 - 2c_1^2)}{t + t_0}. \tag{20a}
\]

In this ODE \( t_0 \) has become an arbitrary parameter, in fact quite irrelevant amounting simply to a shift of the independent variable \( t \). It is easily seen that two special solutions of this nonlinear nonautonomous ODE read

\[
c_1(t) = \pm \frac{1}{2(t + t_0)}. \tag{20b}
\]
Again, less trivial is the possibility, entailed by the above developments, to obtain by elementary algebraic operations the solution of the initial-value problem for the ODE (20a) corresponding to an arbitrary assignment of the 2 initial data \( c_1(0) \) and \( \dot{c}_1(0) \).

### 2.2. The isochronous model

The *isochronous model* is obtained from the preceding one via the following standard trick (see, for instance [4, Sec. 2.1]). Let

\[
\tau \equiv \tau(t) = \exp(i\omega t) - \frac{1}{i\omega}.
\] (21a)

Here and throughout \( \omega \) is an arbitrary positive constant, with the dimension of inverse time, to which we associate the period

\[
T = \frac{2\pi}{\omega}.
\] (21b)

Introduce then the new dependent variables \( \tilde{z}_n(t) \) by setting

\[
\tilde{z}_n(t) = \exp(i\omega t) z_n(\tau), \quad z_n(t) = \exp(-i\omega t) \tilde{z}_n(\tau),
\] (22a)

so that

\[
\ddot{\tilde{z}}_n - i\omega \dot{\tilde{z}}_n = \exp(2i\omega t) z_n'(\tau), \quad \dot{z}_n'(\tau) = \exp(-2i\omega t)(\ddot{\tilde{z}}_n - i\omega \dot{\tilde{z}}_n),
\] (22b)

and

\[
\ddot{z}_n - 3i\omega \dot{z}_n - 2\omega^2 \ddot{\tilde{z}}_n = \exp(3i\omega t) z_n''(\tau).
\] (22c)

Here and above the appended primes denote of course differentiations with respect to the variable \( \tau, z_n'(\tau) \equiv dz_n(\tau)/d\tau \).

Note that by setting formally \( \omega = 0 \) one gets from (21a) \( \tau = t \) and from (22a) \( \tilde{z}_n(t) = z_n(t) \); hence in the \( \omega \to 0 \) limit the results reported in this Sec. 2.2 reduce to those of the preceding Sec. 2.1 (whenever this limit makes sense).

The change of dependent variables (22) entails that the equations of motion (2b) get replaced by the following Newtonian equations of motion for the new dependent variables \( \tilde{z}_n(t) \):

\[
\ddot{\tilde{z}}_n = -\frac{3}{2}(N - 2)i\omega \tilde{z}_n - \frac{1}{2}(3N - 4)i\omega^2 \tilde{z}_n - 6\tilde{z}_n \ddot{\tilde{z}}_n - 3(3N - 2)i\omega \tilde{z}_n^2 - 4\tilde{z}_n^3
\]
\[
+ \frac{3}{2}(\tilde{z}_n - i\omega \dot{\tilde{z}}_n + 2\tilde{z}_n \ddot{\tilde{z}}_n)\ddot{\tilde{z}}_n + 2 \sum_{\ell=1,\ell\neq n}^N \left( \frac{(\tilde{z}_n - i\omega \tilde{z}_n + 2\tilde{z}_n \ddot{\tilde{z}}_n)(\tilde{z}_\ell - i\omega \tilde{z}_\ell + 2\tilde{z}_\ell \ddot{\tilde{z}}_\ell)}{\tilde{z}_n - \tilde{z}_\ell} \right),
\]
\[
n = 1, \ldots, N,
\] (23a)

\[
\ddot{\eta} = \sum_{\ell=1}^N \left( \frac{\ddot{\tilde{z}}_\ell}{\tilde{z}_\ell^3} + 2\ddot{\tilde{z}}_\ell \right).
\] (23b)
And it is plain from Proposition 2.1 and the formulas (22) that the solution of the corresponding initial-value problem is provided by the following proposition.

