**Introduction**

The immune system of malaria infected host undergoes both activation and suppression during different phases of parasite’s life cycle. In *Plasmodium chabaudi* chabaudi (AS), T helper cells of host have been reported to be necessary for inducing a protective immune response against the blood stages of parasite [1]. T cells provide protection to infection by cytokine-mediated mechanisms or through production of antibodies. Experiments with B cell deficient mice have demonstrated that B cells and antibodies are essential for complete protection to infection by cytokine-mediated mechanisms or through production of antibodies. Experiments with B cell deficient mice have demonstrated that B cells and antibodies are essential for complete clearance of parasites from blood of the host [2]. Depending upon the cytokines secreted by the Helper T cells, they are classified into two subpopulations: Th1 and Th2 cells. Th1 cells primarily release IFN-γ, IL-2, whereas, Th2 cells secrete IL-4, IL-5, IL-6, IL-10 and IL-13.

CD4+ T cells play an important role in conferring protective immunity towards the liver stages of the malaria parasite [3]. CD4+ T cells stimulate B cells to induce significant level of antimalarial antibody response and also help in the induction of CD8+ T cell responses which help in arresting the growth of liver-stage parasites in the host. It has also been reported that protective immunity can be transferred to naïve hosts by transfer of immune CD4+ T cells [4].

CD4+ CD25+ FoxP3+ regulatory T cells (Tregs) are also involved in the mechanism of immune regulation against *Plasmodium* infection. This subset of T cells play critical role in maintaining immune homeostasis and controlling excessive immune responses [5]. Natural Treg cells during primary exposure to malaria enhanced Th1 memory responses and increased disease severity during re-infection. It also resulted in improved control of parasite burden by the host [6].

CD8+ T cells have been reported to be essential for protective immunity against liver-stage malaria [7]. People living in a malaria-endemic area have been reported to have CD8+ T-cell clones that proliferate and produce IFN-γ in response to blood-stage malarial antigens in an HLA-restricted manner [8]. IFN-γ produced by the T cells as well as NK cells plays a critical role in regulating the protective immune response against blood stage malaria infection [9]. Splenomegaly is common symptom of malaria in both humans and murine models. The spleen removes parasitized red cells from the circulation along with providing a strong hematopoietic response during acute infection.

**Materials and Methods**

**Experimental design**

Four groups of mice are used. Group–I: Normal BALB/c mice-15; Group-II and III: 1 × 10⁶ *P. berghei* infected BALB/c mice/ Placebo control BALB/c mice-35; Group-IV: Immunized BALB/c mice-35. Total animals equals to 85.

| Groups               | Name of groups                      | Animals used |
|----------------------|-------------------------------------|--------------|
| GP-I                 | Normal BALB/c mice                  | 15           |
| GP-II/GP-III         | 1 × 10⁶ *P. berghei* infected BALB/c mice/ Placebo control BALB/c mice | 35 |
| GP-JV                | Immunized BALB/c mice               | 35           |
| Total animals        |                                     | 85           |

**Table 1:** Experimental design.

**Animals and parasite infection**

Inbred BALB/c mice of either sex (5to 6weeks old), weighing 20-25 g procured from IMTECH (Institute of Microbial Technology), Chandigarh, have been used as experimental model. Animals were given pellet feed and water. Guidelines approved by the Institutional Animal Ethics Committee (45/99/CPCSEA) of the Panjab University, Chandigarh have been followed for care and handling of animals. *P. berghei* (NK-65) was maintained in BALB/c mice by intra-peritoneal (i.p) inoculation of 1 × 10⁶ infected erythrocytes from parasitized to normal mice. Giemsa- stained thin blood smears were studied to check course of parasitemia [10].

**Isolation of cell free parasite**

Cell free parasites were obtained from infected blood after saponin lysis and repeated washing in phosphate buffered saline, PBS, pH 7.2
Immunophenotyping of spleen Mononuclear cells (MNCs)

Mononuclear cells were extracted from spleen of control and mice immunized with total parasite antigens were processed for T-regulatory cell analysis. Antibodies viz; anti mouse CD4* (FITC conjugated, 0.5 mg/ml), CD25* (APC conjugated, 0.2 mg/ml), FoxP3* (PE conjugated, 0.2 mg/ml) were purchased from BD BIOSCIENCES, SINGAPORE. Samples were analyzed using BD FACS DIVA software on flow cytometer (FACS CALIBAR BD) after collecting 10,000 events in CSIF at PGIMER, Chandigarh. The results were analyzed using BD FACS DIVA software [16].

