A LIMITING ABSORPTION PRINCIPLE FOR HELMHOLTZ SYSTEMS AND TIME-HARMONIC ISOTROPIC MAXWELL’S EQUATIONS

LUCREZIA COSSETTI, RAINER MANDEL

Abstract. In this work we investigate the $L^p - L^q$-mapping properties of the resolvent associated with the time-harmonic isotropic Maxwell operator. As spectral parameters close to the spectrum are also covered by our analysis, we obtain an $L^p - L^q$-type Limiting Absorption Principle for this operator. Our analysis relies on new results for Helmholtz systems with zero order non-Hermitian perturbations. Moreover, we provide an improved version of the Limiting Absorption Principle for Hermitian (self-adjoint) Helmholtz systems.

1. Introduction

The propagation of electromagnetic waves in continuous three-dimensional media is governed by the Maxwell’s equations. They consist of four equations, two vectorial and two scalar ones in the unknowns $\mathcal{D}$ and $\mathcal{E}$ (the electric fields) and $\mathcal{B}$ and $\mathcal{H}$ (the magnetic fields) for a given current density $\mathcal{J}$. Assuming the absence of electric charges their macroscopic formulation reads as follows

$$\partial_t \mathcal{D} - \nabla \times \mathcal{H} = -\mathcal{J}, \quad \partial_t \mathcal{B} + \nabla \times \mathcal{E} = 0,$$

$$\nabla \cdot \mathcal{D} = \nabla \cdot \mathcal{B} = 0,$$

with $\mathcal{D}, \mathcal{H}, \mathcal{B}, \mathcal{E}, \mathcal{J} : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{C}^3$. Notice that the restriction to the case of no electric charges ($\rho = 0$) influencing the propagation of the electromagnetic waves or, which is the same, the divergence-freeness of $\mathcal{D}$ and $\mathcal{B}$, implies $\nabla \cdot \mathcal{J} = 0$. Constitutive relations that specify the connections between the electric displacement $\mathcal{D}$ and the electric field $\mathcal{E}$ and between the magnetic flux density $\mathcal{B}$ and the magnetic field $\mathcal{H}$ are necessary for meaningful applications of this model. In general, these relations need not be simple, but in the physically realistic scenario where ferro-electric and ferro-magnetic materials are discarded and where the fields are weak enough, the material laws may be assumed to obey the following linear relations:

$$\mathcal{D} = \varepsilon(x) \mathcal{E}, \quad \mathcal{B} = \mu(x) \mathcal{H}.$$  \hspace{1cm} (2)

Here $\varepsilon$ and $\mu$ embody the permittivity respectively the permeability of the medium. In general anisotropic materials, where the interaction of fields and matter not only depends on the position in the material but also on the direction of the fields, these quantities are mathematically represented as tensors. In this paper we will be exclusively concerned with the case of isotropic (i.e. direction-independent) media where $\varepsilon$ and $\mu$ are scalar-valued functions on $\mathbb{R}^3$. For a more detailed description of Maxwell’s equations we refer the reader to [27,34].

We will focus on monochromatic waves only, i.e., electromagnetic fields $\mathcal{E}, \mathcal{D}, \mathcal{B}, \mathcal{H}, \mathcal{J}$ that are periodic functions of time with the same frequency $\omega \in \mathbb{R} \setminus \{0\}$, more specifically $\mathcal{E}(x,t) := e^{i\omega t} \mathcal{E}(x)$, $\mathcal{D}(x,t) := e^{i\omega t} \mathcal{D}(x)$, $\mathcal{B}(x,t) := e^{i\omega t} \mathcal{B}(x)$, $\mathcal{H}(x,t) := e^{i\omega t} \mathcal{H}(x)$, $\mathcal{J}(x,t) := e^{i\omega t} \mathcal{J}(x)$ for vector fields $\mathcal{E}, \mathcal{D}, \mathcal{B}, \mathcal{H}, \mathcal{J} : \mathbb{R}^3 \to \mathbb{C}^3$. This gives rise to the following time-harmonic analogue of Maxwell’s equations once the linear constitutive relations from (2) are imposed:

$$i \omega \varepsilon \mathcal{E} - \nabla \times \mathcal{H} = -\mathcal{J}, \quad i \omega \mu \mathcal{H} + \nabla \times \mathcal{E} = 0.$$  \hspace{1cm} (3)

In this paper we are interested in the following slightly more general model

$$i \zeta \varepsilon \mathcal{E} - \nabla \times \mathcal{H} = -\mathcal{J}_e, \quad i \zeta \mu \mathcal{H} + \nabla \times \mathcal{E} = \mathcal{J}_m.$$  \hspace{1cm} (4)

where $\zeta \in \mathbb{C}$ and where both electric and magnetic current densities $J_e$ and $J_m$ are included. Allowing for spectral parameters $\zeta \in \mathbb{C} \setminus \mathbb{R}$ reflects the so-called Ohm’s law for conducting media, which asserts that the current $J$ induced by the electric field $E$ can be described (in linear approximation) by $J = \sigma E + J_e$, where $\sigma : \mathbb{R}^3 \to \mathbb{R}$ represents the conductivity and $J_e$ is the external current density. Thus, plugging in Ohm’s law into (3) one gets that the first equation in (3) can be rewritten as

$$i(\omega e - i\sigma)E - \nabla \times H = -J_e,$$

which motivates the interest in the model (3).

The main purpose of this paper is to prove an $L^p$-type Limiting Absorption Principle for the time-harmonic Maxwell’s equations (1). Roughly speaking, proving a Limiting Absorption Principle means proving existence and continuity of the resolvent operator up to the essential spectrum. In the context of the Maxwell system (1) this translates into studying the boundedness of solutions $(E_\zeta, H_\zeta)$ of (1) with $\text{Im}(\zeta) \neq 0$ and characterizing their limits as $\text{Im}(\zeta) \to 0^\pm$. In this paper we shall prove the following result.

**Theorem 1.** Let $\omega \in \mathbb{R} \setminus \{0\}$ and assume that $1 \leq p, q \leq \infty$ satisfy

$$\frac{2}{3} \leq \frac{1}{p} < 1, \quad \frac{1}{6} < \frac{1}{q} < \frac{1}{3}, \quad \frac{2}{3} \leq \frac{1}{p} - \frac{1}{q} < \frac{2}{3}, \quad 0 \leq \frac{1}{p} - \frac{1}{q} < \frac{1}{3}. \quad (5)$$

Moreover assume that there are $\varepsilon_{\infty}, \mu_{\infty} > 0$ such that

(A1) $\varepsilon, \mu \in W^{1,\infty}(\mathbb{R}^3)$ are uniformly positive,

(A2) $|\nabla(\mu\varepsilon) + |\varepsilon\mu - \varepsilon_{\infty}\mu| + |\nabla\varepsilon|^2 + |\nabla\mu|^2 + |D^2\varepsilon| + |D^2\mu| \in L_+^q(\mathbb{R}^3) + L^2(\mathbb{R}^3),$

(A3) $|\nabla(\mu\varepsilon) + |\varepsilon\mu - \varepsilon_{\infty}\mu| \in L_+^{\frac{q}{2}}(\mathbb{R}^3) + L^{\frac{q}{2}}(\mathbb{R}^3)$ where $q \in [q_1, q_2]$ and $(p, \tilde{p}, q_1), (p, \tilde{p}, q_2)$ satisfy (3).

Then for all divergence-free vector fields $J_e, J_m \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^q(\mathbb{R}^3; \mathbb{C}^3)$, there are weak solutions $(E^\omega_+, H^\omega_+)$ in $L^q(\mathbb{R}^3; \mathbb{C}^6) \cap H^{1,6}(\mathbb{R}^3; \mathbb{C}^3)$ of the time-harmonic Maxwell system (1) with $\zeta = \omega$ satisfying

$$\|(E^\omega_+, H^\omega_+)\|_q \leq C(\omega) \left( \|(J_e, J_m)\|_p + \|(J_e, J_m)\|_{\tilde{p}} \right) \quad (6)$$

where $\omega \mapsto C(\omega)$ is continuous on $\mathbb{R} \setminus \{0\}$. Moreover the following holds:

(i) We have $(E_\zeta, H_\zeta) \to (E^\omega_+, H^\omega_+)$ in $L^q(\mathbb{R}^3; \mathbb{C}^6) \cap H^{1,6}(\mathbb{R}^3; \mathbb{C}^6)$ as $\zeta \to \omega \pm i0$ where $(E_\zeta, H_\zeta) \in H^1(\mathbb{R}^3; \mathbb{C}^6)$ is the unique weak solution solution of (1) with divergence-free vector fields $J^\omega_e, J^\omega_m \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^q(\mathbb{R}^3; \mathbb{C}^3)$ converging to $J_e, J_m$ in $L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^q(\mathbb{R}^3; \mathbb{C}^3)$, respectively.

(ii) The function $u^\omega_+ := (\varepsilon^\omega E^\omega_+, \mu^\omega H^\omega_+) \in L^q(\mathbb{R}^3; \mathbb{C}^6)$ solves the Helmholtz system

$$(\Delta + \omega^2 \varepsilon_{\infty}\mu_{\infty})u^\omega_+ + V(\omega)u^\omega_+ = L_1(\omega)\tilde{J} + L_2\tilde{J}$$

where $V(\omega), L_1(\omega), L_2, \tilde{J}$ are defined at the beginning of Section 3. More precisely, $u^\omega_+$ satisfies the integral equation (4). (iii) If additionally $J_e, J_m \in L^q(\mathbb{R}^3; \mathbb{C}^3)$, then $(E^\omega_+, H^\omega_+) \in W^{1,6}(\mathbb{R}^3; \mathbb{C}^6).$

**Remark 2.**

(a) We shall not provide explicit values for the constants $C(\omega)$, but content ourselves with proving estimates that are uniform on compact subsets of $\mathbb{R} \setminus \{0\}$. This is indeed sufficient for the existence of a map $\omega \mapsto C(\omega)$ that is continuous on $\mathbb{R} \setminus \{0\}$.

(b) The convergence in $H_0^{1,6}(\mathbb{R}^3; \mathbb{C}^6)$ is stated for simplicity. By standard elliptic regularity theory, convergence holds in $W_{\text{loc}}^{r,6}(\mathbb{R}^3; \mathbb{C}^6)$ where $r \geq 1$ depends on the local regularity of $\varepsilon, \mu, J_e, J_m$.

(c) If the currents $J^\omega_e, J^\omega_m$ also converge in $L^q(\mathbb{R}^3; \mathbb{C}^3)$ then one finds $(E_\zeta, H_\zeta) \to (E^\omega_+, H^\omega_+)$ in $W^{1,6}(\mathbb{R}^3; \mathbb{C}^6)$.

In the context of Limiting Absorption Principles of time-harmonic Maxwell’s equations only few results are available. Picard, Weck and Witsch proved a Limiting Absorption Principle in weighted $L^2$-spaces (similar to [2]) for time-harmonic Maxwell’s equations in an exterior domain with boundary conditions $\nu \wedge E = 0$, see [41] Theorem 2.10. Since this result is based on Fredholm’s Alternative, the frequencies $\omega \in \mathbb{R} \setminus \{0\}$ are assumed not to belong to a discrete (possibly empty) set of eigenvalues. As in Agmon’s fundamental paper [2] about the perturbed Helmholtz equation, the permittivity $\varepsilon$ and permeability $\mu$ are assumed to be isotropic.
and to decay to some positive constants at infinity faster than \(|x|^{-1}\). Despite some quantitative differences, this is similar to our assumptions (A1),(A2),(A3). The Limiting Absorption Principle in weighted \(L^2\)-spaces and applications to Strichartz estimates for Maxwell’s Equations in isotropic media were recently proved by D’Ancona and Schnaubelt [11].

In the anisotropic case, still in weighted \(L^2\)-spaces, related results were obtained by Pauly [43, Theorem 3.5]. We note that these results also apply to discontinuous \(\varepsilon,\mu\), which indicates that (A1) may be relaxed. For results in the \(L^p - L^q\)-setting as in this paper we refer to 37,48. In a recent work [11, Theorem 2.1] by Nguyen and Sil, in an \(L^2\)-framework, the Limiting Absorption Principle is studied in the case of anisotropic sign-changing coefficients on \(\mathbb{R}^3\) that are used to describe metamaterials. We also mention [40, Lemma 4-6] where the author studied existence, uniqueness and stability of solutions to the anisotropic Maxwell system when the coefficients are constant outside a bounded set and piecewise \(C^1(\mathbb{R}^3)\).

As far as we can see, our contribution is the first dealing with \(L^p\)-estimates for time-harmonic Maxwell’s equations. All the aforementioned results relate to the three-dimensional Maxwell operator. A Limiting Absorption Principle in periodic 1D waveguides can be found in the recent preprint by De Nittis, Moscolari, Richard and Tiedra de Aldecoa [12]. Further relevant tools for Limiting Absorption Principles such as Carleman inequalities or Unique Continuation results can be found in [15,42].

In view of the Limiting Absorption Principle from Theorem 1 and in particular of the resolvent-type estimate \(\mathbf{(3)}\), it must be expected that embedded eigenvalues of the Maxwell operator do not exist under the assumptions of Theorem 1. In the classical Fredholm theoretical approaches from [2,11] this is even a necessary condition for the Limiting Absorption Principle to hold. Nonetheless, the proof of our Theorem 1 does not allow to derive the absence of embedding eigenvalues directly. For this reason we prove the absence of embedded eigenvalues separately. This is object of the following result. As we shall see in Section 3 this heavily relies on Carleman estimates by Koch and Tataru [33].

**Theorem 3.** Assume (A1),(A2) for some \(\varepsilon_\infty,\mu_\infty > 0\), \(\zeta \in \mathbb{C}\) and let \((E,H) \in H^1_{\text{loc}}(\mathbb{R}^3;\mathbb{C}^6)\) be a weak solution of the homogeneous \((J_0 = J_m = 0)\) time-harmonic Maxwell system \(\mathbf{(4)}\) that satisfies \((1+|x|)^{\gamma-\frac{2}{p}}(|E|+|H|) \in L^2(\mathbb{R}^3)\) for some \(\tau_0 > 0\). Then \(E \equiv H \equiv 0\).

In relation with non-existence of eigenvalues of the Maxwell operator, we should mention the remarkable contribution of Eidus [14]. Here the author proves that for sufficiently smooth, real-valued, symmetric and positive definite matrices \(\varepsilon,\mu\) there are no nontrivial solutions of the homogeneous \((J_0 = J_m = 0)\) time-harmonic Maxwell system \(\mathbf{(4)}\) with \(\zeta \in \mathbb{R} \setminus \{0\}\) imposing that the matrix-valued coefficients \(\varepsilon\) and \(\mu\) are short-range perturbations of the identity and satisfy the repulsivity condition

\[
(\partial_r (r\varepsilon) u, w)_{L^2} \geq \gamma ||u||^2_{L^2}, \quad r = |x|,
\]

for some positive \(\gamma\) (and analogous condition for \(\mu\)). We stress that in [14] the necessity of condition \(\mathbf{(4)}\) for the absence of bound states is not discussed, as a matter of fact in [14] condition \(\mathbf{(7)}\) is only introduced as a sufficient condition. We refer the reader to [11, Theorem 4.2] for details. In the same paper an analogous result in the isotropic case is proved, which shares some similarity with Theorem 3. In this case it turns out that the nonexistence of eigenvalues follows without the need of the repulsive condition \(\mathbf{(7)}\) stated above (see [14, Theorem 4.4]). In the proofs of Theorem 1 and 3 we will use that for any given solution \((E,H)\) of the Maxwell system \(\mathbf{(4)}\) the function \((\hat{E},\hat{H}) := (\hat{\varepsilon}\hat{E},\hat{\mu}\hat{H})\) solves a linear Helmholtz system with complex-valued zeroth order perturbations. The difficulty arises from the fact this perturbation is non-Hermitian in general. The tools that we will need in the analysis of this particular system are inspired from the theory for Helmholtz systems with Hermitian perturbations that we will develop first. For the sake of simplicity we restrict our attention to the case \(n \geq 3\).

**Theorem 4.** Let \(n,m \in \mathbb{N}\), \(n \geq 3\), \(\zeta \in \mathbb{C} \setminus \mathbb{R}\). Assume \(V = \nabla^T \in L^\infty(\mathbb{R}^n;\mathbb{C}^{m \times m}) + L^{\frac{n+1}{2n}}(\mathbb{R}^n;\mathbb{C}^{m \times m})\) and that \(1 \leq p,q \leq \infty\) satisfy

\[
\frac{n + 1}{2n} < \frac{1}{p} \leq 1, \quad \frac{(n - 1)^2}{2n(n + 1)} < \frac{1}{q} < \frac{n - 1}{2n}, \quad \frac{2}{n + 1} < \frac{1}{p} - \frac{1}{q} \leq 2.
\]
Then $R(\zeta) := (\Delta I_m + V(x) + \zeta I_m)^{-1} : L^p(\mathbb{R}^n; \mathbb{C}^m) \to L^q(\mathbb{R}^n; \mathbb{C}^m)$ exists as a bounded linear operator and extends by pointwise convergence to the positive half-axis via

$$R(\lambda \pm i0) f := \lim_{\zeta \to \lambda \pm i0} R(\zeta) f, \quad \text{in } L^q(\mathbb{R}^n; \mathbb{C}^m),$$

for any $f \in L^p(\mathbb{R}^n; \mathbb{C}^m)$ and $\lambda > 0$.

Remark 5.

(a) We will actually prove a slightly stronger result than Theorem 4. We will show that all conclusions mentioned in this theorem are true assuming $V = \nabla^T \in L^{\tilde{p}}(\mathbb{R}^n; \mathbb{C}^{m \times m}) + L^{\tilde{\kappa}}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ with $\tilde{\kappa} \leq \frac{n+1}{2}$ where the condition $\frac{(n-1)^2}{2(n+1)} \leq \frac{1}{q} < \frac{n-1}{2n}$ is replaced by the weaker one $\frac{4}{2n} - \frac{1}{\tilde{\kappa}} \leq \frac{1}{q} < \frac{n-1}{2n}$. In other words, Theorem 4 corresponds to the special case $\tilde{\kappa} = \frac{n+1}{2}$ of this stronger result.

(b) We assume $\zeta \in \mathbb{C} \setminus \mathbb{R}$ in order to guarantee the existence of the resolvent $R(\zeta)$. Notice that sign or smallness assumptions on $V$ may ensure the existence of well-defined resolvents on given parts of the real line.

(c) The limit in (5) is a pointwise limit and it is natural to ask whether this convergence also holds in the uniform operator topology. Ideas related to this question can be found in [24, p.46].

(d) The two-dimensional case $n = 2$ can in principle be discussed using the same techniques. We expect that the same statements hold for $V = \nabla^T \in L^{\tilde{p}}(\mathbb{R}^2; \mathbb{C}^{m \times m}) + L^{\tilde{\kappa}}(\mathbb{R}^2; \mathbb{C}^{m \times m})$ for some $\kappa > 1$.