**Proposition 2.3.** The $N$ coordinates $\tilde{z}_n(t)$ are the $N$ eigenvalues of the following $N \times N$ matrix $\tilde{U}(t)$:

$$
\tilde{U}(t) = \exp(i\omega t)[1 - \tau(t)\tilde{Y}(0)]^{-1}\tilde{Z}(0)
$$

$$
\cdot \{1 - \tau(t)\tilde{Y}(0) - \tau^2(t)\tilde{Z}(0)[1 - \tau(t)\tilde{Y}(0)]^{-1}\tilde{Z}(0)\}^{-1},
$$

with $\tau(t)$ defined as above, see (21a), and

$$
\tilde{Z}(0) = \text{diag}[\tilde{z}_n(0)], \quad \tilde{Z}_{nm}(0) = \delta_{nm}\tilde{z}_n(0), \quad n, m = 1, \ldots, N,
$$

$$
\tilde{Y}_{nm}(0) = \frac{1}{2}\delta_{nm}\left[\frac{\dot{\tilde{z}}_n(0)}{\tilde{z}_m(0)} - i\omega \right] + \frac{1}{2}(1 - \delta_{nm})\left[\frac{\dot{\tilde{z}}_m(0)}{\tilde{z}_m(0)} - i\omega + 2\tilde{z}_m(0)\right]^{1/2}
$$

$$
\times \left[\frac{\dot{\tilde{z}}_m(0)}{\tilde{z}_m(0)} - i\omega + 2\tilde{z}_m(0)\right]^{1/2}, \quad n, m = 1, \ldots, N.
$$

**Remark 2.6.** Clearly (see (21)) the matrix $\tilde{U}(t)$, see (24a), evolves periodically,

$$
\tilde{U}(t + T) = \tilde{U}(t).
$$

Hence the many-body problem characterized by the system of Newtonian equations of motion (23a) is isochronous, namely its generic solution evolves periodically with the fixed period $T$, or possibly with a period which is a, generally small, integer multiple of $T$; indeed, even though the $N \times N$ matrix $\tilde{U}(t)$ is itself periodic with period $T$, the time evolution of each of its $N$ eigenvalues — which now takes necessarily place in the complex $\tilde{z}$-plane (except in the $N = 1$ case, see below) — might feature a somewhat larger periodicity due to the possibility that over the time evolution different eigenvalues exchange their roles (for a discussion of this phenomenology see [8]). For a zero-measure set of initial data the time evolution is singular due to the eventual occurrence of a collision of two (or, even more exceptionally, more than two) particles.

**Remark 2.7.** For $N = 1$, the system (23a) reduces to the following (real) equation of motion for the single dependent variable $\tilde{z}_1(t) = \tilde{z}(t)$, reading

$$
\ddot{\tilde{z}} = \frac{3(\dot{\tilde{z}})^2}{2} + \frac{1}{2}\dot{\tilde{z}}^2 + 2\tilde{z}^3;
$$

and the solution of the corresponding initial-value problem reads

$$
\tilde{z}(t) = \frac{\tilde{z}(0)}{1 - a\sin(\omega t) - b\sin^2(\omega t/2)}, \quad a = \frac{\dot{\tilde{z}}(0)}{\omega\tilde{z}(0)}, \quad b = 1 + 4\left[\frac{\tilde{z}(0)}{\omega}\right]^2 + a^2.
$$

Clearly in this case there are three equilibria: $\tilde{z}(t) = \tilde{z}^{(i)}$ with

$$
\tilde{z}^{(1)} = 0; \quad \tilde{z}^{(2)} = \frac{\dot{\tilde{z}}}{2}; \quad \tilde{z}^{(3)} = -\frac{\dot{\tilde{z}}}{2}.
$$
Remark 2.8. By a treatment analogous to that of Remark 2.3 one obtains from the system (23) the following ODE

\[ \ddot{\eta} = \left( \eta + (N - 1)i\omega \right)^2 + \omega^2, \]  

yielding

\[ \eta(t) = -\omega \left( (N - 1)i + \cotg \left( \frac{\omega(t + t_0)}{2} \right) \right), \]  

with \( t_0 \) defined of course by the following formula:

\[ \cotg \left( \frac{\omega t_0}{2} \right) = -\left( N - 1 \right)i - \frac{\eta(0)}{\omega}. \]

Hence an equivalent, nonautonomous, version of the many-body model (23) obtains by replacing in the equations of motion (23a) the expression (23b) of the collective coordinate \( \eta \) in terms of \( z_n \) and \( \dot{z}_n \) with its explicit time-dependent expression (28).

In the isochronous case the phenomenology of the equilibria is a bit less simple than in the nonisochronous case (see above Proposition 2.2). To describe the situation it is convenient to rescale the equilibrium coordinates as follows:

\[ \tilde{z}_n(t) = \frac{\omega^{1/2}}{\omega} \zeta_n, \quad n = 1, \ldots, N. \]

For \( N = 1 \), the only 3 equilibria are those reported above (see Remark 2.7), corresponding to the 3 rescaled values \( \zeta^{(1)} = 0, \zeta^{(2)} = 1, \zeta^{(3)} = -1 \).

For \( N \geq 2 \), the equilibrium configurations (which are of course defined up to permutations) are detailed by the following Proposition 2.4.

Proposition 2.4. For \( N \geq 2 \), there are three types of equilibria of the system (23).