Regulatory T cell analysis

Mononuclear cells were extracted from spleen of control and mice immunized with total parasite antigens were processed for T-regulatory cell analysis. Antibodies viz; anti mouse CD4* (FITC conjugated, 0.5 mg/ml), CD25* (APC conjugated, 0.2 mg/ml), FoxP3* (PE conjugated, 0.2 mg/ml) were purchased from BD BIOSCIENCES, SINGAPORE. Samples were analyzed using BD FACS DIVA software on flow cytometer (FACS CALIBAR BD) after collecting 10,000 events [17].

Indirect fluorescent antibody (IFA) test

Level of anti-malarial antibody was tested in sera of immunized and control mice. Serum samples were diluted by two fold serial dilutions using PBS (0.15 m, pH 7.2). Slides were counter stained in 0.5% w/v Evan’s blue in PBS, pH 7.2 to remove any non-specific fluorescence. The highest serum dilution that gave detectable fluorescence (LEICA DMLS, GERMANY) was termed as end point [18].

Quantification of Th1 immune response

For Th1 immune response, level of IgG2a was determined by ELISA. Goat anti-mouse IgG2a isotype specific HRP conjugated secondary antibody was added to the plate.

IL-2 and IFN-γ levels were assayed using commercial cytokine ELISA kits [DIACLONE, FRANCE], Primary monoclonal antibodies (DIACLONE, FRANCE) specific to respective cytokine and secondary biotin-conjugated anti-mouse cytokine specific monoclonal antibodies (BENDER MEDSYSTEMS, AUSTRIA) were used. Streptavidin peroxidase and tetrathymethylbenzidine (TMB) have been used as substrate. The absorbance was read at 450 nm [19,20].

Quantification of Th2 immune response

For Th2 immune response, level of IgG1 was determined by ELISA. Goat anti-mouse IgG1 isotype specific HRP conjugated secondary antibody was added to the plate.

IL-4 and IL-10 levels were assayed using commercial cytokine ELISA kits [DIACLONE, FRANCE], Primary monoclonal antibodies (DIACLONE, FRANCE) specific to respective cytokine and secondary biotin-conjugated anti-mouse cytokine specific monoclonal antibodies (BENDER MEDSYSTEMS, AUSTRIA) were used. Streptavidin peroxidase and tetrathymethylbenzidine (TMB) have been used as substrate. The absorbance was read at 450 nm [19,20].

Statistical Analysis of Data

Data collected from various experiments was subjected to statistical analysis. Mean ± SD of five mice has been used to obtain data for each experiment. Student’s t test has been applied to determine the statistical significance and inter group difference of various parameters. Data of the immunized and control groups have been compared and the p value<0.005 has been termed as statistically significant value.

Results

Post challenge course of parasitemia in immunized mice

![Figure 1: Course of parasitaemia in GP-II, GP-III and GP-IV groups of mice after injection with 1 × 10⁶ P. berghei infected cells.](image)

The parasitemia was determined by examining Giemsa stained blood smears of individual mice daily after injection. Parasitemia (mean ± S.D.) of the immunized and control mice is plotted vs. days post-infection.

In GP-IV group parasite appeared on D3 post challenge (PC), maximum infection (10.28 ± 1.01%) was observed on D12 (PC). No
parasite was observed in blood smear after D18 and all the animals of immunized group survived the challenge, whereas, in Placebo control group (GP-III), parasite appeared on D2 (PI) and typical P. berghei infection pattern was observed as in GP-II. Maximum infection of 43.56 ± 2.21% was recorded on D8 (PI). All the animals of control group died by D9 (Figure 1).

Flow cytometry analysis of control and immunized spleen MNCs

The frequencies of CD3+, CD4+ and CD8+ T cells were found to be increased in immunized mice as compared to controls. 