To explain to what extent Theorem 4 improves earlier results, we first provide a short summary of the available literature about the scalar case $m = 1$. Goldberg and Schlag [20] were the first to go beyond the Hilbert space framework in which, since Agmon’s work [2], the Limiting Absorption Principles for self-adjoint Schrödinger operators were studied. They proved an $L^p$-type Limiting Absorption Principle that inspired our Theorem 4. For $n = 3$ they showed

$$\sup_{0 < \delta < 1, \lambda \geq \lambda_0} \|R(\lambda + i\delta)\|_{L^q(\mathbb{R}^3; L^{3/2})} \leq C(\lambda_0, V) \lambda^{-\frac{1}{2}}, \quad \lambda_0 > 0, \tag{9}$$

provided that $V \in L^{\tilde{p}}(\mathbb{R}^3) \cap L^p(\mathbb{R}^3)$, $p > \frac{3}{4}$. In [20, Proposition 1.3] it is even stated that the assumption on $V$ can be considerably weakened to $V \in L^{\tilde{p}+\varepsilon}(\mathbb{R}^3) + L^{\tilde{\kappa}-\varepsilon}(\mathbb{R}^3)$, $\varepsilon > 0$, provided that embedded eigenvalues for Schrödinger operators with such perturbations do not exist. The latter was meanwhile proved by Koch and Tataru [33, Theorem 3]. Huang, Yao and Zheng [24] generalized the result from [20] to the higher-dimensional case by proving that the estimate

$$\sup_{0 < \delta < 1, \lambda \geq \lambda_0} \|R(\lambda + i\delta)\|_{L^q(\mathbb{R}^n; L^{2(n+1)/(n+2)})} \leq C(\lambda_0, V) \lambda^{-\frac{n+1}{2}}, \quad \lambda_0 > 0,$$

holds for all potentials $V \in L^{\tilde{p}}(\mathbb{R}^n) \cap L^p(\mathbb{R}^n)$, $p > \frac{n}{2}$ and all $n \in \mathbb{N}, n \geq 3$. The most recent result in this direction is due to Ionescu and Schlag [26] where a new Limiting Absorption Principle was proved for a much larger class of potentials than the ones covered by the aforementioned results. As our Theorem 4 this result covers all $V \in L^{\tilde{p}}(\mathbb{R}^n) + L^{\tilde{\kappa}+\varepsilon}(\mathbb{R}^n)$ as one can check from (1.19) in [26]. In their Theorem 1.3 (d), the resolvent estimate

$$\sup_{\lambda \in I, 0 < \delta \leq 1} \|R(\lambda \pm i\delta)\|_{X \to X^*} \leq C(I, V)$$

is proved where $I \subset \mathbb{C} \setminus \{0\}$ is a compact set that does not intersect the set of nonzero eigenvalues. For the precise definition of the Banach space $X$ we refer to [26, p.400]. Notice that these estimates are self-dual in the sense that they bound the operator norms of the resolvents acting between some Banach space and the corresponding dual space. In this respect, our result from Theorem 4 is more general than [26]. Compared to [20,24], Theorem 4 requires for less integrability of the potential (including endpoint cases) and therefore improves the known results. Being given [33, Theorem 3], the generalization to Helmholtz systems ($m \geq 2$) is rather trivial.
Concerning Limiting Absorption Principles for Helmholtz equations \((m = 1)\) in other settings and under different assumptions we would like to mention the papers \(33,30\) (Morrey-Campanato spaces) and \(37\) for dissipative Helmholtz operators, \(29\) (sign-changing coefficients), \(36,55\) (periodic potentials) and \(7,38\) (critical potentials).

As anticipated (see again Proposition 1.3 in \(20\)), in the proof of a Limiting Absorption Principle, excluding embedded eigenvalues usually represents the discriminating step where the hypotheses on the potential come into play. The non-existence of positive eigenvalues for the Schrödinger operator has a long history. In 1959, Kato \(29\) proved that the Schrödinger operator \(-\Delta + V\) in \(L^2(\mathbb{R}^n)\) has no embedded eigenvalues if \(V\) is continuous and such that \(V(x) = o(|x|^{-1})\) as \(|x| \to \infty\). Later Simon \(19\) improved Kato’s result allowing also for long-range potentials. More precisely he considered potentials \(V\) which admit the decomposition \(V = V_1 + V_2\), with \(V_1(x) = o(|x|^{-1})\), \(V_2(x) = o(1)\), and \(\omega_0 := \limsup_{|x| \to \infty} x \cdot \nabla V_2(x) < \infty\). Under these conditions he proved, in three dimensions, the absence of eigenvalues above the positive threshold \(\omega_0\). This result was later improved by Agmon in \(1\), where he lowered the threshold to \(\omega_0/2\) covering also all dimensions. Similar results were also proved by Froese et al. in \(19\) (see also \(5,10,17,18\) for related results). Using a different approach based on Carleman estimates Ionescu-Jerison in \(25\) Theorem 2.5 showed that for all \(\varepsilon > 0\) there are \(V \in L_\text{loc}^{3/2-\varepsilon}(\mathbb{R}^n)\) such that the scalar Schrödinger operator \(-\Delta + V\) has embedded eigenvalues with rapidly decaying eigenfunctions. Thus, the exponent \(3/2+\varepsilon\) in our assumption is optimal. Notice that, as far as asymptotic decay conditions are investigated, a higher exponent in the Lebesgue space allows to cover a wider class of perturbations. On the other hand, the optimality of the exponent \(3/2\) is not entirely clear, even though it is known that standard properties of Schrödinger operators like semi-boundedness need not hold for potentials with lower integrability. In \(30,32\) Theorem 1.a) it is shown that 0 can be an embedded eigenvalue when potentials in the class \(L^{\infty}(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)\) with \(\kappa < \frac{3}{2}\) are considered, see also \(28\) Remark 6.5].

Up to the authors’ knowledge, a counterexample for non-zero eigenvalues is not known.

As customary, a basic tool for ruling out embedded eigenvalues is a suitable Carleman estimate. In our case, due to the weak and almost optimal conditions \(V = \nabla V \in L_\text{loc}^{3/2}(\mathbb{R}^n; C^{m\times m}) + L_\text{loc}^{3/2}(\mathbb{R}^n; C^{m\times m})\), we need to use the fine Carleman estimate for scalar Schrödinger operators provided by Koch and Tataru in \(33\), which allows to cover this wide class of potentials. We stress that the possibility to use a scalar Carleman estimate in our vector-valued setting only works because the chosen weight in the Carleman bound in \(33\) Proposition 4] does not depend on the solution itself. Indeed, this fact ultimately permits to sum up the estimates obtained for the components and to get an estimate for the full vector field. Analogous results for Helmholtz systems with first order perturbations cannot be obtained in this way since the weights in the corresponding Carleman estimates from \(33\) (see Theorem 8 and Theorem 11) depend on the solution itself. Hence, it is not guaranteed that one Carleman weight works for all components, which is why systems with first order perturbations appear to be more difficult.

The rest of the paper is organized as follows: Section 2 is devoted to the proof of the Limiting Absorption Principle for Helmholtz systems with Hermitian coefficients stated in Theorem 1. The aforementioned relation between Maxwell’s equations \(1\) and Helmholtz systems will be discussed in Section 3. Here we also provide the proof of Theorem 3 about the absence of eigenvalues for the Maxwell system \(2\). Finally, in Section 4 we prove the most involved result of the paper, namely the Limiting Absorption Principle for Maxwell’s equations \(4\) from Theorem 1.

We conclude this introduction with the main notations used in this paper.

**Notations.**

* For \(Z \in \{\mathbb{R}, \mathbb{C}; \mathbb{R}^m, \mathbb{C}^m, \mathbb{R}^{m \times m}, \mathbb{C}^{m \times m}\}\) we shall shortly write \(\| \cdot \|_p := \| \cdot \|_{L^p(\mathbb{R}^n; Z)}\).

* \(B(X,Y)\) denotes the Banach spaces of bounded linear operators between Banach spaces \(X,Y\) equipped with the standard operator norm.

* We write \(V \in L^{[1,3]}(\mathbb{R}^n; Z) := L^{1}(\mathbb{R}^n; Z) + \bigcap_{p \geq 2} L^p(\mathbb{R}^n; Z)\) if \(V\) can be decomposed as \(V = V_1 + V_2\), with \(V_1 \in L^1(\mathbb{R}^n; Z)\) and \(V_2 \in L^p(\mathbb{R}^n; Z)\).

* \(\chi_B\) represents the indicator of a measurable subset \(B \subset \mathbb{R}^n\).
We stress that a good control of the right hand side with respect to the most delicate part of the argument. Once this is achieved, one obtains the desired estimate

where

\( I_m \) denotes the identity matrix in \( \mathbb{R}^{m \times m} \), \( m \in \mathbb{N} \).

* The notation \( I \) is used for the identity operator in some function space.

* We use the notation \( \lesssim \) where we want to indicate that we have an inequality \( \leq \) up to a constant factor which does not depend on the relevant parameters.

* \( H^1(\text{curl}; \mathbb{R}^3) := \{ u \in L^2(\mathbb{R}^3; \mathbb{C}^3) : \text{curl} \ u \in L^2(\mathbb{R}^3; \mathbb{C}^3) \} \).

* We adopt the following definition for the Fourier transform

\[
\hat{f}(\xi) := \mathcal{F}(f)(\xi) := \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} e^{-ix\cdot\xi} f(x) \, dx.
\]

2. The LAP for Helmholtz systems – Proof of Theorem 4

This section is concerned with the proof of Theorem 4 that relies on a well-known perturbative argument based on Fredholm operator theory. This strategy has its origin in the pioneering work by Agmon [2] where it was used to establish a Limiting Absorption Principle for Schrödinger operators acting between weighted \( L^2 \)-spaces. Since then, this technique has permeated many works in the subject. We refer to [13, 46, 50] for some remarkable earlier contributions.

We summarize Agmon’s approach as follows. Consider a reference operator \( H_0 \) and let \( H \) be a suitable perturbation of \( H_0 \), let \( \zeta \in \mathbb{C} \). The first step is to prove the existence of a right inverse \( R_0(\zeta) \) for the operator \( H_0 + \zeta \) satisfying an estimate of the form

\[
\| R_0(\zeta) f \|_{X_1} \leq C(\zeta) \| f \|_{X_2}, \quad (10)
\]

where \( X_1, X_2 \) are Banach spaces. In Agmon’s paper, for spectral parameters \( \zeta := \lambda > 0 \) and the Laplacian \( H_0 = \Delta \) such right inverses are constructed via the classical Limiting Absorption Principle for Helmholtz equations, namely by investigating the mapping properties of the resolvents \( R_0(\zeta) \) as \( \zeta \to \lambda \pm i0, \lambda > 0 \), see Theorem 4.1 [2]. This is a nontrivial task given that every such \( \lambda \) belongs to the essential spectrum of the (negative) Laplacian and therefore no such limits can exist when \( X_1 = X_2 = L^2(\mathbb{R}^n) \). In [2] this was circumvented by introducing suitable and, as a matter of fact, optimal weighted \( L^2 \)-spaces such that the operators \( R_0(\zeta) \) converge in \( \mathcal{L}(X_2, X_1) \) as \( \zeta \to \lambda \pm i0 \) (with different limits). In order to extend the estimate (10) to the perturbed operator \( H \) one assumes that \( V := H - H_0 \) is a relatively compact perturbation of \( H_0 \), meaning that the linear operator \( K(\zeta) := -R_0(\zeta)V \) is compact on \( X_1 \). In view of the formula

\[
H + \zeta = (H_0 + \zeta)(I - K(\zeta))
\]

a right inverse \( R(\zeta) \) for the operator \( H + \zeta \) is given by

\[
R(\zeta) := (I - K(\zeta))^{-1} R_0(\zeta)
\]

as soon as \( I - K(\zeta) : X_1 \to X_1 \) is bijective. By Fredholm theory, it suffices to verify injectivity, which is the most delicate part of the argument. Once this is achieved, one obtains the desired estimate

\[
\| R(\zeta) f \|_{X_1} \leq C(\zeta) \| (I - K(\zeta))^{-1} \|_{X_1 \to X_1} \| f \|_{X_2}, \quad (11)
\]

We stress that a good control of the right hand side with respect to \( \zeta \) will be of central interest in the following.

In our context the reference operator \( H_0 \) and its perturbation \( H \) are the free and the perturbed matrix-valued Schrödinger operators, namely

\[
H_0 := \Delta, \quad H := \Delta + V(x),
\]

where \( V = \nabla^T \in L^1 \left( \mathbb{R}^n \mid \mathbb{C}^{m \times m} \right) \) and \( m \in \mathbb{N} \). Here, the Laplacian \( \Delta \) acts as a diagonal operator on each of the \( m \) components and \( \zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0} \) or \( \zeta = \lambda \pm i0, \lambda > 0 \) as we explain below.

According to the general strategy described above, to get an analogue of estimate (11) under our assumptions, we need to accomplish the following three steps:

Step 1: Provide \( L^p - L^q \) estimates for \( R_0(\zeta) \).
Step 2: Show that the linear operator \( K(\zeta) = -R_0(\zeta)V : L^p(\mathbb{R}^n; \mathbb{C}^m) \rightarrow L^q(\mathbb{R}^n; \mathbb{C}^m) \) is compact.

Step 3: Prove the injectivity of the Fredholm operator \( I - K(\zeta) : L^p(\mathbb{R}^n; \mathbb{C}^m) \rightarrow L^q(\mathbb{R}^n; \mathbb{C}^m) \).

We will see that Step 1 is essentially available in the literature. Only minor modifications will be needed to pass from the scalar to the vector-valued framework. To accomplish Step 2, which is rather standard, we will use the local compactness of Sobolev embeddings. So the main difficulty is to achieve Step 3. It will be accomplished with the aid of Carleman estimates by Koch and Tataru \(33\) and by exploiting the fact that \( V \) is Hermitian.

Our results from Theorem 4 even provide the uniform bounds in \( \mathbb{C} \setminus \mathbb{R}_{\geq 0} \)

\[
C(\zeta) := \|R_0(\zeta)\|_{p \rightarrow q} \lesssim |\zeta|^\frac{\beta}{2} |\frac{1}{p} - \frac{1}{q}| \quad \text{and} \quad \|(I - K(\zeta))^{-1}\|_{q \rightarrow q} \lesssim 1
\]
as well as continuity properties of \( \zeta \mapsto K(\zeta) \) and \( \zeta \mapsto (I - K(\zeta))^{-1} \) needed for the proof of \(8\). The following subsections are devoted to the proof of the aforementioned facts.

2.1. \( L^p - L^q \) estimates for \( R_0(\zeta) \). In the scalar case, optimal \( L^p - L^q \) resolvent estimates for \( n \geq 3 \) are originally due to Kenig, Ruiz and Sogge \(31\) Theorem 2.3 in the selfdual case of the functions \( R \) and \( \tilde{R} \) operator.

Proof. \( \) The estimate \(\ref{eq:R0_estimate}\) is available in the literature mentioned above. The existence of a bounded linear operator \( R_0(\lambda \pm i0) \rightarrow R_0(\lambda \pm i0) \) as \( \zeta \rightarrow \lambda \pm i0 \) follows from the uniform boundedness of the functions \( R_0(\zeta)f \) in \( L^q(\mathbb{R}^n) \) for \( \zeta \) near \( \lambda \) (see \(\ref{eq:R0_estimate}\)) and the continuity of Cauchy type integrals as in \(2\) Theorem 4.1]. We indicate how to prove that this convergence in fact holds in the strong sense. By density of test functions and \(\ref{eq:R0_estimate}\) it suffices to prove \( R_0(\zeta)f - R_0(\tilde{\zeta})f \rightarrow 0 \) for test functions \( f \in L^\infty(\mathbb{R}^n) \) as \( \zeta \rightarrow \tilde{\zeta}, \tilde{\zeta} \rightarrow \zeta_0 < \infty \) \(C^\infty) \) for \( \zeta \) near \( \lambda \). For simplicity we only consider the case \( \text{Im}(\zeta), \text{Im}(\tilde{\zeta}) > 0 \). Here we can use \( R_0(\zeta)f - R_0(\tilde{\zeta})f = (G_\zeta - G_{\tilde{\zeta}})f \) where, according to \(24\) p.46, we have for \( \zeta = \mu = 0, \text{Re}(\mu), \text{Im}(\mu) \geq 0 \) and \( \tilde{\zeta} = \tilde{\mu}^2 \) sufficiently close to \( \zeta \) with \( \text{Re}(\tilde{\mu}), \text{Im}(\tilde{\mu}) > 0 \).

\[
|G_\zeta(z) - G_{\tilde{\zeta}}(z)| \lesssim \begin{cases} 
|\mu - \tilde{\mu}| |z|^{3-n} & , \text{if } |z| \leq |\mu|^{-1} \\
|\mu - \tilde{\mu}| |\mu|^{-2} |z|^{\frac{n-3}{2}} & , \text{if } |\mu|^{-1} \leq |z| \leq |\mu - \tilde{\mu}|^{-1} \\
|\mu - \tilde{\mu}| |z|^{\frac{n-3}{2}} & , \text{if } |z| \geq |\mu - \tilde{\mu}|^{-1}.
\end{cases}
\]

So Young’s convolution inequality implies in view of \( q > \frac{2n}{n+1} \)

\[
\|R_0(\zeta)f - R_0(\tilde{\zeta})f\|_q \lesssim |\mu - \tilde{\mu}| |z|^{3-n} \chi_{|z| \leq |\mu|^{-1}} \|f\|_q + |\mu - \tilde{\mu}| |\mu|^{-2} \chi_{|z| \leq |\mu - \tilde{\mu}|^{-1}} \|f\|_q + \|\frac{|z|^{\frac{n+3}{2}} \chi_{|z| \geq |\mu - \tilde{\mu}|^{-1}}}{q} \|_q |f\|_q \\
\lesssim |\mu - \tilde{\mu}| + |\mu - \tilde{\mu}| \cdot |\mu - \tilde{\mu}|^{\frac{n+3}{2}} + |\mu - \tilde{\mu}|^{\frac{n+1}{2}} - \frac{n}{q}.
\]

\[= |\mu - \tilde{\mu}| + |\mu - \tilde{\mu}|^{\frac{n+1}{2}} - \frac{n}{q}.\]
Hence, \((R_0(\zeta)f)\) is a Cauchy sequence in \(L^q\) and thus converges. Since the limit must coincide with the weak limit, we get the conclusion. \(\square\)

The conditions (12) on \((p,q)\) are optimal for the uniform estimates (14), cf. [35, p.1419]. For any fixed \(\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}\), however, the estimate (13) actually holds for a larger range of exponents, which is due to the improved properties of the Fourier symbol \(1/(|\xi|^2 - \zeta)\) and related Bessel potential estimates. We refer to [35] for more details about sharp \(L^p - L^q\) resolvent estimates of the form (13).