The first type features (rescaled) equilibrium coordinates \( \zeta_n \) all of which take either one or the other of the two special values 1 or 0, say \( N_0 \) of them take the value 0 and \( N_1 = N - N_0 \) of them take the value 1, with \( N_0 \) an arbitrary non-negative integer not exceeding \( N, 0 \leq N_0 \leq N \).

The second type features \( N_0 \) (rescaled) equilibrium coordinates taking the value 0, \( N_1 = N - N_0 - 1 \) taking the special value 1 (of course now with 0 \( \leq N_0 \leq N - 1 \)) and the remaining one taking the value \( 3N_0 - 1 \).

The third type features \( N - 2 \) (rescaled) equilibrium coordinates taking the value 1 and the remaining two coordinates taking the two values

\[ \zeta^{(1)} = \zeta, \quad \zeta^{(2)} = -\zeta; \quad \zeta^{(1)} = 1 + \zeta, \quad \zeta^{(2)} = 1 - \zeta, \]  

with \( \zeta \) an arbitrary number. Note that the solution of the third type also belongs to the first type (with \( N_0 = 2 \)) for \( \zeta = 0 \), and it also belongs to the second type (with \( N_0 = 1 \)) for \( \zeta = \pm 1 \).

The behavior of the isochronous system (23a) in the neighborhood of its equilibrium configuration is described by an, of course solvable, dynamical system of goldfish type which is itself interesting. We now exhibit the simplest instance corresponding to the first type.
New Solvable Many-Body Model of Goldfish Type

of equilibria, see Proposition 2.4, leaving to the alert reader the derivation of the systems corresponding to the equilibria of second and third types. To this end we set

\[ \tilde{z}_n(t) = \frac{\ell_n}{2} \tilde{x}_n(t), \quad n = 1, \ldots, N_0, \]  
\[ \tilde{z}_{N_0+n}(t) = \frac{\ell_n}{2} (1 + \epsilon n(t)), \quad n = 1, \ldots, N_1 = N - N_0. \]  

(31a) (31b)

Treating \( \epsilon \) as an infinitesimal constant, it is then a matter of trivial if tedious algebra to get the equations of motion characterizing the evolution of the \( N_0 \) coordinates \( \tilde{x}_n(t) \) and the \( N_1 \) coordinates \( \tilde{y}_n(t) \) (where of course \( N_0 + N_1 = N \), see (31b)):

\[ \ddot{x}_n = \frac{3}{2} \tilde{\rho} - (N_0 - 2) \omega \dot{x}_n - \frac{2}{3} \left[ \tilde{\rho} - (N_0 - 1) \omega \right] \tilde{x}_n \]
\[ + 2 \sum_{\ell=1, \ell \neq n}^{N_0} \frac{(\dot{\tilde{\varphi}} - \omega \dot{\varphi}_n)(\dot{\tilde{x}}_\ell - \omega \dot{\varphi}_\ell)}{\tilde{x}_n - \tilde{x}_\ell}, \quad n = 1, \ldots, N_0; \]  
\[ \ddot{y}_n = \frac{3}{2} (\tilde{\rho} - N_0 \omega) \dot{y}_n + 2 \sum_{\ell=1, \ell \neq n}^{N_1} \left( \frac{\tilde{\rho}_n}{y_n - y_\ell} \right), \quad n = 1, \ldots, N_1; \]  

(32a) (32b)

where

\[ \tilde{\rho} \equiv \tilde{\rho}(t) = \sum_{j=1}^{N_0} \frac{\tilde{z}_j(t)}{\tilde{x}_j(t)}. \]  

(32c)

This is a new (of course autonomous, solvable and isochronous) model of goldfish type. Note that the system (32a) involves only the \( N_0 \) coordinates \( \tilde{x}_n \), while the system (32b) involves, in addition to the \( N_1 \) coordinates \( \tilde{y}_n \), also the \( N_0 \) coordinates \( \tilde{x}_n \), albeit only via the quantity \( \tilde{\rho} \), see (32c).

Remark 2.9. It is easily seen — via a treatment analogous to that of Remarks 2.3 and 2.8 — that the system (32a) with (32c) entails the following time evolution of the quantity \( \tilde{\rho} \equiv \tilde{\rho}(t) \):

\[ 2 \dot{\tilde{\rho}} = (\tilde{\rho} + (N_0 - 1) \omega) \dot{\varphi}^2 + \omega^2 \]  

(33a)

implying

\[ \tilde{\rho}(t) = -\omega \left( (N_0 - 1) i + \cotg \left( \frac{\omega(t + \tilde{\varphi}(t))}{2} \right) \right), \]  