**CD3+ cells:** The percentage of CD3+ T cells was found to be significantly higher (p<0.005) in mice immunized with TPA as compared to controls. There was a two fold increase in CD3+ T cells in the spleen of immunized mice after challenge on D1 followed by decline on D3 (PC) and remained higher after that till D9 (PC). Whereas, in placebo controls, higher frequencies of CD3+ T cells was observed on D1 (PC), which declined on D3 (PC) followed by increase on D7 (PC) before declining sharply on D9 (PC) after which all the mice of control group died (Figures 2 and 3).

![Figure 2: Flow cytometry of CD3+, CD4+, CD8+ T-cells in normal and infected spleen of BALB/c mice. Isolated MNCs of normal and P. berghei (NK-65) infected spleen were stained with antibody viz. Anti-mouse CD3 (FITC conjugated), CD4 (PE conjugated) and CD8 (APC conjugated). Significant variation in the frequencies of CD3+, CD4+, CD8+ T cells was observed with rise in parasitemia, Data expressed are the mean ± S.D. of the percentage of various cells.](image)

**CD4+ cells:** Spleen of TPA immunized mice exhibited statistically significant (p<0.005) higher percentage of CD4+ T cells as compared to controls. In immunized mice, CD4+ T cells were higher (p<0.005) till D9 (PC) as compared to controls. Due to the weak Th2 immune response, all the control died, whereas, immunized mice which had higher frequencies of CD4+ T cells generated strong Th2 immune response leading to complete survival in this group. Increase in the CD4 T cells in controls was also observed on D3 (PC) and D9 (PC) but it was not significant enough to provide protection (Figures 2 and 3).

**CD8+ cells:** In TPA immunized mice statistically significant (p<0.005) higher percentage of CD8+ T cells was recorded as compared to controls. CD8+ T cells were found to be significantly high (p<0.005) till D9 (PC), whereas, in infected controls CD8+ T cells were found to be high on D1 (PC) and D7 (PC) which gradually declined on D9 (PC). After parasite clearance (D20) the percentage of CD8+T cells returned back to the normal in immunized group also (Figures 2 and 3).

![Figure 3: Flow cytometry of various T cell populations in spleen of GP-IV. Isolated MNCs of immunized spleen were stained with antibody viz. Anti-mouse CD3 (FITC conjugated), CD4 (PE conjugated) and CD8 (APC conjugated). Estimation of total lymphocytes and subset analysis was performed on various days of experiment. Data expressed are the mean ± S.D. of the percentage of various cells.](image)

**CD4+ T regulatory cell analysis:** In TPA immunized spleen, the frequencies of CD4+ Treg cells were found to be significantly (p<0.005) declined as compared to controls.

![Figure 4: Flow cytometry of CD4+Tregs in normal, infected and immunized BALB/c mice spleen. Isolated MNCs of normal, P. berghei (NK-65) infected and immunized spleen were stained with antibody viz. Anti CD4 (FITC conjugated), Anti CD25 (APC conjugated) and Anti FoxP3 (PE conjugated). Estimation of CD4+ Tregs analysis was performed on various days (D0, D1, D3, D5 and D7) of experiment. Data expressed are the mean ± S.D. of the percentage of CD4+ Treg cells.](image)
In immunized group percentage of CD4+Treg cells decreased on D6 (PC), whereas, in controls the percentage of CD4+ Treg cells increased on D1 (PC) and remained high. All the mice of this group died due to D9 (PI). However, lower frequencies of CD4+ Treg cells were observed in GP-IV on D6 (PC) as compared to controls, indicating towards the stimulation of humoral immune response evident from increased CD4+ T cells also. After parasite clearance (D20), CD4+ Treg cell were observed to be increased, whereas, number of CD4+ T cells reduced (Figure 4).

Immunofluorescence Assay (IFA)

Antimalarial antibodies raised against TPA were found to be specific for parasite because fluorescing structure corresponded to *P. berghei* infected cells as observed under phase contrast microscope (Figure 5). 

![Image of Immunofluorescence Assay](image)

**Figure 5: Antibody titers observed in sera of mice immunized with TPA of *P. berghei* by IFA assay.** BALB/c mice were immunized with TPA of *P. berghei* emulsified in FCA on day 0 and FIA on D14 and D28. Animals immunized with PBS and adjuvant alone was termed as placebo control. Animals were challenged with $1 \times 10^6$ parasitized erythrocytes on day 7-post final immunization. Serum obtained was serially diluted in two fold dilutions and end-point titers were determined as the highest serum dilutions giving detectable fluorescence.