Theorem \(\mathfrak{F}\) extends in an obvious way to the system case that we shall need in the following.

**Corollary 7** (Step 1). Let \(m, n \in \mathbb{N}, n \geq 3\) and assume \(\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}\). Then, for \(1 \leq p, q \leq \infty\) as in (12), \(R_0(\zeta)\) is a bounded linear operator from \(L^p(\mathbb{R}^n; \mathbb{C}^m)\) to \(L^q(\mathbb{R}^n; \mathbb{C}^m)\) satisfying

\[
\|R_0(\zeta)f\|_q \lesssim |\zeta|^{\frac{n+1}{2n}} |\xi|^{\frac{n-1}{2n}} \|f\|_p.
\]

Moreover, there are bounded linear operators \(R_0(\lambda \pm i0) : L^p(\mathbb{R}^n; \mathbb{C}^m) \to L^q(\mathbb{R}^n; \mathbb{C}^m)\) such that \(R_0(\zeta)f \to R_0(\lambda \pm i0)f\) as \(\zeta \to \lambda \pm i0\) for all \(f \in L^p(\mathbb{R}^n; \mathbb{C}^m)\). Furthermore, (14) holds.

### 2.2. Compactness of \(K(\zeta)\)

We first proceed in greater generality by proving the boundedness and compactness of \(K(\zeta)\) as an operator from \(L^q(\mathbb{R}^n; \mathbb{C}^m)\) to \(L^q(\mathbb{R}^n; \mathbb{C}^m)\) for suitable \(q_1, q_2\), as we will use this more general result later. The proof of Step 2 then follows from the particular choice \(q_1 = q_2 = q\), see Corollary \(\mathfrak{F}\) below. In order to simplify the notation in the proofs, we will write \(L^s := L^s(\mathbb{R}^n; \mathbb{C}^m), L^s_{\text{loc}} := L^s_{\text{loc}}(\mathbb{R}^n; \mathbb{C}^m)\), etc.

**Proposition 8.** Let \(n, m \in \mathbb{N}, n \geq 3\) and suppose that \(V \in L^{[\kappa, \kappa]}(\mathbb{R}^n; \mathbb{C}^{m \times m})\) where \(1 \leq \kappa \leq \kappa < \infty\). Then, for \(\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}\) or \(\zeta = \lambda \pm i0, \lambda > 0\), the operator \(K(\zeta) = -R_0(\zeta)V : L^q(\mathbb{R}^n; \mathbb{C}^m) \to L^q(\mathbb{R}^n; \mathbb{C}^m)\) is compact provided that the following conditions hold for \(q_1, q_2 \in [1, \infty)\):

\[
\frac{n+1}{2n} - \frac{1}{\kappa} < \frac{1}{q_1} \leq 1 - \frac{1}{\kappa}, \quad 0 < \frac{1}{q_2} < \frac{n-1}{2n}, \quad \frac{2}{n+1} - \frac{1}{\kappa} \leq \frac{1}{q_1} - \frac{1}{q_2} \leq \frac{2}{n} - \frac{1}{\kappa}.
\]

Moreover,

\[
\|K(\zeta)\|_{q_1 \to q_2} \lesssim \inf_{V = V_1 + V_2} \left( \|\zeta|^{\frac{n+1}{2n}} |\xi|^{\frac{n-1}{2n}} \|V_1\|_{\kappa} + |\zeta|^{\frac{n+1}{2n}} |\xi|^{\frac{n-1}{2n}} \|V_2\|_{\kappa} \right).
\]

Furthermore, \(u_j \to u, \zeta_j \to \zeta\) implies \(K(\zeta_j)u_j \to K(\zeta)u\). In particular, the operators \(K(\zeta)\) depend continuously on \(\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}\) in the uniform operator topology and we have \(K(\zeta) \to K(\lambda \pm i0)\) as \(\zeta \to \lambda \pm i0\).

**Proof.** We begin with proving boundedness of \(K(\zeta) : L^{q_1} \to L^{q_2}\). Using the decomposition \(V = V_1 + V_2, V_1 \in L^{r}(\mathbb{R}^n; \mathbb{C}^{m \times m}), V_2 \in L^{s}(\mathbb{R}^n; \mathbb{C}^{m \times m})\), it follows from Corollary \(\mathfrak{F}\) that

\[
\|K(\zeta)f\|_{q_2} \leq \|R_0(\zeta)f\|_{p \to q_1} \|V_1f\|_p + \|R_0(\zeta)f\|_{\tilde{p} \to q_2} \|V_2f\|_{\tilde{p}}
\]

whenever the tuples \((p, q_1), (\tilde{p}, q_2)\) satisfy the conditions in (12). In view of (15) and \(\kappa \leq \kappa\) these conditions are satisfied if we choose \(p, \tilde{p}\) according to \(\frac{1}{p} = \frac{1}{\kappa} + \frac{1}{m}, \frac{1}{\tilde{p}} = \frac{1}{\kappa} + \frac{1}{q} \). So Hölder’s inequality and Corollary \(\mathfrak{F}\) give

\[
\|K(\zeta)f\|_{q_2} \lesssim \left( |\zeta|^{\frac{n+1}{2n}} |\xi|^{\frac{n-1}{2n}} \|V_1\|_{\kappa} + |\zeta|^{\frac{n+1}{2n}} |\xi|^{\frac{n-1}{2n}} \|V_2\|_{\kappa} \right) \|f\|_{q_1},
\]

which proves the claimed boundedness as well as (17).

Next we show that \(u_j \to u, \zeta_j \to \zeta\) implies \(K(\zeta_j)u_j \to K(\zeta)u\). Here, \(\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}\) or \(\zeta = \lambda \pm i0, \lambda > 0\). Notice that this fact and Corollary \(\mathfrak{F}\) imply the compactness of \(K(\zeta)\) (choose \(\zeta_j := \zeta\)) as well as the existence of a continuous extension of \(\zeta \to K(\zeta)\) in \(B(L^{q_1}; L^{q_2})\) to the closed upper resp. lower complex half-planes.

As shown in [20, Lemma 3.1], without loss of generality, we can assume \(V\) to be bounded and to have compact support.

We first prove \(K(\zeta_j)u_j \to K(\zeta)u\) in \(L^{q_2}_{\text{loc}}\). To this end, it suffices to prove the uniform boundedness of the operators \(K(\zeta_j) : L^{q_1} \to W^{2, q_1}(B; \mathbb{C}^m)\) with respect to \(j\) for any given bounded ball \(B \subset \mathbb{R}^n\). Indeed,
the embedding $W^{2,q}(B;\mathbb{C}^m) \hookrightarrow L^{q_2}(B;\mathbb{C}^m)$ is compact due to $\frac{1}{q_1} - \frac{1}{q_2} \leq \frac{2}{n} - \frac{1}{q} < \frac{2}{n}$ and the Rellich-Kondrachov Theorem, which implies $K(\zeta) u_j \rightarrow v$ in $L^{q_2}(B;\mathbb{C}^m)$ for some $v$. This and $u_j \rightarrow u$ implies $v = K(\zeta)u$. So we conclude $K(\zeta) u_j \rightarrow K(\zeta) u$ in $L^{q_2}_{\text{loc}}$ once we have proved the uniform boundedness of $K(\zeta) : L^{q_1} \rightarrow W^{2,q}(B;\mathbb{C}^m)$.

To prove this let $f \in L^{q_1}$ be arbitrary. Then $u_j := K(\zeta)f$ satisfies the elliptic system

$$\Delta u_j = (\Delta + \zeta_j)u_j - \zeta_j u_j = -Vf - \zeta_j u_j \quad \text{in} \quad 2B.$$  

From elliptic interior regularity estimates and the mapping properties of $K(\zeta)$ stated in Corollary 7 and H"older's inequality we obtain $\|u_j\|_{W^{2,q_2}(B;\mathbb{C}^m)} \lesssim \|f\|_{q_1}$, which is what we had to prove.

To conclude it is sufficient to show $\sup_j \|\chi_{\mathbb{R}^n \setminus B} K(\zeta_j)\|_{q_1 \rightarrow q_2} \rightarrow 0$ as $B \nearrow \mathbb{R}^n$. To this end we use

$$K(\zeta) f(x) = -\int_{\mathbb{R}^n} G_{\zeta_j}(x-y)V(y) f(y) \, dy,$$

where $G_{\zeta_j}(x)$ is the integral kernel of the resolvent operator $R_0(\zeta_j)$, which is explicitly given in terms of Bessel functions. We use the bound $\sup_j |G(\zeta_j)| \lesssim |z|^{-\frac{n+\kappa}{2}}$ for $|z| \geq 1$, see (2.21), (2.25) in [31]. Recalling that $V$ is assumed to be bounded and compactly supported we infer for $M := \sup V$

$$|K(\zeta_j) f(x)| \lesssim \int_M |x-y|^{-\frac{n+\kappa}{2}} |V(y)||f(y)| \, dy \lesssim |x|^{-\frac{n+\kappa}{2}} \|V\|_{q_1} \|f\|_{q_1} \quad \text{if} \quad \text{dist}(x, M) \geq 1.$$  

This yields for large enough balls $B$

$$\|\chi_{\mathbb{R}^n \setminus B} K(\zeta_j)f\|_{q_2} \lesssim \|V\|_{q_1} \|f\|_{q_1} \left(\int_{\mathbb{R}^n \setminus B} |x|^{-\frac{n+\kappa}{2}} \, dx \right)^{\frac{1}{q}}$$

and the conclusion follows due to $q_2 > \frac{2n}{n-1}$.

The second step now results from considering the special case $q_1 = q_2 = q$ in Proposition 8.

**Corollary 9 (Step 2).** Let $n, m \in \mathbb{N}$, $n \geq 3$ and assume that $V \in L^{[\kappa, \tilde{\kappa}]}(\mathbb{R}^n;\mathbb{C}^{m \times m})$ where $\frac{2}{2} \leq \kappa \leq \tilde{\kappa} \leq \frac{n+1}{n}$. Then, for $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ or $\zeta = \lambda \pm i0, \lambda > 0$, the operator $K(\zeta) = -R_0(\zeta)V : L^{q}(\mathbb{R}^n;\mathbb{C}^m) \rightarrow L^{q}(\mathbb{R}^n;\mathbb{C}^m)$ is compact provided that

$$\frac{n+1}{2n} - \frac{1}{\kappa} < \frac{1}{q} < \frac{n-1}{2n}. \quad \text{(17)}$$

Furthermore, $u_j \rightarrow u, \zeta_j \rightarrow \zeta$ implies $K(\zeta_j) u_j \rightarrow K(\zeta) u$. In particular, the operators $K(\zeta)$ depend continuously on $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ in the uniform operator topology and we have $K(\zeta) \rightarrow K(\lambda \pm i0)$ as $\zeta \rightarrow \lambda \pm i0$.

### 2.3. Injectivity of $I - K(\zeta)$

We now prove the injectivity of the Fredholm operator $I - K(\zeta) : L^{q}(\mathbb{R}^n;\mathbb{C}^m) \rightarrow L^{q}(\mathbb{R}^n;\mathbb{C}^m)$ for $q$ as in (17). So we have to show that

$$u - K(\zeta) u = 0, \quad u 

$$

implies $u = 0$. As a starting point, using a bootstrapping procedure, we show that solutions of (18) display both more local integrability and better decay at infinity.

**Proposition 10.** Let $n, m \in \mathbb{N}$, $n \geq 3, q$ as in (17) and assume $V \in L^{[\kappa, \tilde{\kappa}]}(\mathbb{R}^n;\mathbb{C}^{m \times m})$ where $\frac{2}{2} \leq \kappa \leq \tilde{\kappa} \leq \frac{n+1}{n}$. Then any solution $u \in L^{q}(\mathbb{R}^n;\mathbb{C}^m)$ of (18) belongs to

$$L^{r}(\mathbb{R}^n;\mathbb{C}^m) \cap H^{1}_{\text{loc}}(\mathbb{R}^n;\mathbb{C}^m) \quad \text{for all} \quad r \in \left(\frac{2n}{n-1} - \frac{2n}{n-3}, \frac{2n}{n-1}\right) \quad \text{when} \quad \kappa = \frac{n}{2},$$

$$L^{r}(\mathbb{R}^n;\mathbb{C}^m) \cap H^{1}_{\text{loc}}(\mathbb{R}^n;\mathbb{C}^m) \quad \text{for all} \quad r \in \left(\frac{2n}{n-1}, \infty\right) \quad \text{when} \quad \kappa > \frac{n}{2}.$$  

Moreover, for any given such $r, q$ we have $\|u\|_r \lesssim \|u\|_q$. 
Proof. We write again $L^s := L^s(\mathbb{R}^n; \mathbb{C}^m)$. As a starting point we show that any given solution $u \in L^q$ of (18) belongs to $L^r$ for all $r \in (\frac{n}{q} + 1, q)$, in other words $u$ displays a better decay at infinity. We give a proof of this fact distinguishing between $\tilde{\kappa} < \frac{n+1}{2}$ and the limiting case $\tilde{\kappa} = \frac{n+1}{2}$. Let us first consider $\tilde{\kappa} < \frac{n+1}{2}$. Define $\frac{1}{q_0} < \frac{1}{q_1} < \ldots < \frac{1}{q_j} < \frac{1}{q_{j+1}} < \ldots < \frac{1}{2n}$ by

$$\frac{1}{q_j} := \frac{1}{q} \quad \frac{1}{q_{j+1}} := \min \left\{ \frac{1}{2} \left( \frac{1}{q} + \frac{n-1}{2n} \right), \frac{1}{q_j} - \frac{2}{n+1} + \frac{1}{\tilde{\kappa}} \right\} \quad (j \in \mathbb{N}_0).$$

(19)

Since we are assuming $\tilde{\kappa} < \frac{n+1}{2}$, at each iteration we indeed get a smaller Lebesgue exponent, namely $\frac{1}{q_{j+1}} > \frac{1}{q_j}$. Then one shows that the tuple $(q_j, q_{j+1})$ satisfies the conditions (15) in Proposition 8, thus $K(\zeta)$ maps $L^{q_j}$ to $L^{q_{j+1}}$.

Applying iteratively Proposition 8 to the equation (18) we obtain $u \in L^{q_j}$ for all $j \in \mathbb{N}_0$. This can be proved similarly to the limiting case $\tilde{\kappa} = \frac{n+1}{2}$. Let us first consider $\tilde{\kappa} < \frac{n+1}{2}$. Define $\frac{1}{q_0} < \frac{1}{q_1} < \ldots < \frac{1}{q_j} < \frac{1}{q_{j+1}} < \ldots < \frac{1}{2n}$ by

$$\frac{1}{q_0} := \frac{1}{q} \quad \frac{1}{q_{j+1}} := \min \left\{ \frac{1}{2} \left( \frac{1}{q} + \frac{n-1}{2n} \right), \frac{1}{q_j} - \frac{2}{n+1} + \frac{1}{\tilde{\kappa}} \right\} \quad (j \in \mathbb{N}_0).$$

(19)

We use this observation in order to justify a similar iteration as above, this time for exponents $\frac{1}{q_j} < \frac{1}{q_{j+1}} < \ldots < \frac{1}{q_{j+1}} < \ldots < \frac{1}{2n}$ given by

$$\frac{1}{q_0} := \frac{1}{q} \quad \frac{1}{q_{j+1}} := \min \left\{ \frac{1}{2} \left( \frac{1}{q} + \frac{n-1}{2n} \right), \frac{1}{q_j} - \frac{2}{n+1} + \frac{1}{\tilde{\kappa}} \right\} \quad (j \in \mathbb{N}_0).$$

We have to show that $u = K(\zeta)u, u \in L^{q_j}$ implies $u \in L^{q_{j+1}}$. Having done this, we conclude from $\frac{1}{q_j} > \frac{1}{n+1}$ and interpolation that $u \in L^r$ for all $\frac{n+1}{r} < r < q$ as well as $\|u\|_r \lesssim \|u\|_q$, which then finishes the proof of our first claim.

So assume $u \in L^{q_j}$. One can choose $V = V_1 + V_2$ such that

$$C_j \|V_2\|_{\frac{n+1}{q_j}} < \frac{1}{2}$$

(20)

where $C_j$ denotes the operator norm of $R_0(\zeta) : L^{s_j} \rightarrow L^{q_{j+1}}$ where $s_j$ is defined via $\frac{1}{q_j} = \frac{1}{s_j} = \frac{2}{n+1}$. Observe that this operator norm is finite due to Corollary 7 because of $\frac{n+1}{2n} < \frac{1}{s_j} < 1$.

We introduce the auxiliary operator $T := I + R_0(\zeta)V_2 : L^{q_{j+1}} \rightarrow L^{q_{j+1}}$. Using (20) we find that $T$ is bounded and invertible due to Corollary 13. So $T$ has a bounded inverse $T^{-1} : L^{q_{j+1}} \rightarrow L^{q_{j+1}}$. Since $u$ satisfies (18), we have

$$\int_{\mathbb{R}^n} u\phi dx = \int_{\mathbb{R}^n} K(\zeta)u\phi dx = - \int_{\mathbb{R}^n} R_0(\zeta)V_1 u\phi dx - \int_{\mathbb{R}^n} R_0(\zeta)V_2 u\phi dx$$

for any given $\phi \in C_c^\infty(\mathbb{R}^n; \mathbb{C}^m)$. Thus one has

$$\left| \int_{\mathbb{R}^n} T u\phi dx \right| \leq \left| \int_{\mathbb{R}^n} R_0(\zeta)V_1 u\phi dx \right| \leq \|R_0(\zeta)V_1 u\|_{q_{j+1}} \|\phi\|_{q_{j+1}} \lesssim \|u\|_{q_j} \|\phi\|_{q_{j+1}}$$

by Proposition 8. By the the dual characterization of the Lebesgue norms $\| \cdot \|_{q_{j+1}}$ and using density of the test functions in $L^{q_{j+1}}$, one gets $\|Tu\|_{q_{j+1}} \lesssim \|u\|_{q_j}$. Then the boundedness of $T^{-1}$ gives $\|u\|_{q_{j+1}} \lesssim \|u\|_{q_j}$, which is what we had to prove.