(33b)

where of course the constant \( \tilde{\varphi} \) is related to the initial data \( \tilde{x}_n(0), \dot{\tilde{x}}_n(0), n = 1, \ldots, N_0 \), by the formula

\[ \cotg \left( \frac{\omega(0)}{2} \right) = -(N_0 - 1) i - \frac{\tilde{\rho}(0)}{\omega}. \]  

(33c)

with (32c). The insertion of this expression, (33b), into (32a) and (32b) transforms these two autonomous systems of Newtonian equations of motion (the second of which was coupled
to the first via (32c)) into two, apparently decoupled, *nonautonomous* systems, featuring however in their equations of motion the parameter $I_0$ defined in terms of the initial data $\bar{x}_n(0), \bar{y}_n(0), n = 1, \ldots, N$, by the formula (33c) (but this parameter $I_0$ only entails a, generally complex, shift of the time coordinate; hence its role is quite marginal). Note that a condition necessary and sufficient to ensure that these equations of motion do not become singular over time is that the initial data yield for the quantity $\bar{t}_0$ a value which is *not real* (i.e., the right-hand side of (33c) should not be real). Also note that, if consideration is limited to the *nonautonomous* system of goldfish type (32b) with (33b), reading

$$\dot{\bar{t}}_n = -\frac{3}{2}\left\{i + \cotg \left[\frac{2z(t + t_0)}{2}\right]\right\} \dot{\bar{t}}_n + 2 \sum_{\ell=1,\ell\neq n}^{N} \{\bar{y}_n \bar{y}_\ell \bar{y}^{-1}\}, \quad n = 1, \ldots, N,$$  

the quantity $\bar{t}_0$ can be evidently considered just an arbitrary constant (playing a quite marginal role), as well as the positive integer $N$. This *nonautonomous* many-body problem of goldfish type is of course *solvable* and *isochronous* (to the best of my knowledge, a new finding).

Finally, let us also display the *solvable* *isochronous* dynamical system satisfied by the $N$ dependent variables $\bar{c}_m(t)$ related to the $N$ variables $\bar{z}_n(t)$ (evolving according to the *isochronous* system of goldfish type (23)) by the analog of the relation (16a), reading

$$\bar{\psi}(z, t) = \prod_{n=1}^{N}[z - \bar{z}_n(t)] = z^N + \sum_{m=0}^{N} \bar{c}_m(t)z^{N-m},$$  

which of course entails

$$\sum_{n=1}^{N}(\bar{z}_n) = -\bar{c}_1$$  

and (see, if need be, [4, Eq. (A.11)])

$$\sum_{n=1}^{N}\left(\frac{\dot{z}_n}{\bar{z}_n}\right) = \frac{\dot{c}_N}{c_N}$$  

Again, the derivation from (23a) of the following nonlinear system of Newtonian equations of motion for the $N$ coefficients $\bar{c}_m$ is a standard, if tedious, task, facilitated by the relevant identities displayed in the [4, Appendix A]. This system reads as follows:

$$\ddot{\bar{c}}_m - \frac{3\bar{c}_N}{2\bar{c}_m} + \bar{e}_1 + \frac{\bar{e}_N}{2} \left[3(N-2) - 4m\right] \bar{c}_m + \left\{\frac{3\bar{c}_N}{\bar{c}_m}\bar{e}_1 - 2\bar{e}_1^2 - 2\bar{e}_1 + i\omega\left[3\bar{c}_N\bar{e}_N + (3N - m - 2)\bar{e}_1\right]\omega^m \left(\frac{3N-2}{2} - m\right)\right\} \bar{c}_m$$

$$- \left\{3(m+1)\bar{c}_N + 2(m-1)\bar{e}_1 + i\omega\left[4m^2 - 3(N-2)m + 5N + 2\right]\right\} \bar{c}_{m+1} + 2(2m+1)\bar{c}_{m+1} + 4m(m+2)\bar{e}_{m+2} = 0, \quad \bar{c}_{N+1} = \bar{c}_{N+2} = 0, \quad m = 1, \ldots, N.$$  

1250006-12
New Solvable Many-Body Model of Goldfish Type

Remark 2.10. An equivalent, but nonautonomous, version of these equations of motion obtains via the observation that (23b) and (28) with (35b) and (35c) entail the relation
\[
\dot{\tilde{c}}_N(t) = 2\tilde{c}_1(t) + \omega \left\{ (N-1)i - \cotg \left( \frac{\omega(t + \tilde{t}_0)}{2} \right) \right\},
\]
(37a)
of course with
\[
\omega \cotg \left( \frac{\omega\tilde{t}_0}{2} \right) = (N-1)i\omega - \left[ \dot{\tilde{c}}_N(0) - 2\tilde{c}_1(0) \right].
\]
(37b)

3. Proofs
In this section, we provide proofs of the findings reported but not proven in the preceding Sec. 2, i.e., essentially Proposition 2.1 and the findings about the equilibria (Propositions 2.2 and 2.4).