Next we prove higher integrability of $u$. In the case $\kappa > \frac{n}{2}$ classical Moser iteration implies $u \in L^\infty$ and the claim follows by interpolation. So it remains to prove $u \in L^r$ for $r \in (q, \frac{2n}{n+1})$ in the limiting case $\kappa = \frac{n}{2}$. This can be proved similarly to the limiting case $\tilde{\kappa} = \frac{n+1}{2}$ above using the decomposition $V = V_1 + V_2$ with $V_1 \in L^{\frac{n}{r+1}}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ and $V_2 \in L^{\frac{n+1}{r}}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ which has a small norm $L^{\frac{n+1}{r}}$. For the sake of brevity we omit the details.
Finally, we discuss the $H^1_{\text{loc}}$-regularity. In the case $\kappa = \frac{n}{2}$ solutions u of \((18)\) satisfy $\Delta u = - (\zeta + V)u$ in $\mathbb{R}^n$ in the distributional sense. Since $\zeta + V \in L^2_{\text{loc}}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ and $u \in L^p_{\text{loc}}(\mathbb{R}^n)$ for all $r < \frac{2n}{n+1}$, we conclude $\Delta u \in L^p_{\text{loc}}(\mathbb{R}^n)$ for all $s \in [1, \frac{2n}{n+1})$. So Caldéron-Zygmund estimates yield $u \in W^{2,s}_{\text{loc}}$ for those exponents and thus $u \in H^1_{\text{loc}}$ by Sobolev’s Embedding Theorem, which finishes the proof for $\kappa = \frac{n}{2}$. In the case $\kappa > \frac{n}{2}$ one obtains similarly $u \in W^{2,k}_{\text{loc}} \subset H^1_{\text{loc}}$ and the proof is finished.

With these improved integrability and regularity properties of solutions at hand, we may turn towards the injectivity of $I - K(\zeta)$. As in the paper by Goldberg and Schlag \cite{GoldbergSchlag}, we will discuss separately the case $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ and the more involved situation $\zeta = \lambda \pm i0, \lambda > 0$. Observe that if $u$ is a solution to \((18)\), then it solves the corresponding eigenvalue equation

\[
(\Delta + \zeta)u + Vu = 0, \quad u \in L^p(\mathbb{R}^n; \mathbb{C}^m).
\]

(22)

To prove injectivity of $I - K(\zeta)$ one is thus lead to prove the absence of embedded eigenvalues for the Schrödinger operator $\Delta + V$. However, for $\zeta = \lambda > 0$, the Helmholtz equation \((22)\) may possess nontrivial solutions: consider for instance $V = 0$ and ordinary Herglotz waves $u$ with pointwise decay rate $|u(x)| \lesssim (1 + |x|)^{(1-n)/2}$. As a consequence, some extra decay condition at infinity coming from the integral representation of $u$ from \((18)\) has to be used in order to deduce $u \equiv 0$. In \cite{GoldbergSchlag} the authors managed to prove that in the case $n = 3, m = 1$ solutions $u \in L^2(\mathbb{R}^3; \mathbb{C})$ of \((18)\) even satisfy $(1 + |\cdot|)^{-\frac{1}{2}}u \in L^2(\mathbb{R}^3; \mathbb{C})$ for some $\tau_1 > 0$ so that a fundamental result by Ionescu-Jerison \cite{IonescuJerison} on the absence of embedded eigenvalues allows to conclude $u \equiv 0$. The ideas presented in \cite{GoldbergSchlag} are not limited to $n = 3$, but carry over to general dimensions $n \geq 2$ in a straightforward manner. In order to avoid redundancy we only state the (scalar) results that generalize Lemma 2.3 and Proposition 2.4 from this paper.

**Proposition 11** (Goldberg-Schlag). Let $n \in \mathbb{N}, n \geq 2$ and assume $f \in L^p(\mathbb{R}^n)$ where $1 \leq p \leq \frac{2(n+1)}{n+3}$. Then we have for $|t| < \frac{1}{2}$ and $\gamma := \frac{1}{2} \min\{1, \frac{n+1}{p} - \frac{n+3}{p}\}$ the estimate

\[
\|f((1 + t)\cdot)a_{L^2(S_k)} \lesssim |t|^\gamma \|f\|_p
\]

provided that $f$ vanishes identically on the unit sphere in $\mathbb{R}^n$.

**Proposition 12** (Goldberg-Schlag). Let $n \in \mathbb{N}, n \geq 2$ and $f \in L^p(\mathbb{R}^n)$ for $\max\{1, \frac{2n}{n+p}\} \leq p \leq \frac{2(n+1)}{n+3}$, $(n,p) \neq (4,1)$. Then we have for all $\tau_1 < \frac{1}{2} \min\{1, \frac{n+1}{p} - \frac{n+3}{p}\}$ the estimate

\[
\|((1 + \cdot)\tau_1^{-\frac{1}{2}}R_{t_0}(\lambda \pm i0) f \|_2 \lesssim \|f\|_p
\]

provided that $f$ vanishes identically on the unit sphere in $\mathbb{R}^n$.

Clearly, Proposition 11 generalizes to systems simply by considering each component separately. This is how we will deduce $(1 + \cdot)^{-\frac{1}{2}}u \in L^2(\mathbb{R}^n; \mathbb{C}^m)$ for some $\tau_1 > 0$, which is crucial for the absence of embedded eigenvalues stated in Theorem 13 below.

To some extent this result is already contained in the work \cite{KochTataru} Theorem 3] by Koch and Tataru. Even so, for the reader’s convenience, we decided to provide a the proof.

**Theorem 13.** Let $n, m \in \mathbb{N}, n \geq 2$, assume $V \in L^p(\mathbb{R}^n; \mathbb{C}^{m \times m})$ and let $u \in H^1_{\text{loc}}(\mathbb{R}^n; \mathbb{C}^m)$ be a solution of \((22)\) for $\zeta \in \mathbb{R}_{>0}$ satisfying $|x|^{-1}u \in L^2(\mathbb{R}^n; \mathbb{C}^m)$. Then $u \equiv 0$.

**Proof.** The key point is the $L^p$-Carleman estimate proved in \cite{KochTataru}. More precisely, introducing the Carleman weight $h_\epsilon(t)$ such that $h_\epsilon(t) = (\zeta + V) - (\tau \epsilon + \tau_1)\tau_0^{2x + \epsilon}$, $\epsilon > 0$, Koch and Tataru proved in \cite{KochTataru} Proposition 4]

\[
\|e^{h_\epsilon(\ln|\cdot|)} v \|_{L^p} + \|e^{h_\epsilon(\ln|\cdot|)} v \|_{L^{p+\epsilon}(\mathbb{R}^n; \mathbb{C}^{m \times m})} \lesssim \inf_{(\Delta + \zeta) = f + g} \|e^{h_\epsilon(\ln|\cdot|)} f \|_{L^p} + \|h_\epsilon(\ln|\cdot|) g \|_{L^{p+\epsilon}(\mathbb{R}^n; \mathbb{C}^{m \times m})}
\]

(23)

for all $v$ supported in $\mathbb{R}^n \setminus B_1$ such that $|x|^{-\frac{1}{2}}v \in L^2(\mathbb{R}^n)$. Notice that \((23)\) is uniform with respect to $0 < \epsilon \leq \epsilon_0$ and $\tau_0 \geq \tau_0 > 0$ for some $\epsilon_0, \tau_0 > 0$. Notice that in \cite{KochTataru} the estimate \((23)\) is proved even for more general classes of Helmholtz-type operators also allowing for long-range perturbations. Moreover, the
corresponding estimate (7) in that paper is formulated with even stronger norms on the left and weaker norms on the right, as one can check using the embeddings
\[
L^{\frac{2(n+1)}{n+3}}(\mathbb{R}^n) + L^{\frac{2(n+1)}{n+5}}(\mathbb{R}^n) \hookrightarrow W^{-\frac{4(n+1)}{n+7}}(\mathbb{R}^n), \quad L^{\frac{2(n+1)}{n+3}}(\mathbb{R}^n) \cap L^{\frac{2(n+1)}{n+5}}(\mathbb{R}^n) \hookrightarrow W^{-\frac{4(n+1)}{n+7}}(\mathbb{R}^n).
\]

(24)

**Step 3.1: Exponential decay.** As anticipated we first show that \( u \) decays at infinity faster than \( e^{-\tau|x|^{1/2}} \) in some integrated sense. In order to apply (23) for this purpose, we need to localize the support of \( u \) to a spatial region far from the origin. So we pick a non-negative bump function \( \phi \in C^\infty(\mathbb{R}^n) \) such that \( \phi(x) = 1 \) for \( |x| > 2R \) and \( \phi(x) = 0 \) for \( |x| \leq R \) for a sufficiently large \( R \) to be chosen later and define \( v := \phi u \). Then \( v \) solves
\[
(\Delta + \zeta)v = (\Delta \phi)u + 2\nabla \phi \cdot \nabla u + V_1v + V_2v.
\]

Now we apply the scalar Carleman estimate (23) to each component of the system. Summing up the resulting estimates one gets
\[
\|e^{h_r(\ln |x|)\nu}|\|_{L^{\frac{2(n+1)}{n+7}}} + \|e^{h_r(\ln |x|)\nu}|\|_{L^{\frac{2(n+1)}{n+9}}} \lesssim \|e^{h_r(\ln |x|)\nu}|\|_{L^{\frac{2(n+1)}{n+7}}} + \|e^{h_r(\ln |x|)\nu}|\|_{L^{\frac{2(n+1)}{n+9}}}.
\]

Step 3.2: Compact support. From (23) we even infer that \( u \) is supported in \( \overline{B_{2R}} \setminus B_R \). Indeed, \( |x|^{1/2} \leq \sqrt{2R} \) on \( B_{2R} \setminus B_R \) implies
\[
e^{-\tau\sqrt{2R}}\left(\|e^{\tau|x|^{1/2}}\|_{L^{\frac{2(n+1)}{n+7}}} + \|e^{\tau|x|^{1/2}}\|_{L^{\frac{2(n+1)}{n+9}}} \right) \lesssim \|e^{\tau|x|^{1/2}}\|_{L^{\frac{2(n+1)}{n+7}}} + \|e^{\tau|x|^{1/2}}\|_{L^{\frac{2(n+1)}{n+9}}}.
\]

Letting \( \tau \) go to infinity shows that \( v \) and hence \( u \) have exponential decay at infinity.

**Step 3.3: Triviality.** In virtue of the conclusions provided by Step 3.2, proving the triviality of \( u \) reduces to proving the weak unique continuation property for the differential inequality \( |\Delta u| \leq |V||u| \). At this stage we only need that our potential \( V \in L^{\frac{2(n+1)}{n+3}}(\mathbb{R}^n; C^m) \) belongs to \( L^{\frac{2(n+1)}{n+3}}(\mathbb{R}^n; C^m) \), as only local properties of the solution \( u \) are investigated. So [28] Theorem 6.3] applies and we obtain \( u \equiv 0 \). \( \square \)

Now we are in the position to prove the injectivity of \( I - K(\zeta) \).
Corollary 14 (Step 3). Let $n, m \in \mathbb{N}$, $n \geq 3$ and assume $V = \nabla^T \in L^{[\kappa, \tilde{\kappa}]}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ where $\frac{d}{2} \leq \kappa \leq \tilde{\kappa} \leq \frac{n+1}{2}$. Then, for $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ or $\zeta = \lambda \pm i0, \lambda > 0$, the operator $I - K(\zeta) : L^q(\mathbb{R}^n; \mathbb{C}^m) \to L^q(\mathbb{R}^n; \mathbb{C}^m)$ is bijective and satisfies

$$
\|(I - K(\zeta))^{-1}\|_{q \to q} \leq C < \infty \quad \text{for all } \zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}
$$

provided that $q$ satisfies \(17\). Moreover, $\zeta \mapsto (I - K(\zeta))^{-1}$ is continuous on $\mathbb{C} \setminus \mathbb{R}_{\geq 0}$ and we have $(I - K(\zeta))^{-1} \to (I - K(\lambda \pm i0))^{-1}$ in the uniform operator topology as $\zeta \to \lambda, \text{Im}(\zeta) \to 0^\pm$.

Proof. Once again we write $L^s := L^s(\mathbb{R}^n; \mathbb{C}^m)$. We only consider the case $\zeta = \lambda \pm i0, \lambda > 0$ since the remaining case $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ is straightforward and can be handled as in equation (3.6) in [20]. We first prove that the operator is injective, so our aim is to show that any given solution $u$ of \(13\) must be trivial.

Proposition \(10\) implies $u \in L'$ whenever $\frac{n-3}{2n} < \frac{1}{p} < \frac{n+3}{2n}$. So $V \in L^{[\kappa, \tilde{\kappa}]}(\mathbb{R}^n; \mathbb{C}^{m \times m}) \subseteq L^{[\frac{2(n+1)}{n+3}, \frac{2}{n}]}(\mathbb{R}^n; \mathbb{C}^{m \times m})$ implies $Vu \in L^{[p_1, p_2]}(\mathbb{R}^n; \mathbb{C}^m)$ for some $p_1, p_2$ satisfying

$$
\frac{2}{n} + \frac{n-3}{2n} < \frac{1}{p_1} < \frac{2}{n} + \frac{n-1}{2n}, \quad \frac{2}{n+1} + \frac{n-3}{2n} < \frac{1}{p_2} < \frac{2}{n+1} + \frac{n-1}{2n}.
$$

This implies $Vu \in L^p$ where $\frac{2}{n} + \frac{n-3}{2n} < \frac{1}{p} < \frac{2}{n+1} + \frac{n-1}{2n}$. In particular, we deduce from $u \in L'$ for $\frac{n-3}{2n} < \frac{1}{r} < \frac{n-1}{2n}$ the statement

$$
u \in L^p, \quad g := Vu \in L^p \quad \text{whenever} \quad \frac{n+1}{2n} < \frac{1}{p} < \frac{n^2 + 4n - 1}{2n(n+1)}.
$$

So a density argument and $V = \nabla^T$ imply

$$
0 = \text{Im} (\langle u, Vu \rangle) = \text{Im} (\langle (K(\lambda + i0)u, g) \rangle) = -c\sqrt{|\lambda|} \int_{S_0} |\hat{g}(\sqrt{|\lambda|})|^2 d\sigma(\omega) \quad (26)
$$

for some positive number $c > 0$, cf. (3.7) in [20]. This implies that $\hat{g}$ vanishes identically on the sphere of radius $\sqrt{|\lambda|}$ so that Proposition \(12\) (choose $\lambda = \frac{2(n+1)}{n+3}$) implies

$$(1 + |\cdot|)^{\tau_1 - \frac{2}{p}} u = (1 + |\cdot|)^{\tau_1 - \frac{2}{p}} K(\lambda + i0)u = -(1 + |\cdot|)^{\tau_1 - \frac{2}{p}} R_0(\lambda + i0)g \in L^2
$$

provided that $0 < \tau_1 < \frac{1}{2} \min\{1, \frac{n+1}{p} - \frac{n-3}{2n}\}$. In view of $u \in H^1_{loc}$, which is a consequence of Proposition \(10\), we see that the hypotheses of Theorem \(13\) are satisfied and we conclude $u \equiv 0$, which proves the injectivity of $I - K(\zeta)$ and hence its invertibility.

To prove the continuity of $\zeta \mapsto (I - K(\zeta))^{-1}$ from $\mathbb{C} \setminus \mathbb{R}_{\geq 0}$ to the space $B(L^2; L^2)$ we use the identity

$$(I - K(\zeta))^{-1} - (I - K(\zeta))^{-1} = (I - K(\zeta))^{-1}(K(\zeta) - K(\zeta))(I - K(\zeta))^{-1} \quad (27)
$$

for $\zeta_1, \zeta_2 \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$. Hence, for all $\zeta_1, \zeta_2$ belonging to $A \setminus \mathbb{R}$ and compact sets $A \subset \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ we have

$$
\|(I - K(\zeta))^{-1} - (I - K(\zeta_2))^{-1}\|_{q \to q} \leq \|K(\zeta) - K(\zeta_2)\|_{q \to q}.
$$

Here we used that the operator norms of $(I - K(\zeta_1))^{-1}, (I - K(\zeta_2))^{-1}$ are uniformly bounded on $A$. Hence, the continuity of $K$ and \(27\) imply the continuity of $\zeta \mapsto (I - K(\zeta))^{-1}$. In the same way, the existence of a continuous extension of $\zeta \mapsto K(\zeta)$ to the positive half-axis in the operator norm topology provided by Corollary \(9\) implies the existence of a continuous extension of $\zeta \mapsto (I - K(\zeta))^{-1}$ in the operator norm topology. This and Theorem \(3\) finally imply that $\zeta \mapsto R(\zeta) = (I - K(\zeta))^{-1} R_0(\zeta)$ is pointwise convergent as $\zeta \to \lambda \pm i0, \lambda > 0$ as claimed in Theorem \(3\).

Finally, using a decomposition of $V$ as in Proposition \(10\) with small $L^2$-part, the bound \(10\) from Proposition \(5\) implies

$$
\|K(\zeta)\|_{q \to q} \leq c + C_\varepsilon |\zeta|^{-\frac{n+1}{n+3}}
$$

for all $\varepsilon > 0, \zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ and some $C_\varepsilon > 0$. In particular, the norms of these operators tend to zero as $|\zeta| \to \infty$. Thus, one can choose sufficiently large $R$ and sufficiently small $\varepsilon$ such that $\|K(\zeta)\|_{q \to q} < \frac{1}{2}$ provided that $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ and $|\zeta| \geq R$. So the Neumann series expansion for $|\zeta| \geq R$ and the uniform boundedness for $|\zeta| < R$ show that $\|(I - K(\zeta))^{-1}\| \leq C < \infty$ for all $\zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0}$ and the claim is proved. \(\square\)
Remark 15. For a better understanding of the forthcoming sections, we stress here that the hypothesis of $V$ being Hermitian is crucial in the proof of the injectivity, thus invertibility, of $I - K(\zeta)$. Indeed, the vanishing of $\hat{g}$ on the sphere of radius $\sqrt{\lambda}$, which is a fundamental step in the proof, strongly relies on the identity $\text{Im}(\langle u, Vu \rangle) = 0$, see [20] of Appendix A.

3. ABSENCE OF EIGENVALUES FOR MAXWELL’S EQUATIONS – PROOF OF THEOREM 3

In this section we prove Theorem 3. To this end we rewrite the time-harmonic Maxwell system (1) as a linear Helmholtz system without first order terms so that the result essentially follows from Theorem 13. To write down this Helmholtz system we introduce some notation. For any given $\varepsilon, \mu$ as in (A1),(A2) and $\zeta \in \mathbb{C}$ we define the $6 \times 6$ complex-valued block matrices/operators

$$V(\zeta) := \begin{pmatrix} V_1(\zeta) & -i\zeta \nabla \times V_2(\zeta) \\ i\zeta \nabla \times V_2(\zeta)^\dagger & V_1(\zeta) \end{pmatrix}, \quad \mathcal{L}_1(\zeta) := \begin{pmatrix} i\zeta (\varepsilon \mu)^{\frac{3}{2}} I_3 & -\frac{i}{2} \nabla(\log \varepsilon) \times \\ -\frac{i}{2} \nabla(\log \mu) \times & -i\zeta (\varepsilon \mu)^{\frac{3}{2}} I_3 \end{pmatrix}, \quad \mathcal{L}_2 := \begin{pmatrix} 0 & -\nabla \times \\ -\nabla \times & 0 \end{pmatrix}. \quad (28)$$

Here, $v := 2\nabla((\varepsilon \mu)^{\frac{3}{2}}) : \mathbb{R}^3 \to \mathbb{R}^3$ and $V_1(\zeta), V_2(\zeta) : \mathbb{R}^3 \to \mathbb{C}^{3 \times 3}$ are given by

$$V_1(\zeta) := -\varepsilon^{\frac{1}{2}} \Delta(\varepsilon^{\frac{1}{2}}) I_3 + \nabla \nabla^T(\log \varepsilon) - \zeta^2(\varepsilon \mu \varepsilon \mu^{-1} - \varepsilon \mu) I_3,$$

$$V_2(\zeta) := -\mu^{\frac{1}{2}} \Delta(\mu^{\frac{1}{2}}) I_3 + \nabla \nabla^T(\log \mu) - \zeta^2(\varepsilon \mu \varepsilon \mu^{-1} - \varepsilon \mu) I_3. \quad (29)$$

In the following Lemma we show that solutions of the time-harmonic Maxwell system give rise to solutions of a $6 \times 6$ Helmholtz system with complex-valued coefficients given by (28), (29). The proof, which is purely computational, can be found in Appendix A.