The starting point of our treatment is the trivially solvable matrix ODE
\[
\dot{W} = W^2,
\]
(38a)
the solution of which obviously reads
\[
W(t) = W(0)[I - tW(0)]^{-1}.
\]
(38b)
Here \(I\) is the unit \((2N) \times (2N)\) matrix, and here and below \(W \equiv W(t)\) is a \((2N) \times (2N)\) matrix.

It is now convenient to introduce the following block-matrix representation of the \((2N) \times (2N)\) matrix \(W \equiv W(t)\) in terms of two \(N \times N\) matrices \(U \equiv U(t), V \equiv V(t)\):
\[
W = \begin{pmatrix} V & U \\ U & V \end{pmatrix}.
\]
(39)

This yields the following system of matrix ODEs for the two \(N \times N\) matrices \(U \equiv U(t), V \equiv V(t)\):
\[
\dot{U} = UV + VU, \quad \dot{V} = U^2 + V^2.
\]
(40)

And it is easily seen (from (38b) and a bit of standard matrix algebra) that the solution of the corresponding initial-value problem yields the following expression of the \(N \times N\) matrix \(U \equiv U(t)\):
\[
U(t) = \left[ I - tV(0) \right]^{-1} U(0) \cdot \left\{ I - tV(0) - t^2 U(0) \left[ I - tV(0) \right]^{-1} U(0) \right\}^{-1}.
\]
(41)

Here and below \(I\) is the unit \(N \times N\) matrix.

We now introduce the \(N\) eigenvalues \(z_n(t)\) of this \(N \times N\) matrix \(U(t)\) by setting
\[
U(t) = R(t)Z(t)R(t)^{-1},
\]
(42a)
\[
Z(t) = \text{diag}[z_n(t)], \quad Z_{mm}(t) = \delta_{mm}z_n(t).
\]
(42b)

Remark 3.1. The diagonalizing matrix \(R(t)\) is only defined up to right-multiplication by an arbitrary diagonal matrix \(D \equiv D(t)\), \(D_{nn} = \delta_{nn}d_n\), namely it could be replaced by the matrix \(\tilde{R} = RD\) entailing \(R^{-1} = D^{-1}R^{-1}\).
Then, via an analogous formula (featuring the same matrix \( R(t) \) which diagonalizes the matrix \( U(t) \), see (42a)) we introduce the \( N \times N \) (generally nondiagonal) matrix \( Y \equiv Y(t) \) by setting

\[
V(t) = R(t)Y(t)[R(t)]^{-1},
\]

\[
Y_{nm}(t) = \delta_{nm}y_{n}(t) + (1 - \delta_{nm})Y_{nm}(t). \tag{43a}
\]

It is moreover convenient to introduce the \( N \times N \) matrix \( M \equiv M(t) \) by setting

\[
M(t) = [R(t)]^{-1}\dot{R}(t),
\]

\[
M_{nm}(t) = \delta_{nm}\mu_{n}(t) + (1 - \delta_{nm})M_{nm}(t). \tag{44a}
\]

**Remark 3.2.** The freedom entailed by the possibility to right-multiply the matrix \( R \) by an arbitrary diagonal matrix \( D \) (see Remark 3.1) entails that one is free to assign arbitrarily the diagonal elements \( \mu_{n}(t) \) of the matrix \( M(t) \), since the change from \( R \) to \( \dot{R} \) (see Remark 3.1) entails the corresponding change from \( \mu_{n} \) to \( \dot{\mu}_{n} = \mu_{n} + \dot{d}_{n}/d_{n} \).

Via (42a), (43a) and (44a) the matrix ODEs (40) then become

\[
\dot{Z} + [M,Z] = ZY + YZ, \tag{45a}
\]

\[
\dot{Y} + [M,Y] = Z^{2} + Y^{2}. \tag{45b}
\]

Let us now look at the diagonal and off-diagonal parts of these two matrix ODEs.