Lemma 16. Assume (A1), $\zeta \in \mathbb{C}$ and let $J_e, J_m \in L^2_{\text{loc}}(\mathbb{R}^3;\mathbb{C}^3)$ be divergence-free. Then every weak solution $(E, H) \in H^1_{\text{loc}}(\mathbb{R}^3;\mathbb{C}^6)$ of the time-harmonic Maxwell system (1) satisfies

$$(\Delta + \varepsilon \mu \varepsilon \mu^{-1} - \varepsilon \mu) \left( \begin{pmatrix} \hat{E} \\ \hat{H} \end{pmatrix} \right) + V(\zeta) \left( \begin{pmatrix} \hat{E} \\ \hat{H} \end{pmatrix} \right) = \mathcal{L}_1(\zeta) \left( \begin{pmatrix} J_e \\ J_m \end{pmatrix} \right) + \mathcal{L}_2 \left( \begin{pmatrix} J_e \\ J_m \end{pmatrix} \right) \quad \text{in } \mathbb{R}^3 \quad (30)$$

in the weak sense where $(\hat{E}, \hat{H}) := (\varepsilon \mu \hat{E}, \mu \hat{H})$ and $(J_e, J_m) := (\mu^{\frac{1}{2}} J_e, \mu^{\frac{1}{2}} J_m)$.

Remark 17. Lemma 16 allows to deduce further properties of solutions of time-harmonic Maxwell’s equations from the corresponding theory for elliptic PDEs. For instance, one may deduce local regularity properties as we will do in Proposition 19. We refer to [4] Section 3 for other approaches to regularity results for time-harmonic Maxwell’s equations. Further features such as Harnack inequalities or maximum principles can be proved as well. Our assumptions on the data $\varepsilon, \mu$ may however be far from optimal.

Proof of Theorem 3: Let $(E, H) \in H^1_{\text{loc}}(\mathbb{R}^3;\mathbb{C}^6)$ be a weak solution of the homogeneous $(J_e = J_m = 0)$ time-harmonic Maxwell system (1) for $\zeta \in \mathbb{C}$ and assume $(1 + |x|)^{\tau_1 - \frac{1}{2}}(|E| + |H|) \in L^2(\mathbb{R}^3)$ for some $\tau_1 > 0$. From (1) we infer $(1 + |x|)^{\tau_1 - \frac{1}{2}}(|\nabla \times E| + |\nabla \times H|) \in L^2(\mathbb{R}^3)$ as well as

$$\int_{\mathbb{R}^3} \frac{1}{\mu} (\nabla \times E) \cdot (\nabla \times \phi) \, dx = \zeta^2 \int_{\mathbb{R}^3} \varepsilon \mu \phi \quad \text{for all } \phi \in C^\infty_c(\mathbb{R}^3;\mathbb{C}^3).$$

By density of test functions and $E \in H^1_{\text{loc}}(\mathbb{R}^3;\mathbb{C}^6)$ we obtain $(\phi = \varepsilon \hat{E})$

$$\int_{\mathbb{R}^3} \frac{1}{\mu} (\nabla \times E)^2 \chi \, dx + \int_{\mathbb{R}^3} \frac{1}{\mu} (\nabla \times E) \cdot (\nabla \chi \times \varepsilon \hat{E}) \, dx = \zeta^2 \int_{\mathbb{R}^3} \varepsilon |E|^2 \chi \, dx \quad \text{for all } \chi \in C^\infty_c(\mathbb{R}^3). \quad (31)$$

We choose $\chi = \chi^*(R) / R$ where $\chi^* \in C^\infty(\mathbb{R}^3)$ is a real-valued radially nonincreasing nonnegative function that is identically one near the origin so that $\chi^*(R) \sim 1$ as $R \to \infty$. Using $|\nabla \chi^*(R)| \lesssim (1 + |R|)^{-1}$ we get for $R \geq 1$

$$\int_{\mathbb{R}^3} \frac{1}{\mu} (\nabla \times E) \cdot (\nabla \chi \times \varepsilon \hat{E}) \, dx \lesssim R^{-1} \int_{\mathbb{R}^3} |\nabla \times E| \, dx \quad \text{for all } \chi \in C^\infty_c(\mathbb{R}^3).$$
In other words, the second integral in \(31\) vanishes as \(R \to \infty\).

From this we conclude as follows. In the case \(\text{Im}(\zeta^2) \neq 0\) we take the imaginary part of \(31\) and get from the Monotone Convergence Theorem \(\int_{\mathbb{R}^3} |E|^2 = 0\), hence \(E = 0\). In the case \(\text{Re}(\zeta^2) \leq 0\) we take the real part of \(31\) and obtain \(\int_{\mathbb{R}^3} \frac{1}{\mu} |\nabla \times E|^2 - \text{Re}(\zeta^2)|E|^2 = 0\). Again, \(E = 0\). So we have \(E = 0\) in both cases, which then implies \(H = 0\) because of \(1\). This proves the absence of eigenvalues for all \(\zeta \in \mathbb{C} \setminus \mathbb{R} \cup \{0\}\).

We now prove the claim for \(\zeta \in \mathbb{R} \setminus \{0\}\). We deduce from Lemma \(14\) that \((\hat{E}, \hat{H}) \in H^1_{loc}(\mathbb{R}^3; \mathbb{C}^6)\) is a weak solution of the Helmholtz system \(30\) for \(J = J_m = 0\). After decomposing \(\hat{E}, \hat{H}\) and the coefficient matrix \(V(\zeta)\) into real and imaginary part, we find that \(u := (\text{Re}(\hat{E}), \text{Re}(\hat{H}), \text{Im}(\hat{E}), \text{Im}(\hat{H}))\) is a weak solution in \(H^1_{loc}(\mathbb{R}^3; \mathbb{R}^{12})\) of a real \((12 \times 12)\)-Helmholtz system of the form \((\Delta + \lambda)u + V u = 0\) in \(\mathbb{R}^3\) where \(\lambda = \zeta^2 \varepsilon_{\infty} \mu_{\infty}\) and \(V \in L^{\frac{3}{2}}(\mathbb{R}^3; \mathbb{R}^{12 \times 12})\). The latter is a consequence of \(A2\). Since our assumptions imply \((1 + |x|)^{\tau_1 - \frac{3}{2}} u \in L^2(\mathbb{R}^3; \mathbb{R}^{12})\) and \(\lambda = \zeta^2 \varepsilon_{\infty} \mu_{\infty} > 0\), Theorem \(13\) yields \(u \equiv 0\) and thus \(E \equiv H \equiv 0\). This finishes the proof. \(\square\)

Remark 18. In the proof of Theorem \(13\) we used two different approaches to treat the cases \(\zeta \in \mathbb{C} \setminus \mathbb{R} \cup \{0\}\) and \(\zeta \in \mathbb{R} \setminus \{0\}\). As a matter of fact, we cannot deduce the absence of eigenvalues \(\zeta \in \mathbb{C} \setminus \mathbb{R}\) by a reduction to the Helmholtz-type system \(30\) as in the case \(\zeta \in \mathbb{R} \setminus \{0\}\). Indeed, as soon as we allow \(\text{Im}(\lambda) \neq 0\) (recall that \(\lambda = \zeta^2 \varepsilon_{\infty} \mu_{\infty}\)), the function \(u := (\text{Re}(\hat{E}), \text{Re}(\hat{H}), \text{Im}(\hat{E}), \text{Im}(\hat{H}))\) satisfies \((\Delta + \text{Re}(\lambda))u + W u + V u = 0\), where \(W\) is a constant-valued \(12 \times 12\)-matrix given by

\[
W = \begin{pmatrix}
0 & \text{Im}(\lambda)I_6 \\
-\text{Im}(\lambda)I_6 & 0
\end{pmatrix}.
\]

The lack of decay of \(W\) rules out the possibility of applying Theorem \(13\) and as a consequence one cannot conclude \(u \equiv 0\). So the difficulty of treating complex-valued potentials cannot be resolved just by taking the real and imaginary parts of the equation. On the contrary, as we will see in the next section, the treatment of complex-valued potentials requires a more accurate analysis of the problem.

4. The LAP for Maxwell’s equations – Proof of Theorem \(1\)

This section is devoted to the proof of the Limiting Absorption Principle for the time-harmonic Maxwell system \(1\) stated in Theorem \(1\). We shall first give an overview of the main steps of the proof, the rigorous details are provided afterwards. We start by considering \((E_\zeta, H_\zeta) \in H^1(\mathbb{R}^3; \mathbb{C}^6)\), the uniquely determined solutions of the approximating time-harmonic Maxwell system

\[
i \zeta \varepsilon E_\zeta - \nabla \times H_\zeta = -J_\zeta^\epsilon, \quad i \zeta \mu H_\zeta + \nabla \times E_\zeta = J_\zeta^\mu,
\]

where \(\zeta \in \mathbb{C} \setminus \mathbb{R}\) and \(J_\zeta^\epsilon, J_\zeta^\mu \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^\infty(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3)\) are divergence-free currents that approximate the given divergence-free currents \(J_{\epsilon, m} \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^\infty(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3)\) as \(\zeta \to \omega \in \mathbb{R}_{>0}\). The necessity of introducing the approximating problem \(32\) with square integrable currents \((J_\zeta^\epsilon, J_\zeta^\mu)\) comes from the fact that, up to our knowledge, the existence and uniqueness of solutions to the time-harmonic Maxwell system \(1\) for general divergence-free currents \((J_\epsilon, J_m) \in L^p(\mathbb{R}^3; \mathbb{C}^6) \cap L^\infty(\mathbb{R}^3; \mathbb{C}^6)\) are not known. In our analysis we will use the results and notation of the previous sections, notably \(V(\zeta), \mathcal{L}_1(\zeta), \mathcal{L}_2, V_1(\zeta), V_2(\zeta)\) and the vector field

\[
v = 2\nabla((\varepsilon \mu)^\frac{1}{2})
\]
Thus the injectivity estimate (36), (42) yields
\[ u_\zeta := (\tilde{E}_\zeta, \tilde{H}_\zeta) := (e^{\frac{i}{\varepsilon}}E_\zeta, \mu e^{\frac{i}{\varepsilon}}H_\zeta) \] (33)
are solutions of the Helmholtz system
\[ (\Delta + \zeta^2 \varepsilon \mu \omega^2)u_\zeta + \mathcal{V}(\zeta)u_\zeta = \mathcal{L}_1(\zeta)\tilde{J}_\zeta + \mathcal{L}_2\tilde{J}_\zeta, \] (34)
where \( \mathcal{V}(\zeta) \), \( \mathcal{L}_1(\zeta) \) and \( \mathcal{L}_2 \) are defined in (23) and \( \tilde{J}_\zeta = (\tilde{J}_\zeta^1, \tilde{J}_\zeta^2) := (\mu e^{\frac{i}{\varepsilon}}J_\zeta, e^{\frac{i}{\varepsilon}}J_\zeta^1) \). Due to the explicit relation between the spectral parameters in the Maxwell and Helmholtz systems, the limiting case \( \zeta = \omega \pm i\theta, \omega \in \mathbb{R} \setminus \{0\} \) in the Maxwell system corresponds to the limiting case in the Helmholtz system \( \zeta = \lambda \pm \text{sign}(\omega)i\theta \), \( \lambda = \omega^2 \varepsilon \mu \omega^2 > 0 \). The boundedness assumption on \( \varepsilon, \mu \) from (A1) implies that, as soon as we are able to provide a uniform bound of \( \|u_\zeta\|_q \) as \( |\text{Im}(\zeta)| \to 0 \), a corresponding bound also holds true for \( \|(E_\zeta, H_\zeta)\|_q \).

In order to prove such bounds for \( \|u_\zeta\|_q \) we need to investigate the vectorial Helmholtz type operators \( \Delta + \zeta^2 \varepsilon \mu \omega^2 I_m + \mathcal{V}(\zeta) \), that may we rewrite as \( (\Delta + \zeta^2 \varepsilon \mu \omega^2)(I - \mathcal{K}(\zeta)) \) where
\[ \mathcal{K}(\zeta) := (\Delta + \zeta^2 \varepsilon \mu \omega^2)\mathcal{V}(\zeta) \quad (\zeta \in \mathbb{C} \setminus \mathbb{R}) \]
and \( (\omega \pm i\theta)^2 \varepsilon \mu \omega^2 := \omega^2 \varepsilon \mu \omega^2 \pm \text{sign}(\omega)i\theta \). Since the potential \( \mathcal{V}(\zeta) \) is in general not Hermitian (see (28)), not even for \( \zeta = \omega \pm i\theta, \omega \in \mathbb{R} \setminus \{0\} \), we cannot verify the sufficient condition \( \text{Im}(u, \mathcal{V}(\zeta)u) = 0 \) for the bijectivity of \( I - \mathcal{K}(\zeta) \), see the proof of Corollary 14 and Remark 15. Nevertheless, in Proposition 21 we will quantify the potential lack of injectivity of the operator \( I - \mathcal{K}(\zeta) \) through the following injectivity estimates
\[ \|u\|_{q_1} + \|u\|_{q_2} \lesssim \|(I - \mathcal{K}(\zeta))u\|_{q_1} + \|((I - \mathcal{K}(\zeta))u)_{\text{sign}(\omega)i\theta}) + \|\text{Im}(u, \mathcal{V}(\zeta)u)|_{\text{sign}(\omega)i\theta} \|^{1/2} \] (36)
for all \( u = (u_{\varepsilon}, u_{m}) \in L^q(\mathbb{R}^3; \mathbb{C}^6) \cap L^p(\mathbb{R}^3; \mathbb{C}^6), \) and \( |\text{Re}(\zeta)| \geq \delta > 0 \). We remark that it is for proving (36) that the additional integrability assumptions from (A3) enter the proof of Theorem 1.

The estimate (36) is valid for any \( u = (u_{\varepsilon}, u_{m}) \in L^q(\mathbb{R}^3; \mathbb{C}^6), \) no matter whether \( u \) is a solution of the Helmholtz system (34) or not. On the other hand, if we consider the family \( u_\zeta \) of solutions to (31) defined in (35), the following representation formula in terms of the resolvent \( R_0 \) of the Laplacian is available
\[ (I - \mathcal{K}(\zeta))u_\zeta = R_0(\zeta^2 \varepsilon \mu \omega^2)[\mathcal{L}_1(\zeta)\tilde{J}_\zeta + \mathcal{L}_2\tilde{J}_\zeta]. \] (37)
Thus the injectivity estimate (36), (32) yields
\[ \|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2} \lesssim \|R_0(\zeta^2 \varepsilon \mu \omega^2)[\mathcal{L}_1(\zeta)\tilde{J}_\zeta + \mathcal{L}_2\tilde{J}_\zeta]\|_{q_1} + \|R_0(\zeta^2 \varepsilon \mu \omega^2)[\mathcal{L}_1(\zeta)\tilde{J}_\zeta + \mathcal{L}_2\tilde{J}_\zeta]\|_{q_2} \]
\[ + \|\text{Im}(u, \mathcal{V}(\zeta)u)|_{\text{sign}(\omega)i\theta} \|^{1/2} \] (38)
As soon as (38) is proved, the final step will be to bound the right-hand side of (38) in terms of \( \|J\|_p + \|J\|_p \) and other terms depending on \( \|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2} \) that become negligible as \( \zeta \to \omega \pm i\theta \). Estimating the first two terms only requires minor modifications of Corollary 14 and it is explicitly performed in Proposition 27. On the other hand, in order to estimate the third term, the structure of Maxwell’s equations (32) comes into play. Indeed, in order to get the claimed bound, we shall not only make use of the explicit expression of \( u_\zeta \) in terms of \( (E_\zeta, H_\zeta) \) from (35), but also that \( (E_\zeta, H_\zeta) \) solves Maxwell’s equations (32). Combining the previous steps one gets the following uniform estimate
\[ \|E_\zeta\|_q + \|H_\zeta\|_q \lesssim \|J\|_p + \|J\|_p + o(1) \quad \text{as } \zeta \to \omega \pm i\theta. \] (39)
From (35), in a rather standard way (see Subsection 4.3), one obtains the Limiting Absorption Principle contained in Theorem 1.
In the following $p, \tilde{p}, q, q_1, q_2$ are chosen as in Theorem 1. We will use the notation from [28] and [29]. In the proofs we will write $L^r := L^r(\mathbb{R}^3; C^0)$ and similarly for $W^{1,r}, L^r_{loc}$ etc.

4.1. Injectivity estimates. First we recall from Proposition 10 (with $\kappa = \frac{3}{2} = \frac{3}{3}, \tilde{\kappa} = \frac{n+1}{2} = 2$) the regularity and integrability properties of $L^3(\mathbb{R}^3; C^0)$-solutions to $(I - \mathcal{K}(\zeta))u = 0$. Using the definitions [28], [29] and assumption (A2) we get the following result.

**Proposition 19.** Assume (A2) and let $q$ satisfy $3 < q < 6$. Moreover assume $(I - \mathcal{K}(\zeta))u = 0$ for some $u \in L^q(\mathbb{R}^3; C^0)$ where $\zeta \in \mathbb{C} \backslash \mathbb{R}$ or $\zeta = \omega \pm i0, \omega \in \mathbb{R} \backslash \{0\}$. Then any solution $u \in L^q(\mathbb{R}^3; C^0)$ of $(I - \mathcal{K}(\zeta))u = 0$ belongs to $L^r(\mathbb{R}^3; C^0) \cap H^s_{loc}(\mathbb{R}^3; C^0)$ for all $r \in (3, \infty)$. Moreover, for any given such $r, q$ we have $\|u\|_r \leq \|u\|_q$.