The diagonal part of (45a) yields

\[
\dot{z}_{n} = 2z_{n}y_{n}, \quad n = 1, \ldots, N, \tag{46a}
\]

entailing

\[
y_{n} = \frac{\dot{z}_{n}}{2z_{n}}, \quad n = 1, \ldots, N, \tag{46b}
\]

The off-diagonal part of (45a) yields, componentwise,

\[
(z_{n} - z_{m})M_{nm} = (z_{n} + z_{m})Y_{nm}, \quad n \neq m, \quad n, m = 1, \ldots, N, \tag{47a}
\]

entailing

\[
M_{nm} = -\left(\frac{z_{n} + z_{m}}{z_{n} - z_{m}}\right)Y_{nm}, \quad n \neq m, \quad n, m = 1, \ldots, N. \tag{47b}
\]

The diagonal part of (45b) yields

\[
y_{n} = z_{n}^{2} + y_{n}^{2} + \sum_{\ell=1, \ell \neq n}^{N} \{Y_{n\ell}Y_{\ell n} - M_{n\ell}Y_{\ell n} + Y_{n\ell}M_{\ell n}\}, \quad n = 1, \ldots, N, \tag{48a}
\]

entailing, via (46b) and (47b),

\[
y_{n} = \frac{z_{n}^{2}}{4z_{n}} + \sum_{\ell=1, \ell \neq n}^{N} \left\{Y_{n\ell}Y_{\ell n} \left(1 + \frac{2z_{n} + z_{\ell}}{2z_{n} - z_{\ell}}\right)\right\}, \quad n = 1, \ldots, N. \tag{48b}
\]
hence, via (46a) and (46b),
\[ \ddot{z}_n = \frac{3z_n^2}{2z_n} + 2z_n^3 + 2z_n \sum_{\ell = 1, \ell \neq n}^N Y_{n\ell} y_{n\ell} \left( 3 + \frac{4z_n}{z_n - z_\ell} \right), \quad n = 1, \ldots, N. \] (49)

Finally, the off-diagonal part of (45b) yields, componentwise,
\[ Y_{nm} = \sum_{k=1}^N (Y_{nk} y_{nk} - M_{nk} y_{nk} + Y_{nk} M_{nk}), \quad n \neq m, \quad n, m = 1, \ldots, N, \] (50a)
hence, via (43b), (44b), (46b), (47b) and a bit of algebra,
\[ \frac{\ddot{Y}_{nm}}{Y_{nm}} = \frac{\ddot{z}_n}{z_n} + \frac{\ddot{z}_m}{z_m} - \frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} - \mu_n + \mu_m \]
\[ + \sum_{\ell = 1, \ell \neq m}^N \left[ \frac{Y_{n\ell} Y_{\ell m}}{Y_{nm}} \left( 3 + \frac{2z_\ell}{z_n - z_\ell} + \frac{2z_m}{z_m - z_\ell} \right) \right], \quad n \neq m, \quad n, m = 1, \ldots, N. \] (50b)

We now note that the system of $N$ ODEs (49) looks like a set of Newtonian equations of motion for the coordinates $z_n$, with the quantities $Y_{n\ell} y_{n\ell}$ playing the role of “coupling constants”. But the quantities $Y_{n\ell}$ are not constants; indeed their time evolution is determined by the system of ODEs (50b). To get an autonomous system of Newtonian evolution equations involving only the $N$ coordinates $z_n$ one must therefore find — if at all possible — a way to get rid of the $N(N - 1)$ quantities $Y_{nm}$, namely a way to express them in terms of the coordinates $z_n$ and their time derivatives $\dot{z}_n$ (while of course satisfying the $N(N - 1)$ ODEs (50b), using, if need be, the freedom to assign the $N$ quantities $\mu_n$, see Remark 3.2).

Somewhat miraculously the following ansatz allows to realize this goal:
\[ \mu_n = 0, \quad n = 1, \ldots, N, \] (51a)
\[ Y_{nm} = \frac{1}{2} \left( \frac{z_n}{z_m} + 2z_m \right)^{1/2} \left( \frac{2z_m}{z_n} + 2z_m \right)^{1/2}, \quad n \neq m, \quad n, m = 1, \ldots, N. \] (51b)

Indeed via this ansatz the system (49) coincides with the equations of motion (2a) while, via this very expression, (2a), of $z_n$, it is rather easily seen that the ansatz (51) satisfies identically the $N(N - 1)$ equations (50b). This concludes the main part of our proof of Proposition 2.1.

There remains to express the two $N \times N$ matrices $U(0)$ and $V(0)$ featured by the solution (41) in terms of the initial data $z_n(0), \dot{z}_n(0), n = 1, \ldots, N$. The simplest (and clearly permitted) way is to assign $K(0) = I$, thereby entailing, via (42a), $U(0) = Z(0), V(0) = Y(0)$. Then the solution (41) reproduces the formula (3a), while clearly (42b) yields the expression (3b) of $Z(0)$ and, via (43b), (46b) and (51b), one gets the expression (3c) of $Y(0)$.

The proof of Proposition 2.1 is thereby completed.