As in the Helmholtz case these integrability properties are actually better for $\zeta \in \mathbb{C} \backslash \mathbb{R}$ where we even have $u \in H^1(\mathbb{R}^3; C^0)$. Next we present the crucial scalar condition ensuring the injectivity of $I - \mathcal{K}(\zeta) = I + R_0(\zeta^2 \varepsilon_{\infty} \mu_{\infty})|\mathcal{V}(\zeta)|$. It comes as no surprise that the condition to guarantee injectivity only involves $\text{Im}(\langle u, \mathcal{V}(\zeta)u \rangle)$. It can be seen as an isotropic inhomogeneous variant of the Silver-Müller type radiation condition, which, roughly speaking, represents the analogue for Maxwell equations of the well-known Sommerfeld radiation conditions in the context of Helmholtz equations.

**Proposition 20.** Let (A2) hold and assume $3 < q < 6$. Moreover assume $(I - \mathcal{K}(\zeta))u = 0$ for some $u = (u_e, u_m) \in L^q(\mathbb{R}^3; C^0)$ where $\zeta \in \mathbb{C}$ with $\mathcal{V}(\zeta^2) \neq 0$ or $\zeta = \omega \pm i0, \omega \in \mathbb{R} \backslash \{0\}$. Then

$$\text{Im}(\langle u, \mathcal{V}(\zeta)u \rangle) \iff u = 0.$$  

**Proof.** We only need to prove the implication “$\implies$”, so we assume that $\text{Im}(\langle u, \mathcal{V}(\zeta)u \rangle) = 0$. This implies

$$0 = \text{Im} \left( \int_{\mathbb{R}^3} \bar{\mathcal{V}}(\zeta)u \, dx \right) = \text{Im} \left( \int_{\mathbb{R}^3} \mathcal{K}(\zeta)u \cdot \mathcal{V}(\zeta)u \, dx \right) \overset{35}{=} - \text{Im} \left( \int_{\mathbb{R}^3} R_0(\zeta^2 \varepsilon_{\infty} \mu_{\infty})|\mathcal{V}(\zeta)|u \cdot \mathcal{V}(\zeta)u \, dx \right).$$

For $\mathcal{V}(\zeta^2) \neq 0$ we deduce as in equation (3.6) of [20] that $\mathcal{V}(\zeta)u \equiv 0$ and hence $u \equiv \mathcal{K}(\zeta)u \equiv 0$ by [35]. In the case $\zeta = \omega \pm i0, \omega \in \mathbb{R} \backslash \{0\}$ we get as in the proof of Corollary 13 for $\lambda = \omega^2 \varepsilon_{\infty} \mu_{\infty} > 0$

$$0 = \text{Im} \left( \int_{\mathbb{R}^3} \mathcal{K}(\omega \pm i0)u \cdot \mathcal{V}(\omega)u \right) = - \text{Im} \left( \int_{\mathbb{R}^3} R_0(\lambda \pm \text{sign}(\omega) i0)|\mathcal{V}(\omega)|u \cdot \mathcal{V}(\omega)u \right)$$

$$= \mp \text{sign}(\omega) \int_{S_\lambda} |\mathcal{V}(\omega)u|^2 \, d\sigma,$$

for some $c \neq 0$. Hence, $\hat{\mathcal{V}(\omega)}u = 0$ on $S_\lambda$ in the $L^2$-trace sense. Moreover, $\mathcal{V}(\omega)u \in L^p$ for some (sufficiently large) $p \in [1, \frac{4}{3})$ by assumption (A2) and Proposition 19. So Proposition 12 implies for some $\tau_1 > 0$

$$(1 + |\cdot|^\tau_1 - \frac{2}{\tau_1} = (1 + |\cdot|^\tau_1 - \frac{2}{\tau_1}) \mathcal{K}(\omega \pm i0)u = - (1 + |\cdot|^\tau_1 - \frac{2}{\tau_1}) R_0(\lambda \pm \text{sign}(\omega) i0)|\mathcal{V}(\omega)|u \in L^2.$$  

Given that $u$ solves the homogeneous Helmholtz system [22] we deduce from Theorem 13 $u = 0$. \hfill \Box

From this fact we deduce our injectivity estimates. We take the condition $\text{Im}(\zeta^2) \neq 0$ or $\zeta = \omega \pm i0, \omega \in \mathbb{R} \backslash \{0\}$ from the previous proposition into account by restricting our attention to spectral parameters $\zeta$ with nontrivial real parts. Recall from Theorem 10 and Proposition 5 that this implies continuity properties of $\zeta \mapsto \mathcal{K}(\zeta)$.
Proposition 21. Assume (A2),(A3). Then, for any given compact subset $K \subset \{ \zeta \in \mathbb{C} : \Re(\zeta) \neq 0 \}$ we have for all $\zeta \in K \setminus \mathbb{R}$ and all $u = (u_1, u_2) \in L^q(\mathbb{R}^3; \mathbb{C}^6) \cap L^q(\mathbb{R}^3; \mathbb{C}^6)$

$$
\|u\|_{q_1} + \|u\|_{q_2} \lesssim \|(I - K(\zeta))u\|_{q_1} + \|(I - K(\zeta))u\|_{q_2} + |\Im((u, V(\zeta)u))|^{1/2}.
$$

Proof. We argue by contradiction and assume that there are sequences $(\zeta^j) \subset K$ and $(u^j) \subset L^{q_1} \cap L^{q_2}$ such that $\|u^j\|_{q_1} + \|u^j\|_{q_2} = 1$ and

$$
\|(I - K(\zeta^j))u^j\|_{q_1} + \|(I - K(\zeta^j))u^j\|_{q_2} \to 0, \quad \Im((u^j, V(\zeta^j)u^j)) \to 0. \tag{41}
$$

We choose subsequences such that $\zeta^j \to \zeta^* \in K$ and $u^j \to u^*$ in $L^{q_1}$ and $L^{q_2}$. In the case $\zeta^* \in \mathbb{R} \setminus \{0\}$, $\Im(\zeta^*) \to 0^+$ we will write $K(\zeta^*)$ instead of $K(\zeta^* + i0)$ for notational simplicity. Clearly similar arguments apply in the case $\Im(\zeta^*) \to 0^-$. The second part of Corollary 9 and (35) imply $K(\zeta^*)u^j \to K(\zeta^*)u^*$ so that $\|(I - K(\zeta^*))u^j\|_{q_1} + \|(I - K(\zeta^*))u^j\|_{q_2} \to 0$ gives $(I - K(\zeta^*))u^* = 0$ and thus $u^j \to u^*$ in $L^{q_1}$ and in $L^{q_2}$. From the second part of (41) we want to deduce that the injectivity condition (30) holds for $(u^*, \zeta^*)$. So we need to show

$$
\Im((u^*, V(\zeta^*)u^*)) = \lim_{j \to \infty} \Im((u^j, V(\zeta^j)u^j)) = 0.
$$

To verify the first equality we use formula

$$
\Im(\int_{\mathbb{R}^3} \overline{\xi} \cdot V(\zeta)u \, dx) = \Im(\int_{\mathbb{R}^3} \overline{\xi} \cdot V_1(\zeta)u + \overline{\xi} \cdot V_2(\zeta)u + i \zeta (\overline{\xi} \cdot (v \cdot u_m) - \overline{\xi} \cdot v) \, dx) = -\Im(\zeta^2) \int_{\mathbb{R}^3} (\xi \cdot \mu_{\infty} - \xi \cdot \mu) |u|^2 \, dx \quad (42)
$$

$$
= -\Im(\zeta^2) \int_{\mathbb{R}^3} (\xi \cdot \mu_{\infty}) |u|^2 \, dx - \Im \left( i \zeta \int_{\mathbb{R}^3} v \cdot (u_m \times \overline{\xi}) - v \cdot (u \times \overline{\xi}) \, dx \right)
$$

$$
= \Im(\zeta^2) \int_{\mathbb{R}^3} (\xi \cdot \mu_{\infty}) |u|^2 \, dx - 2 \Re(\zeta) \int_{\mathbb{R}^3} v \cdot Re(u_m \times \overline{\xi}) \, dx.
$$

We write $|\xi \cdot \mu_{\infty} - \xi \cdot \mu| = m_1 + m_2$ where $m_1 \in L^{q_1}(\mathbb{R}^3)$, $m_2 \in L^{q_2}(\mathbb{R}^3)$. This is possible due to assumption (A3).

$$
\left| \Im((\zeta^*)^2) \int_{\mathbb{R}^3} (\xi \cdot \mu_{\infty}) |u^*|^2 \, dx - \Im((\zeta^*)^2) \int_{\mathbb{R}^3} (\xi \cdot \mu_{\infty}) |u|^2 \, dx \right|
$$

$$
\leq |(\zeta^*)^2 - (\zeta^*_{\infty})^2| \int_{\mathbb{R}^3} (m_1 + m_2) |u|^2 \, dx + |(\zeta^*)^2| \int_{\mathbb{R}^3} (m_1 + m_2) |u|^2 - |u^*|^2 \, dx
$$

$$
\lesssim |(\zeta^*)^2 - (\zeta^*_{\infty})^2| \left( \|m_1\|_{q_1} \|u\|_{q_1}^2 + \|m_2\|_{q_2} \|u\|_{q_2}^2 \right)
$$

$$
+ \|m_1\|_{q_1} \|u - u^*\|_{q_1} \|u\|_{q_1} + \|m_2\|_{q_2} \|u - u^*\|_{q_2} \|u\|_{q_2}
$$

$$
\lesssim (\|m_1\|_{q_1} + \|m_2\|_{q_2})(|(\zeta^*)^2 - (\zeta^*_{\infty})^2| + \|u_j - u^j\|_{q_1} + |u_j - u^j|_{q_2})
$$

$$
= o(1) \quad (j \to \infty).
$$

Analogous computations yield

$$
\Re(\zeta^*) \int_{\mathbb{R}^3} v \cdot Re(u_m \times \overline{\xi}) \, dx \to \Re(\zeta^*) \int_{\mathbb{R}^3} v \cdot Re(u^*_m \times \overline{\xi}) \, dx \quad (j \to \infty).
$$

So (30) holds and Proposition 20 implies $u^* = 0$. This however contradicts $u^j \to u^* = 0$ and $\|u^j\|_{q_1} + \|u^j\|_{q_2} = 1$. So the assumption was false, which proves the claim. $\square$
4.2. Bounds for $E_\zeta, H_\zeta$. Proposition 21 makes it possible to bound the $L^q$-norm of solutions $u_\zeta := (u_\zeta^p, u_\zeta^q)$ := $(\tilde{E}_\zeta, \tilde{H}_\zeta)$ of the Helmholtz system (30) with $\zeta \in \mathbb{C} \setminus \mathbb{R}$ in terms of $J$ as soon as we find suitable bounds for $\text{Im}(\langle u_\zeta, \mathcal{V}(\zeta) u_\zeta \rangle)$. Those are provided in the next proposition.

Proposition 22. Let the assumptions (A1), (A2), (A3) hold. Then, for any given $\zeta \in \mathbb{C} \setminus \mathbb{R}$ the solutions $u_\zeta := (u_\zeta^p, u_\zeta^q) := (\tilde{E}_\zeta, \tilde{H}_\zeta) := (\varepsilon_3 \tilde{E}_\zeta, \mu_3 \tilde{H}_\zeta) \in L^q(\mathbb{R}^3; \mathbb{C}^6)$ of the Helmholtz system (30) satisfy

$$
\int_{\mathbb{R}^3} \nu \cdot \text{Re}(u_\zeta^p \times \overline{u_\zeta^p}) \, dx = \text{Im}(\zeta) \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) |u_\zeta|^2 \, dx
$$

$$
+ \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \text{Re} \left( \mu^{-1} J_m^\zeta \cdot u_\zeta^m - \varepsilon^{-1} J_\zeta^c \cdot u_\zeta^c \right) \, dx.
$$

In particular, for $\zeta \in \mathbb{R}$ and any compact set $K \subset \mathbb{C},$

$$
|\text{Im}(\langle u_\zeta, \mathcal{V}(\zeta) u_\zeta \rangle)| \leq |\text{Im}(\zeta)| (\|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2})^2 + (\|J_\zeta^c\|_p + \|J_m^\zeta\|_p) (\|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2}).
$$

Proof. We recall from (29) the identity

$$
v = 2\nabla((\varepsilon \mu)^{1/2}) = (\varepsilon \mu)^{-1/2} \nabla (\varepsilon \mu) = (\varepsilon \mu)^{-1/2} \nabla (\varepsilon \mu - \varepsilon \infty \mu_\infty).
$$

Then integration by parts gives

$$
\int_{\mathbb{R}^3} \nu \cdot \text{Re}(u_\zeta^p \times \overline{u_\zeta^p}) \, dx
$$

$$
= \int_{\mathbb{R}^3} \nabla (\varepsilon \mu - \varepsilon \infty \mu_\infty) \cdot \text{Re} \left( H_\zeta \times \overline{E_\zeta} \right) \, dx
$$

$$
= - \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \left[ \nabla \cdot \text{Re} \left( H_\zeta \times \overline{E_\zeta} \right) \right] \, dx
$$

$$
= - \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \left\{ \left( \nabla \times H_\zeta \right) \cdot \overline{E_\zeta} - \left( \nabla \times \overline{E_\zeta} \right) \cdot H_\zeta \right\} \, dx
$$

$$
= - \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \text{Re} \left( i\zeta \varepsilon E_\zeta + J_\zeta^c \right) \cdot \overline{E_\zeta} - \left( -i\zeta \mu H_\zeta + J_m^\zeta \right) \cdot H_\zeta \, dx
$$

$$
= - \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \text{Re} \left( i\zeta \varepsilon E_\zeta^2 + J_\zeta^c \cdot \overline{E_\zeta} - i\zeta \mu |H_\zeta|^2 - J_m^\zeta \cdot H_\zeta \right) \, dx
$$

$$
= \text{Im}(\zeta) \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) (\varepsilon |E_\zeta|^2 + \mu |H_\zeta|^2) \, dx + \int_{\mathbb{R}^3} (\varepsilon \mu - \varepsilon \infty \mu_\infty) \text{Re} \left( J_m^\zeta \cdot H_\zeta - J_\zeta^c \cdot \overline{E_\zeta} \right) \, dx
$$

So Hölder’s inequality and (A3) imply with $m_1, m_2$ as in the proof of Proposition 21

$$
\left| 2 \text{Re}(\zeta) \int_{\mathbb{R}^3} \nu \cdot \text{Re}(u_\zeta^p \times \overline{u_\zeta^p}) \, dx \right| \leq \text{Im}(\zeta) ((\|m_1\|_{q_1} \|u_\zeta\|_{q_1}^2 + \|m_2\|_{q_2} \|u_\zeta\|_{q_2}^2)
$$

$$
+ \int_{\mathbb{R}^3} (m_1 + m_2)(\|J_m^\zeta\|_{q_1} + \|J_\zeta^c\|_{q_2}) \, dx.
$$

We have $m_1 \in L^{q_1}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$ and $m_2 \in L^{q_2}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$ by (A1), $J_m^\zeta, J_\zeta^c \in L^p \cap L^\infty$ and $u_m^p, u_\zeta^c \in L^q \cap L^\infty$. Our assumptions on $p, \tilde{p}, q_1, q_2$ from the theorem imply

$$
\frac{1}{\infty} + \frac{1}{p} + \frac{1}{q_1} \leq 1 \leq \frac{q_1 - 2}{q_1} + \frac{1}{p} + \frac{1}{q_1},
$$

$$
\frac{1}{\infty} + \frac{1}{p} + \frac{1}{q_2} \leq 1 \leq \frac{q_2 - 2}{q_2} + \frac{1}{p} + \frac{1}{q_2}.
$$
So we can find suitable exponents for Hölder’s inequality and thus obtain
\[ 2 \text{Re}(\zeta) \int_{\mathbb{R}^3} v \cdot \text{Re}(u_\zeta^* \times \overline{u_\zeta}) \, dx \lesssim |\text{Im}(\zeta)||v||u_\zeta||u_\zeta^*||u_\zeta^*|^2 \]
\[ + \langle |\mathcal{J}_\zeta^*|_p + |\mathcal{J}_m^*|_p + |\mathcal{J}_m^*|_p \rangle |\mathcal{J}_\zeta^*||u_\zeta||u_\zeta^*||u_\zeta^*|_p + |\mathcal{J}_m^*|_p \rangle. \]
Moreover, \( \text{Im}(\zeta^2) = 2 \text{Re}(\zeta) \text{Im}(\zeta) \) gives
\[ |\text{Im}(\zeta^2)| \lesssim |\text{Im}(\zeta)||v||u_\zeta||u_\zeta^*||u_\zeta^*|^2 \]
so that 143 is proved in view of 142.

Combining this fact and the injectivity estimates from Proposition 21 we obtain uniform bounds for the solutions \((E_\zeta, H_\zeta)\) provided that \(|\text{Im}(\zeta)|\) is sufficiently small.

**Corollary 23.** Let the assumptions (A1),(A2),(A3) hold and let \( K \subset \mathbb{C} \) be compact. Then, for \(|\text{Im}(\zeta)|\) sufficiently small, any solution \((E_\zeta, H_\zeta)\) of the time-harmonic Maxwell system 14 for \( \zeta \in K \cap \mathbb{R} \) satisfies
\[ \|E_\zeta\|_q + \|H_\zeta\|_q \lesssim \langle R\zeta^2 |\zeta\epsilon_{\infty}\mu_{\infty} \rangle \|L_1(\zeta^2) + L_2(\zeta^2)\|_{q_1} \]
\[ + \langle R\zeta^2 |\zeta\epsilon_{\infty}\mu_{\infty} \rangle \|L_1(\zeta^2) + L_2(\zeta^2)\|_{q_2} + \|L_3(\zeta^2)\|_p + \|L_3(\zeta^2)\|_p. \]

**Proof.** We define \( u_\zeta := \langle E_\zeta, H_\zeta \rangle := (\epsilon_\zeta H_\zeta, \mu_\zeta H_\zeta) \). By Lemma 16 these functions solve the Helmholtz system 30 and hence satisfy the representation formula 37. So Proposition 23 and Proposition 22 give
\[ \|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2} \lesssim \|I - K(\zeta)\|_{q_1} ||u_\zeta||_{q_1} + \text{Im}(u_\zeta, V(\zeta)u_\zeta)|^{1/2} \]
\[ + \sqrt{\text{Im}(\zeta)}(\|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2}) + \|J_3(\zeta)\|_p + \|J_3(\zeta)\|_p. \]
This and \( \|u_\zeta\|_q \lesssim \|u_\zeta\|_{q_1} + \|u_\zeta\|_{q_2} \) yields the corresponding bound for \( u_\zeta \) provided that \(|\text{Im}(\zeta)|\) is sufficiently small. Assumption (A1) implies \( \|E_\zeta\|_r + \|H_\zeta\|_r \lesssim \|u_\zeta\|_r \) for \( r \in \{q_1, q_2\} \) and (44) follows.