Next, let us consider the equilibria. Let us re-emphasize that the equilibrium coordinates $\tilde{z}_n, \ddot{z}_n = 0$ are always defined up to permutations.
For the nonisochronous case of Sec. 2.1, we begin by noting that the equilibrium configuration \( z_n = \bar{z}_n, \dot{z}_n = 0 \) corresponding to the system (2b) is clearly characterized by the following system of \( N \) algebraic equations for the \( N \) (time-independent) coordinates \( \bar{z}_n \):

\[
\frac{\ddot{z}_n}{z_n} \left(-2z_n + 3 \sum_{k=1}^{N} (\bar{z}_k) + 4 \sum_{\ell=k, \ell \neq n}^{N} \left( \frac{\dot{z}_\ell^2}{z_k - z_\ell} \right) \right) = 0, \quad n = 1, \ldots, N. \tag{52a}
\]

Assume now that \( K \) of the coordinates \( \bar{z}_n \) do not vanish, while the remaining ones do vanish, say, for definiteness, \( \bar{z}_n = 0 \) for \( n = K + 1, \ldots, N \) (with \( 0 \leq K \leq N \)). The \( K = 0 \) case corresponds to the special case of Proposition 2.2 with \( \bar{z} = 0 \). Hence hereafter \( K \geq 1 \). Then the above set of equations is reduced to the following system of \( K \) algebraic equations for the \( K \) numbers \( \bar{z}_k \):

\[
-2(2K - 3)\bar{z}_k - \sum_{j=1}^{K} (\bar{z}_j) + 4 \sum_{\ell=1, \ell \neq k}^{K} \left( \frac{\dot{z}_\ell^2}{z_k - z_\ell} \right) = 0, \quad k = 1, \ldots, K, \tag{53a}
\]

or equivalently

\[
-2(2K - 3)\bar{z}_k - \sum_{j=1}^{K} (\bar{z}_j) + 4 \sum_{\ell=1, \ell \neq k}^{K} \left( \frac{\dot{z}_\ell^2}{z_k - z_\ell} \right) = 0, \quad k = 1, \ldots, K. \tag{53b}
\]

The equivalence is of course implied by the identity

\[
\bar{z}_k^2 = \bar{z}_k^2 - (\bar{z}_k - \bar{z}_j)(\bar{z}_k + \bar{z}_j). \tag{54}
\]

On the other hand by summing the \( K \) equations of the system (53a) and using the identity

\[
2 \sum_{k=1, \ell \neq k}^{K} \left( \frac{\dot{z}_\ell^2}{z_k - z_\ell} \right) = -(K - 1) \sum_{k=1}^{K} (\bar{z}_k) \tag{55}
\]

(clearly implied by (54)), we get \( K \sum_{j=1}^{K} (\bar{z}_j) = 0 \) namely \( \sum_{j=1}^{K} (\bar{z}_j) = 0 \). Hence (53b) can now be simplified to read

\[
4 \sum_{\ell=1, \ell \neq k}^{K} \left( \frac{z_\ell}{z_k - z_\ell} \right) = 2(2K - 3), \quad k = 1, \ldots, K. \tag{56}
\]

Finally summing these \( K \) equations and using the identity

\[
2 \sum_{k=1, \ell \neq k}^{K} \left( \frac{z_\ell}{z_k - z_\ell} \right) = K(K - 1) \tag{57a}
\]

we clearly get the relation

\[
2K(K - 1) = 2K(2K - 3) \quad \text{hence} \quad K = 0 \text{ or } K = 2. \tag{57b}
\]

It is then trivial to complete the proof of Proposition 2.2 by noting that (56) with \( K = 2 \) implies \( \bar{z}_1 = \bar{z}, \bar{z}_2 = -\bar{z} \) with \( \bar{z} \) arbitrary.
In the isochronous case of Sec. 2.2 it is convenient to utilize the rescaling (29) of the coordinates $\bar{z}_n$ identifying the equilibrium configurations. Then clearly from (23a) we get the following version of the system of $N$ algebraic equations determining the $N$ numbers $\zeta_n$:

$$\zeta_n (1 - \zeta_n) \left\{ 3N - 4 - 3\sigma + 2\zeta_n + 4 \sum_{\ell=1,\ell\neq n}^{N} \frac{\zeta(1 - \zeta)}{\zeta - \zeta' \zeta} \right\} = 0, \quad n = 1, \ldots, N, \tag{58a}$$

where we set

$$\sigma \equiv \sum_{n=1}^{N} (\zeta_n). \tag{58b}$$

Our task here is to identify all the solutions of this system of $N$ algebraic equations. Each solution is characterized by $N$ values $\zeta_n$; of course they are always defined up to an arbitrary permutation of the $N$ indices $n$. Clearly there are two values of the coordinates $\zeta_n$ which play a special role, namely the values 0 and 1. Therefore, hereafter we assume that $N_0$ respectively $N_1$ of the $N$ numbers $\zeta_n$ have these special values 0 respectively 1, say, for definiteness,