**4.3. Proof of the Limiting Absorption Principle.** We first prove the existence of the functions \((E_\zeta, H_\zeta)\) for which we provided above. We recall that it is defined as the unique solution in \( H^1(\mathbb{R}^3; \mathbb{C}^3) \subseteq L^2(\mathbb{R}^3; \mathbb{C}^3) \cap L^p(\mathbb{R}^3; \mathbb{C}^3) \) of the time-harmonic Maxwell system 1 with divergence-free currents \( J_\zeta^*, J_m^* \) satisfying \( (J_\zeta^*, J_m^*) \to (J_\zeta, J_m) \) in \( L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3) \) as \( \zeta \to \omega \in \mathbb{R} \setminus \{0\} \).

**Proposition 24.** Let \( p, \tilde{p} \in (1, \infty) \) and assume \( J_\zeta, J_m \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3) \) to be divergence-free. Then there are divergence-free vector fields \( J_\zeta^*, J_m^* \in L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3) \) satisfying \( (J_\zeta^*, J_m^*) \to (J_\zeta, J_m) \) in \( L^p(\mathbb{R}^3; \mathbb{C}^3) \cap L^2(\mathbb{R}^3; \mathbb{C}^3) \) as \( \zeta \to \omega \in \mathbb{R} \setminus \{0\} \).

**Proof.** The mapping \( f \mapsto f - F^{-1}(\langle |\zeta|^{-2} \xi \xi^T \tilde{f} \rangle) \) is a bounded linear operator from \( L^p \cap L^\tilde{p} \) to the divergence-free vector fields in \( L^p \cap L^\tilde{p} \). This is a consequence of the \( L^p \cap L^\tilde{p} \)-boundedness of Riesz transforms. So for any given \( f \in L^p \cap L^\tilde{p} \) we can choose \( (f_m) \subset \mathcal{S} \) such that \( f_m \) converges to \( f \) in \( L^p \cap L^\tilde{p} \). The sequence \( (\Omega f_m) \) then has the desired properties.

Next we show that for \( J_\zeta^*, J_m^* \) as in Proposition 23 there are uniquely determined solutions \((E_\zeta, H_\zeta)\) in \( H^1(\mathbb{R}^3; \mathbb{C}^3) \). In the proof we will need the following result for \( r = 2 \).

**Proposition 25.** Assume (A1) and \( \zeta \in \mathbb{C}, r \in (1, \infty) \). Then every solution of \( 41 \) satisfies
\[ \|\nabla E\|_r + \|\nabla H\|_r \lesssim (1 + |\zeta|)(\|E\|_r + \|H\|_r) + \|J_\zeta\|_r + \|J_m\|_r \]

20 LUCREZIA COSSETTI, RAINER MANDEL
Proof. Since $D = \varepsilon E$ and $B = \mu H$ are divergence-free, we have
\[
\nabla \cdot E = \varepsilon^{-1} \nabla \varepsilon \cdot E, \quad \nabla \cdot H = \mu^{-1} \nabla \mu \cdot H.
\]
This and [51] Theorem 1.1] imply
\[
\|\nabla E\|_r + \|\nabla H\|_r \lesssim \|\nabla \times E\|_r + \|\nabla \cdot E\|_r + \|\nabla \times H\|_r + \|\nabla \cdot H\|_r
\]
\[
\lesssim |i\varepsilon \mu H + J_m|_r + \|\varepsilon^{-1} \nabla \varepsilon \cdot E\|_r + \|i\varepsilon \mu H + J_m|_r + \|\mu^{-1} \nabla \mu \cdot H\|_r
\]
\[
\lesssim (1 + |\varepsilon|)(\|E\|_r + |H|_r) + \|J_m\|_r + \|J_m\|_r.
\]
□

Proposition 26. Assume (A1). Then, for $\zeta \in \mathbb{C}$ with $\text{Re}(\zeta), \text{Im}(\zeta) \neq 0$, there is a unique solution $(E_\zeta, H_\zeta) \in H^1(\mathbb{R}^3; \mathbb{C}^6)$ of (1) for the divergence-free currents given by $J_\zeta, J_\zeta' \in L^2(\mathbb{R}^3; \mathbb{C}^3)$.

Proof. The existence and uniqueness of such a solution $(E_\zeta, H_\zeta) \in H(\text{curl}; \mathbb{R}^3) \times H(\text{curl}; \mathbb{R}^3)$ can be proved as in [10] Section 7.4. From $\varepsilon, \mu \in W^{1,\infty}(\mathbb{R}^3)$ by (A1) and Proposition 25 for $r = 2$ we obtain $(E_\zeta, H_\zeta) \in H^1(\mathbb{R}^3; \mathbb{C}^6)$.

The preceding propositions ensure that the sequences of solutions $(E_\zeta, H_\zeta)$ we were speaking of really exist in the space $H^1(\mathbb{R}^3; \mathbb{C}^6)$ and in particular in $L^q(\mathbb{R}^3; \mathbb{C}^6)$ for all $q \in (3, 6)$ by Sobolev’s Embedding Theorem. In Corollary 25 we showed that $(E_\zeta, H_\zeta)$ remain bounded once we have bounds for suitable Lebesgue-norms of $\tilde{J}_\zeta$ and $R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta + L_2 \tilde{J}_\zeta]$ which are independent of $\text{Im}(\zeta)$. As mentioned earlier, this can be achieved rather easily with the aid of Theorem 6 and a suitable modification of it when first order derivatives are involved, see Theorem 23 in the Appendix.

Proposition 27. Assume (A1) and let $K \subset \{\zeta \in \mathbb{C} : \text{Re}(\zeta) \neq 0\}$ be compact. Then, for $\zeta \in K \setminus \mathbb{R}$ and $\tilde{J}_\zeta := (\varepsilon J_\zeta, \mu J_\zeta')$ as above, we have
\[
\|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta + L_2 \tilde{J}_\zeta]\|_{q_1} + \|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta + L_2 \tilde{J}_\zeta]\|_{q_2} \lesssim \|\tilde{J}_\zeta\|_p + \|\tilde{J}_\zeta\|_\tilde{p}.
\]
Proof. To bound the term involving $L_1$ we use Theorem 6. Since $\|L_1(\zeta)\|_q \lesssim 1 + |\zeta| \lesssim 1$ by the definition of $L_1$ from (29) and assumption (A1) we get
\[
\|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta]\|_{q_1} \lesssim \|L_1(\zeta)\tilde{J}_\zeta\|_p \lesssim \|\tilde{J}_\zeta\|_p \lesssim \|\tilde{J}_\zeta\|_\tilde{p}.
\]
The estimate for the term involving $L_2$ corresponds to the special case $n = 3, m = 6$ in Theorem 30
\[
\|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_2 \tilde{J}_\zeta]\|_{q_1} \lesssim \|\tilde{J}_\zeta\|_p + \|\tilde{J}_\zeta\|_\tilde{p} \lesssim \|\tilde{J}_\zeta\|_p + \|\tilde{J}_\zeta\|_\tilde{p}.
\]
Since the same holds for $q_1$ replaced by $q_2$, this proves the claim. □

Now we are in the position to prove the Limiting Absorption Principle for time-harmonic Maxwell’s equations (1).

Proof of Theorem 1. In order to prove Theorem 1 it suffices to combine the auxiliary results that we established above. So assume (A1),(A2),(A3) and let $p, q$, and $J_m, J_m' \in L^p \cap L^p$ be given as in the theorem. We prove the existence of the solutions $(E_\zeta, H_\zeta)$ with the desired properties by proving the convergence of the solutions $(E_\zeta, H_\zeta)$ as outlined in part (i) of the theorem. To reduce the notation we only consider the limit $\zeta \to \omega + i0$.

Proof of (i): For $\zeta \in \mathbb{C} \setminus \mathbb{R}$ with $\text{Im}(\zeta) > 0, \text{Re}(\zeta) \neq 0 \leq 0$ let $J_\zeta, J_\zeta' \in L^p \cap L^p \cap L^2$ be the divergence-free approximating sequence whose existence is ensured by Proposition 21. Let then $(E_\zeta, H_\zeta)$ denote the unique $H^1$-solutions of the corresponding inhomogeneous time-harmonic Maxwell system (1) from Proposition 26 Corollary 24 yields for small $|\text{Im}(\zeta)|$
\[
\|E_\zeta\|_q + \|H_\zeta\|_q \lesssim \|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta + L_2 \tilde{J}_\zeta]\|_{q_1} + \|R_0(\zeta^2 \varepsilon \mu_{\infty})[L_1(\zeta)\tilde{J}_\zeta + L_2 \tilde{J}_\zeta]\|_{q_2} + \|\tilde{J}_\zeta\|_p + \|\tilde{J}_\zeta\|_\tilde{p}
\]
where $\tilde{J}_\zeta := (\mu J_\zeta, \varepsilon J_\zeta')$. So Proposition 24 implies
\[
\|E_\zeta\|_q + \|H_\zeta\|_q \lesssim \|\tilde{J}_\zeta\|_p + \|\tilde{J}_\zeta\|_\tilde{p} = |J|_p + |J|_\tilde{p} + \mathcal{O}(1) \quad \text{as } \zeta \to \omega + i0,
\]
which proves that the sequence of approximate solutions \((E_\zeta, H_\zeta)\) is bounded in \(L^q\). So a subsequence of \((u_\zeta)\) defined via \(u_\zeta := (\tilde{E}_\zeta, H_\zeta) := (e^{\frac{\imath}{\varepsilon}}E_\zeta, \mu^{\frac{\imath}{\varepsilon}}H_\zeta)\) converges weakly to some \(u_\zeta^w := (\tilde{E}_\zeta^w, H_\zeta^w)\) in \(L^q\). Defining \((E_\zeta^+, H_\zeta^+) := (e^{\frac{\imath}{\varepsilon}}E_\zeta^+, \mu^{\frac{\imath}{\varepsilon}}H_\zeta^+)\) we thus obtain a weak solution of the time-harmonic Maxwell system \(\mathbf{E}\) (for \(\zeta = \omega\)) that satisfies

\[
\|E_\zeta^w\|_q + \|H_\zeta^w\|_q \lesssim \|\tilde{E}_\zeta^w\|_q + \|\tilde{H}_\zeta^w\|_q \lesssim \|J\|_p + \|J\|_p.
\]

In the first estimate assumption (A1) is used. This proves the existence of the solution \((E_\zeta^+, H_\zeta^+)\) along with the corresponding norm estimate. To conclude the proof of (i) we need to show that for any given approximations \(J_\zeta, J_\zeta^e\) as above the full sequence \((u_\zeta)\) converges to \(u_\zeta^w\).

So let \((\zeta_j), (\tilde{\zeta}_j)\) sequences converging to \(\omega + i0\) and let \(J^{1,\zeta_j}, J^{2,\tilde{\zeta}_j}\) be divergence-free currents converging to \(J\). Let \(u_\zeta^1, u_\zeta^2 \in L^q\) denote the corresponding weak limits, i.e., \(u_{\zeta_j} \rightharpoonup u_\zeta^1, u_{\tilde{\zeta}_j} \rightharpoonup u_\zeta^2\). We need to show \(u_\zeta^1 = u_\zeta^2\). From \(\mathbf{37}\) we infer \((I - \mathcal{K}(\zeta_j))u_{\zeta_j} = f_\zeta^1\) and \((I - \mathcal{K}(\tilde{\zeta}_j))u_{\zeta_j} = f_\zeta^2\) where

\[
\begin{align*}
    f_\zeta^1 &= R_0(\zeta_j^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\zeta_j)\tilde{J}^{1,\zeta_j} + \mathcal{L}_2\tilde{J}^{1,\zeta_j}\right], \\
    f_\zeta^2 &= R_0(\zeta_j^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\zeta_j)\tilde{J}^{2,\zeta_j} + \mathcal{L}_2\tilde{J}^{2,\zeta_j}\right], \\
    f_\zeta^+ &= R_0((\omega + i0)^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\omega)\tilde{J} + \mathcal{L}_2\tilde{J}\right].
\end{align*}
\]

Using first Proposition \(\mathbf{27}\) and \(\tilde{J}^{1,\zeta_j} \to \tilde{J}\), then the uniform boundedness of the resolvents \(R_0(\zeta_j)\) and \(\mathcal{L}_1(\zeta_j) \to \mathcal{L}_1(\omega)\) in \(L^\infty\), and finally the pointwise convergence \(R_0(\zeta_j^2\varepsilon_\infty\mu_\infty) \to R_0((\omega + i0)^2\varepsilon_\infty\mu_\infty)\) we infer

\[
\begin{align*}
    f_\zeta^1 &= R_0(\zeta_j^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\zeta_j)\tilde{J}^{1,\zeta_j} + \mathcal{L}_2\tilde{J}^{1,\zeta_j}\right] \\
    &= R_0(\zeta_j^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\zeta_j)\tilde{J} + \mathcal{L}_2\tilde{J}\right] + o(1) \\
    &= R_0(\zeta_j^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\omega)\tilde{J} + \mathcal{L}_2\tilde{J}\right] + o(1) \\
    &= R_0((\omega + i0)^2\varepsilon_\infty\mu_\infty)\left[\mathcal{L}_1(\omega)\tilde{J} + \mathcal{L}_2\tilde{J}\right] + o(1) \\
    &= f_\zeta^+ + o(1).
\end{align*}
\]

Since the same argument applies to \(f_\zeta^2\), we get \(f_\zeta^1 - f_\zeta^2 \to f_\zeta^+ - f_\zeta^+ = 0\). Using the continuity and compactness properties of \(\mathcal{K}\) from Corollary \(\mathbf{9}\) we infer that \(w := u_\zeta^1 - u_\zeta^2\) satisfies

\[
\begin{align*}
    w &= u_{\zeta_j} - u_{\tilde{\zeta}_j} + o_w(1) \\
    &= \mathcal{K}(\zeta_j)u_{\zeta_j} - \mathcal{K}(\tilde{\zeta}_j)u_{\tilde{\zeta}_j} + f_\zeta^1 - f_\zeta^2 + o_w(1) \\
    &= \mathcal{K}(\omega + i0)u_{\zeta_j} - \mathcal{K}(\omega + i0)u_{\tilde{\zeta}_j} + o_w(1) \\
    &= \mathcal{K}(\omega + i0)w + o_w(1).
\end{align*}
\]

Here, \(o_w(1)\) stands for a null sequence in the weak topology in \(L^q\). The function \((\tilde{w}_e, \tilde{w}_m) := w\) is a weak solution of the homogeneous time-harmonic Maxwell system \(\mathbf{4}\) for \(\zeta = \omega\) and \(\tilde{J} = 0\). Restarting the computations in Proposition \(\mathbf{22}\) in the limiting case \(\text{Im}(\zeta) = 0\) one finds

\[
2\pi \int_{\mathbb{R}^3} v \cdot \text{Re}(\hat{w}_m \times \hat{w}_e) \, dx = 0.
\]

So Proposition \(\mathbf{20}\) gives \(w = 0\). This proves that all possible weak limits coincide. Hence, the standard subsequence-of-subsequence argument ensures that all approximating sequences weakly converge to the same limit as \(\zeta \to \omega + i0\).

To finish the proof of (i) it remains to show that this convergence also holds in the strong sense and hence, by elliptic regularity theory, in \(H^1_{\text{loc}}(\mathbb{R}^3; \mathbb{C}^6)\). To this end we recall from above \((I - \mathcal{K}(\zeta_j))u_{\zeta_j} = f_{\zeta_j}\). From the definition of \(\mathcal{K}\) and the second part of Proposition \(\mathbf{8}\) we get \(\mathcal{K}(\zeta_j)u_{\zeta_j} \to \mathcal{K}(\omega + i0)u_{\zeta_j}^+\) in \(L^q\). Moreover, we showed above \(f_{\zeta_j} \to f_\zeta^+\) in \(L^q\) as \(j \to \infty\). Hence, we conclude that \((u_{\zeta_j})\) converges in \(L^q\). Since the limit
necessarily coincides with the weak limit, we finally obtain \( u_{\zeta_i} \to u_{\omega}^+ \) as \( \zeta_j \to \omega + i0 \). This proves (i) as well as
\[
(I - \mathcal{K}(\omega \pm i0))u_{\omega}^+ = R_0 \left( (\omega \pm i0)^2 \varepsilon_{\infty} \mu_{\infty} \right) \left[ L_1(\omega)\tilde{J} + L_2\tilde{J} \right].
\] (45)
In particular, \( u_{\omega}^+ \) solves the Helmholtz system mentioned in the theorem.

We finally prove part (iii) of the theorem, so we assume that the divergence-free currents \((J_\epsilon, J_m)\) lie in the smaller space \( L^p \cap L^2 \subseteq L^p \cap L^\delta \) (because \( p < \hat{p} < q \)). From above we get a solution \((E, H) \in L^q\) which, according to Proposition \( \text{[\ref{prop:weak}} \) satisfies
\[
\|\nabla E\|_q + \|\nabla H\|_q \lesssim (1 + |\xi|)(\|E\|_q + \|H\|_q) + \|J_\epsilon\|_q + \|J_m\|_q \lesssim \|J\|_p + \|J\|_q.
\]
Hence we conclude \( E, H \in W^{1,q}(\mathbb{R}^3; \mathbb{C}^3) \) as claimed.

\[ \square \]

**Appendix A: Proof of Lemma [\ref{lem:main}]**

This appendix is devoted to the proof of Lemma \( \text{[\ref{lem:main}} \) and, in particular, to showing the validity of \( \text{[\ref{eq:main}} \). For notational simplicity we verify \( \text{[\ref{eq:main}} \) in the pointwise sense assuming that classical derivatives exist. This carries over to weak solutions by moving first order derivatives to the test functions. So let \((E, H)\) denote a weak solution of \( \text{[\ref{eq:main}} \) as assumed. Then \( \tilde{(E, H)} = (\varepsilon^{-\frac{1}{2}} D, \mu^{-\frac{1}{2}} B) \) where \( D, B \) are divergence-free vector fields. The latter follows from the fact that \( J_\epsilon, J_m \) are divergence-free. So we have \( \nabla \times \nabla \times D = \nabla (\nabla \cdot D) - \Delta D = -\Delta D \) and obtain
\[
\Delta \tilde{E} = \Delta (\varepsilon^{-\frac{1}{2}}) D + 2|\nabla (\varepsilon^{-\frac{1}{2}}) \cdot \nabla| D + \varepsilon^{-\frac{1}{2}} \Delta D
\]
\[
= \left( \frac{3}{4} \varepsilon^{-1} |\nabla \varepsilon|^2 - \frac{1}{2} \varepsilon^{-1} \Delta \varepsilon \right) \tilde{E} - \varepsilon^{-\frac{1}{2}} |\nabla \varepsilon| D - \varepsilon^{-\frac{1}{2}} \nabla \times \nabla \times D.
\] (46)

The second order term can be simplified with the aid of \( \text{[\ref{eq:main}} \). The vector calculus identities
\[
\nabla \times (\psi A) = \nabla \psi \times A + \psi(\nabla \times A),
\]
\[
\nabla \times (A \times C) = A(\nabla \cdot C) - C(\nabla \cdot A) + (C \cdot \nabla) A - (A \cdot \nabla) C
\]
for scalar fields \( \psi \) and vector fields \( A, C \) lead to
\[
\nabla \times \nabla \times D = \nabla \times \nabla \times (\varepsilon E)
\]
\[
= \nabla \times (\nabla (\varepsilon \cdot E + \varepsilon (\nabla \times E))
\]
\[
= \nabla \times (\nabla \varepsilon \cdot E + \varepsilon \cdot \nabla \times E - \varepsilon \cdot \mu H + J_m)]
\]
\[
= \nabla \times (\nabla \varepsilon \cdot E) - i\varepsilon \nabla (\varepsilon \mu) \times H - i\varepsilon \nabla (\varepsilon \times H) + \nabla \times (\varepsilon J_m)
\]
\[
= \nabla \varepsilon (\nabla \cdot E) - (\Delta \varepsilon) E + (E \cdot \nabla) \nabla \varepsilon - (\varepsilon \cdot \nabla) E
\]
\[
- i\varepsilon \nabla (\varepsilon \mu) \times H - i\varepsilon \nabla (\varepsilon \mu) (i\varepsilon E + J_\epsilon) + \nabla \times (\varepsilon \cdot J_m).
\]
To simplify these terms we use that \( D = \varepsilon \tilde{E} \) is divergence-free and thus \( \nabla \times E = -\varepsilon^{-1} \nabla \varepsilon \cdot E \). Moreover,
\[
(\nabla \varepsilon \cdot \nabla) E = (\nabla \varepsilon \cdot \nabla)(\varepsilon^{-1} D) = -\varepsilon^{-2} |\nabla \varepsilon|^2 D + \varepsilon^{-1}(\nabla \varepsilon \cdot \nabla) D.
\]
This implies
\[
-\varepsilon^{-\frac{1}{2}} \nabla \times \nabla \times D = -\varepsilon^{-\frac{1}{2}} \cdot \left[ -\varepsilon^{-1} \nabla \varepsilon (\nabla \cdot E) - (\Delta \varepsilon) E + (E \cdot \nabla) \nabla \varepsilon + \varepsilon^{-2} |\nabla \varepsilon|^2 D - \varepsilon^{-1} (\nabla \varepsilon \cdot \nabla) D \right]
\]
\[
+ i\varepsilon (\varepsilon \mu) \frac{1}{2} \nabla (\varepsilon \mu) \times H - \varepsilon \frac{2}{2} (\varepsilon \mu) \tilde{J}_\epsilon - \varepsilon^{-\frac{1}{2}} \nabla \times (\varepsilon \cdot J_m)
\]
\[
= \varepsilon^{-2} \nabla \varepsilon (\nabla \varepsilon) \tilde{E} + \varepsilon^{-1} (\varepsilon \cdot \nabla) \tilde{E} - \varepsilon^{-1} (\tilde{E} \cdot \nabla) \nabla \varepsilon - \varepsilon^{-2} |\nabla \varepsilon|^2 \tilde{E} + \varepsilon^{-\frac{1}{2}} (\varepsilon \cdot \nabla) D
\]
\[
+ i\varepsilon (\varepsilon \mu) \frac{1}{2} \nabla (\varepsilon \mu) \times H - \varepsilon \frac{2}{2} (\varepsilon \mu) \tilde{J}_\epsilon - \nabla \times \tilde{J}_m - \frac{1}{2} \varepsilon^{-1} \nabla \varepsilon \times \tilde{J}_m.
\]
Combining this formula with \( \text{[\ref{lem:main}} \) we find that the first order terms (involving \( D \)) cancel and
\[
\Delta \tilde{E} = \left( \frac{3}{4} \varepsilon^{-2} |\nabla \varepsilon|^2 - \frac{1}{2} \varepsilon^{-1} \Delta \varepsilon \right) \tilde{E} + \varepsilon^{-2} \nabla \varepsilon (\nabla \varepsilon) \tilde{E} + \varepsilon^{-1} \Delta \tilde{E} - \varepsilon^{-1} (\tilde{E} \cdot \nabla) \nabla \varepsilon - \varepsilon^{-2} |\nabla \varepsilon|^2 \tilde{E}
\]
\[ + i\zeta(\varepsilon \mu)^{-\frac{1}{2}} \nabla(\varepsilon \mu) \times \hat{H} - \zeta^2 \varepsilon \mu \hat{E} + i\zeta(\varepsilon \mu)^{\frac{3}{2}} \hat{J}_e - \nabla \times \hat{J}_m - \frac{1}{2} \varepsilon^{-1} \nabla e \times \hat{J}_m \]

\[ = \left( -\frac{1}{4} e^{-2} |\nabla e|^2 + \frac{1}{2} e^{-1} \Delta e + e^{-2} \nabla e (\nabla e)^T - \zeta^2 \varepsilon \mu - \varepsilon^{-1} \nabla \nabla^T e \right) \hat{E} \]

\[ + i\zeta(\varepsilon \mu)^{-\frac{1}{2}} \nabla(\varepsilon \mu) \times \hat{H} + i\zeta(\varepsilon \mu)^{\frac{3}{2}} \hat{J}_e - \nabla \times \hat{J}_m - \frac{1}{2} \varepsilon^{-1} \nabla e \times \hat{J}_m \]

\[ = \left[ \varepsilon^{-\frac{1}{2}} \Delta(\varepsilon^{\frac{1}{2}}) - \nabla \nabla^T (\log e) + \zeta^2 (\varepsilon_{\infty} \mu_{\infty} - \varepsilon \mu) \right] \hat{E} - \zeta^2 \varepsilon_{\infty} \mu_{\infty} \hat{E} \]

\[ + 2i\zeta \nabla ((\varepsilon \mu)^{\frac{1}{2}}) \times \hat{H} + i\zeta(\varepsilon \mu)^{\frac{3}{2}} \hat{J}_e - \nabla \times \hat{J}_m - \frac{1}{2} \nabla (\log e) \times \hat{J}_m. \]

This corresponds to the first line in (90). To derive the second line, one proceeds in an analogous manner and subsequently derives the formulas:

\[ \Delta \hat{H} = \left( \frac{3}{4} \mu^{-2} |\nabla \mu|^2 - \frac{1}{2} \mu^{-1} \Delta \mu \right) \hat{H} - \mu^{-\frac{5}{2}} [\nabla \mu \cdot \nabla] B - \mu^{-\frac{3}{2}} \nabla \times \nabla \times B, \]

\[ \nabla \times \nabla \times B = \nabla \mu(\nabla \cdot H) - (\Delta \mu) H + (H \cdot \nabla) \nabla \mu - (\nabla \mu \cdot \nabla) H \]

\[ + i\zeta(\varepsilon \mu) \times E + i\varepsilon \mu(-i\zeta H + \hat{J}_m) + \nabla \times (\mu^{\frac{3}{2}} \hat{J}_e), \]

\[ - \mu^{-\frac{5}{2}} \nabla \times \nabla \times B = \mu^{-2} \nabla \mu(\nabla \mu) \hat{H} + \mu^{-1} (\Delta \mu) \hat{H} - \mu^{-1} (\hat{H} \cdot \nabla) \nabla \mu - \mu^{-2} |\nabla \mu|^2 \hat{H} + \mu^{-\frac{2}{3}} (\nabla \mu \cdot \nabla) B \]

\[ - i\zeta(\varepsilon \mu)^{-\frac{1}{2}} \nabla \nabla^T (\log \mu) + \zeta^2 (\varepsilon_{\infty} \mu_{\infty} - \varepsilon \mu) \right] \hat{H} - \zeta^2 \varepsilon_{\infty} \mu_{\infty} \hat{H} \]

\[ - 2i\zeta \nabla ((\varepsilon \mu)^{\frac{1}{2}}) \times \hat{E} - i\zeta(\varepsilon \mu)^{\frac{3}{2}} \hat{J}_e - \nabla \times \hat{J}_m - \frac{1}{2} \nabla (\log \mu) \times \hat{J}_e. \]

**Appendix B: Uniform estimates for \( R_0(\zeta) \partial_j \)**

This appendix is devoted to the proof of Theorem 28 (see below) that we needed in the proof of the Limiting Absorption Principle for Maxwell’s equations. In order to do that we need the following classical result on Fourier multipliers.

**Theorem 28** (Mikhlin-Hörmander). Let \( n \in \mathbb{N}, 1 < r < \infty \). For \( k := \left\lfloor \frac{n}{2} \right\rfloor + 1 \) assume that \( m \in C^k(\mathbb{R}^n) \) satisfies \( |\partial_\alpha m(\xi)| \leq A|\xi|^{-|\alpha|} \) for all multi-indices \( \alpha \in \mathbb{N}_0^n \) with \( |\alpha| \leq k \). Then

\[ \| F^{-1}(mFf) \|_r \leq C_{n,r} A \| f \|_r \]

**Proof.** The result is a particular case of Theorem 6.2.7 in [21].

We also need some boundedness properties of Bessel potentials.

**Theorem 29.** Assume \( n \in \mathbb{N}, n \geq 2 \). Let \( J_1 \) be the Bessel potential of order 1 defined as

\[ J_1 f := F^{-1} \left( \frac{1}{\sqrt{1 + |\xi|^2}} f \right), \quad \text{alternatively,} \quad J_1 f := G * f := F^{-1} \left( \frac{1}{\sqrt{1 + |\xi|^2}} \right) * f, \]

Assume \( 1 \leq p \leq q \leq \infty \) be such that

\[ 0 \leq \frac{1}{p} - \frac{1}{q} \leq \frac{1}{n}, \quad \left( \frac{1}{p}, \frac{1}{q} \right) \notin \left\{ \left( 1, \frac{1}{n} \right), \left( \frac{1}{n}, 0 \right) \right\}. \]

Then \( J_1 \) is a bounded operator from \( L^p(\mathbb{R}^n) \) to \( L^q(\mathbb{R}^n) \).
Proof. From [22 Corollary 1.2.6 (a),(b)] and interpolation we have
\[ J_1: L^p(\mathbb{R}^n) \to L^q(\mathbb{R}^n), \quad \text{if } 1 < p \leq q < \infty, \quad \frac{1}{p} - \frac{1}{q} = \frac{1}{n}. \]
Thus, it remains to study the case \( p = 1 \) and the case \( q = \infty \). Let us start with the case \( p = 1 \). Again from [22 Corollary 1.2.6 (b)] we have that \( J_1: L^1(\mathbb{R}^n) \to L^{p,\infty}(\mathbb{R}^n) \), when \( p = 1 \) and for \( \frac{1}{p} - \frac{1}{q} = \frac{1}{n} \). Moreover, from [22 Corollary 1.2.6 (a)], we know that \( J_1: L^1(\mathbb{R}^n) \to L^1(\mathbb{R}^n) \). Thus, Marcinkiewicz’ interpolation theorem gives that \( J_1: L^1(\mathbb{R}^n) \to L^1(\mathbb{R}^n) \), with \( 1 - \frac{1}{q} < \frac{1}{n} \). We continue with the case \( q = \infty \). We know from the proof of [22 Corollary 1.2.6 (b)] that the kernel \( G \) satisfies \( |G(x)| \lesssim |x|^{1-n} \) if \( |x| \leq 2 \) and \( |G(x)| \lesssim e^{-\frac{|x|}{|\xi|}} \) if \( |x| \geq 2 \). Using Young’s convolution inequality we thus get
\[ \|J_1f\|_\infty = \|G * f\|_\infty \lesssim \|G\|_p \|f\|_p, \quad \frac{1}{p} + \frac{1}{p'} = 1. \]
The proof is concluded once one observes that \( \|G\|_p < \infty \) for \( 0 \leq \frac{1}{p} < \frac{1}{n} \). \( \square \)

With these results at hand, we are in the position to prove the following estimates that complement Theorem 30.

**Theorem 30.** Let \( m, n \in \mathbb{N}, n \geq 3 \) and assume \( \zeta \in \mathbb{C} \setminus \mathbb{R}_{\geq 0} \). Then, for \( 1 \leq p, \bar{p}, q \leq \infty \) such that
\begin{align}
1 \geq \frac{1}{p} &> \frac{n+1}{2n}, \quad 0 < \frac{1}{q} < \frac{n-1}{2n}, \quad \frac{2}{n+1} \leq \frac{1}{p} - \frac{1}{q} < \frac{2}{n}, \\
0 < \frac{1}{p} &< \frac{1}{q} < \frac{1}{n}, \quad \frac{1}{p} \notin \left\{ \left( \frac{1}{n} - \frac{1}{n} \right), \left( \frac{1}{n}, 0 \right) \right\},
\end{align}
(47)
\[ R_0(\zeta) \partial_j f \text{ is a bounded linear operator from } L^p(\mathbb{R}^n; \mathbb{C}^m) \text{ to } L^q(\mathbb{R}^n; \mathbb{C}^m) \text{ satisfying}
\]
\[ \|R_0(\zeta) \partial_j f\|_q \lesssim |\sigma|^{\frac{p}{2} - \frac{n}{2}} \|f\|_p + |\sigma|^{\frac{p}{2} - \frac{n}{2} - \frac{1}{2}} \|f\|_p, \quad j = 1, 2, \ldots, n. \]
(48)
Moreover, there are bounded linear operators \( R_0(\lambda \pm i \bar{\lambda}) \partial_j : L^p(\mathbb{R}^n; \mathbb{C}^m) \to L^q(\mathbb{R}^n; \mathbb{C}^m) \) such that \( R_0(\zeta) \partial_j f \to R_0(\lambda \pm i \bar{\lambda}) \partial_j f, \ j = 1, 2, \ldots, n \) as \( \zeta \to \lambda \pm i \bar{\lambda}, \lambda \in \mathbb{R}_{>0} \) for all \( f \in L^p(\mathbb{R}^n; \mathbb{C}^m) \) and
\[ \|R_0(\lambda \pm i \bar{\lambda}) \partial_j f\|_q \lesssim |\lambda|^\frac{p}{2} \|f\|_p + |\lambda|^\frac{p}{2} \|f\|_p, \quad (\lambda > 0). \]

**Proof.** We first isolate the singularity (in Fourier space) of the Fourier multiplier \( \frac{1}{|\xi|^2 - \zeta} \). In order to do that we introduce the cut-off function \( \chi \in C_0^\infty(\mathbb{R}^n) \) with \( \chi(\xi) = 1 \) whenever \( |\xi| \leq 2 \) and we define \( \chi_\zeta(\xi) := \chi(|\xi|^{-\frac{1}{n}}) \). We then write
\[ R_0(\zeta)(\partial_j f) = F^{-1} \left( \frac{\chi(\xi)(i\xi_j \hat{f}(\xi))}{|\xi|^2 - \zeta} \right) + F^{-1} \left( \frac{(1 - \chi(\xi))(i\xi_j \hat{f}(\xi))}{|\xi|^2 - \zeta} \right) \]
(49)
Observe that \( \chi_\zeta \) is nontrivial in a neighborhood of the sphere of radius \( \zeta \), on the contrary \( 1 - \chi_\zeta \) vanishes in the same neighborhood. In other words, the singularity of the multiplier affects only the first term of the right-hand side of (49). The latter can be estimated with the aid of Theorem 6. More specifically, one has
\[ \left\| F^{-1} \left( \frac{\chi(\xi)(i\xi_j \hat{f}(\xi))}{|\xi|^2 - \zeta} \right) \right\|_q \lesssim |\xi|^{-\frac{1}{n} - \frac{1}{2}} \left\| F^{-1} \left( \frac{\chi(\xi)(i\xi_j \hat{f}(|\xi|^{-1/2})\xi_j)}{|\xi|^2 - \zeta} \right) \right\|_q \]
\[ \lesssim |\xi|^{-\frac{1}{n} - \frac{1}{2}} \left\| F^{-1} \left( \chi(\xi) \hat{f}(|\xi|^{-1/2}) \right) \right\|_p \]
\[ \lesssim |\xi|^{-\frac{1}{n} - \frac{1}{2}} \left\| \hat{f}(|\xi|^{-1/2}) \right\|_p \]
\[ \lesssim |\xi|^{\frac{1}{2} - \frac{n}{2}} \left\| \hat{f} \right\|_p. \]
Here we used Young’s convolution inequality and that \( F^{-1}(\chi(\xi) \xi_j) \) is integrable (being a Schwartz function).
We now turn to the estimate of the second term in the sum in (19). We shall use that
\[ m(\xi) := \frac{(1 - \chi(\xi))\chi_0}{\|\xi\|^2 - \xi_j/|\xi|}, \quad j = 1, 2, \ldots, n, \]
\[ \text{is a } L^r(\mathbb{R}^n) - L^r(\mathbb{R}^n) \text{ multiplier for } 1 < r < \infty, \text{ due to the simplified version of the Mikhlin-Hörmander Theorem stated in Theorem 28.} \]
Recall that \( \chi \) satisfies \( 1 - \chi \equiv 0 \) on a neighborhood of the unit sphere. Notice that, by (47) we have \( 0 < \frac{1}{q} < 1 \) or \( 0 < \frac{1}{p} < 1 \). In the case \( 0 < \frac{1}{q} < 1 \) we use the above observation for \( r = q \) and Theorem 29 implies
\[ F^{-1}\left( \frac{(1 - \chi(\xi))(i\xi_0 f(\xi))}{|\xi|^2 - \frac{1}{\xi_j/|\xi|}} \right) = |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| \mathcal{F}^{-1}\left( \frac{(1 - \chi(\xi))\chi_0}{|\xi|^2 - 1} \mathcal{F}(f(|\xi|^{-1/2})(\xi)) \right) \right\|_q \]
\[ = |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| \mathcal{F}^{-1}\left( m(\xi)\mathcal{F}(F^{-1}\left( \frac{1}{\sqrt{|\xi|^2 + 1}} \mathcal{F}(f(|\xi|^{-1/2})(\xi)) \right)) \right) \right\|_q \]
\[ = |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| \mathcal{F}^{-1}\left( m(\xi)\mathcal{F}(J_1[f(|\xi|^{-1/2})(\xi)]) \right) \right\|_q \]
\[ \lesssim |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| J_1[f(|\xi|^{-1/2})] \right\|_q \]
\[ \lesssim |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| f(|\xi|^{-1/2}) \right\|_{\tilde{p}} \]
\[ \lesssim |\xi|^{-\frac{n}{2} - \frac{1}{q}} \left\| f(|\xi|^{-1/2}) \right\|_{\tilde{p}} \]
In the complementary case \( 0 < \frac{1}{p} < 1 \), we use the Mikhlin-Hörmander Theorem 28 for \( r = \tilde{p} \) and proceed similarly. Plugging the two previous bounds in (19) gives (28). The final part of Theorem 30 can be proved as in Theorem 6.

\[ \square \]