$$\zeta_n = 0 \quad \text{for} \quad N - N_0 + 1 \leq n \leq N, \tag{59a}$$

$$\zeta_n = 1 \quad \text{for} \quad N - N_0 - N_1 + 1 \leq n \leq N - N_0, \tag{59b}$$

where of course $N_0$ and $N_1$ are two non-negative integers the sum of which does not exceed $N$ so that

$$K = N - N_0 - N_1, \quad 1 \leq K \leq N. \tag{59c}$$

Implicit in this ansatz is the assumption that for $\zeta = 0$ or $\zeta = 1$ the $n$th equation of the algebraic systems (58a) is automatically satisfied; moreover note that, by assuming here that $K$ is positive, we are hereafter excluding from consideration the trivial case in which all the $N$ numbers $\zeta_n$ either vanish or equal unity (i.e., the solution of first type in Proposition 2.4). Hence our task is now reduced to finding the $K$ solutions of the following system of $K$ algebraic equations

$$3(K + N_0) - 4 - 3S + 2\zeta_k + 4 \sum_{\ell=1,\ell\neq k}^{K} \frac{\zeta(1 - \zeta)}{\zeta_k - \zeta' \zeta} = 0, \quad k = 1, \ldots, K, \tag{60a}$$

with

$$S \equiv \sum_{k=1}^{K} (\zeta_k). \tag{60b}$$

Note that the number $N_1$ has disappeared from these equations (because $\sigma = S + N_1$, see (58b), (60b) and (59)), and that our treatment entails now the requirement that the solution of this system feature no number $\zeta_k$ which vanishes or equals unity,

$$\zeta_k \neq 0, \quad \zeta_k \neq 1, \quad k = 1, \ldots, K. \tag{60c}$$

For $K = 1$ the system (60) reduces to a single (linear) equation and it clearly yields $\zeta_1 = 3N_0 - 1$, as indicated above. This is the solution of second type in Proposition 2.4.
Likewise, for $K = 2$ the system (60) can be easily solved, and it is thereby seen to imply $N_0 = 0$ and to yield for $\zeta_1$ and $\zeta_2$ the two values (30) with $\zeta$ an arbitrary number. This is the solution of third type in Proposition 2.4.

To complete the proof of Proposition 2.4 there remains to show that the system (60) has no solution for $K \geq 3$. We proceed per absurdum, introducing the (monic) polynomial of degree $K$ featuring the $K$ numbers $\zeta_k$ determined by the system (60) as its $K$ zeros:

$$
\psi(\zeta) = \prod_{k=1}^{K} (\zeta - \zeta_k) = \sum_{k=0}^{K} (c_k \zeta^{K-k}), \quad c_0 = 1, 
$$

and then showing that the assumption that such a polynomial exist leads to contradictions.

Note that this definition, together with (60b), entails the relation

$$
c_1 = -S. 
$$

Next — using (61b) and, if need be, the formulas (A.4), (A.6a), (A.8b) and (A.8f) of [4] — we note that to the algebraic system (60a) satisfied by the $K$ numbers $\zeta_k$ there corresponds for the polynomial $\psi(\zeta)$ the following second-order ODE:

$$
\zeta \psi'' + \left( \frac{3N_0 - K - c_1}{2} \right) \psi' = \zeta^2 \psi'' - (2K - 3)\zeta \psi' + K(K-2)\psi.
$$

Here of course the appended primes denote differentiations with respect to the argument $\zeta$ of the polynomial $\psi(\zeta)$.

Likewise — using, if need be, the formulas (A.13g), (A.13c), (A.13h), (A.13d) and (A.13a) of [4] — it is easily seen that this ODE yields for the coefficients $c_k$, see (61a), the following recursion relation:

$$
(K + 1 - k) \left( \frac{3N_0 + K - c_1}{2} - k \right) c_{k-1} = k(k-2)c_k, \quad k = 1, 2, \ldots. 
$$

For $k = 1$ this formula yields (using $c_0 = 1$, see (61a))

$$
c_1 = K \left( 1 + \frac{3N_0}{K-2} \right). 
$$

Then, for $k = 2$, we get from (63) either $c_1 = 0$ which is inconsistent with (64) for $K \geq 3$ and $N_0 \geq 0$, or

$$
c_1 = 3N_0 + K - 4 
$$

namely, via (64),

$$
2K + 3N_0 = 4 
$$

which also cannot be satisfied for $K \geq 3$ and $N_0 \geq 0$. The proof of Proposition 2.4 is thereby completed.
Acknowledgment

It is a pleasure to thank my friend Mario Bruschi for the suggestion to use the solvable matrix equation (40) as starting point for the search of a new solvable many-body problem.