Antibody titre of 1:2048 was observed in pre challenge immune serum obtained from GP-IV mice. It increased to 1:4096 after challenge of immunized mice with live parasite on D6 and D12 (PC). After clearance of parasite on D20 (PC), 1:2048 antibody titre was recorded in sera of immunized animals.

**Quantification of Th1 Immune Response**

Statistically significant (p<0.005) higher level of IgG2a was observed on D6 (PC) in mice immunized with TPA as compared to controls. IgG2a was found to be increased till D9 (PC) and declined after parasite clearance (Figure 6).

TPA immunized mice showed significantly higher (p<0.005) levels of IL-2 and IFN- γ as compared to controls (Figure 7). Statistically significant increase in the levels of IL-4 and IL-10 in immune sera as compared to controls point towards the generation of Th2 response.

**Discussion**

T-cells play an important role in protecting host and for disease pathogenesis during infection with *Plasmodium*. T cells are required to eliminate parasite which is hidden inside host cells and thereby evade host’s defence. In response to infection, antigen-specific T and B cells are generated in spleen which contains a large amount of immune cells [21].
B-cells plays significant role in inducing Th2 response and shutting down Th1 response. In self-clearing P. chabaudi strain, efficient clearance of erythrocytic stages is dependent on the presence of B-cells or antibodies [22]. CD4+ T cells have been reported to mediate protective immunity to control blood stage parasites especially in parasite clearance [23]. In P. chabaudi infected spleen the frequencies of CD4+ and CD8+ T cells were reported to be significantly increased on D6 (post infection) which dropped on D12 (post infection) and then increased again after parasite clearance (D18), thereafter the percentages of CD4+T cells approached normal levels [22].

In present study also, spleen of infected mice showed a significant increase in the frequencies of CD4+ T cells indicating the generation of humoral response in host but it was not significant enough to impart protection, whereas, in immunized animals the significant increase was observed in the frequencies of CD4+ T cells and all mice of this group survived. After parasite clearance (GP-IV) the frequencies of CD4+ T cells returned to normal.

CD8+ T cells have been reported to protect the host from blood-stage malaria primarily via secretion of IL-12, IFN-γ, Tumor necrosis factor. In present data, CD8+ T cells in spleen of infected control mice significantly increased on D1 (PI) followed by decline. However, in TPA immunized spleen CD8+ T cells were significantly higher and remained higher till D9 (PC). It has been also observed that TPA immunized mice had significantly (p<0.005) lower parasitemia as compared to control animals indicating a cell mediated immune response. Moreover, latency was longer in TPA immunized mice as compared to control mice.

Treg cells have been reported to be immunosuppressive through the secretion of suppressive cytokines such as TGF-β and IL-10 [24]. Depletion of Tregs, resulted in alleviated malaria-induced inhibition of T-cell proliferation and IL-2 secretion and correlated with significantly reduced IL-10 responses, suggesting that Treg cells could be mediating their suppressive activity during infection through the production of this cytokine.

Earlier it has been reported that in P. chabaudi AS infection in spleen showed a significant increase in CD4+/CD25+Foxp3+ T cells, which was followed by a significant and sustained decrease in their number due to reduced proliferation and apoptosis of CD4+Foxp3+ T cells [25]. In present study also, significant increase was observed in frequencies of Treg cells in control groups, whereas, in immunized mice, lower frequencies of Treg was recorded. In ANKA strain of Plasmodium berghei, Treg depletion resulted in a higher frequency of memory cells developing in the absence of Treg cells [26]. Present study also reports higher frequencies of CD4+ T cells and lower frequencies of CD4+ Treg cells in immunized group.

Elevated frequencies of CD4+ T cells in immunized group were evaluated for induction of Th1 and Th2 response by cytokine profiling. IgG2a has been reported to be involved in antibody mediated protection against P. berghei [27]. In previous study of our laboratory, significant higher levels of IgG1 isotype along with increased level of IgG2a antibody in 43 and 48kdA immunized group are correlated with the mixed Th1/Th2 cytokine profile [28]. Results of present study demonstrate that immunized animals has significant (p<0.005) rise in IgG1 level whereas, IgG2a levels significantly (p<0.005) increased on D1 (PC) till D9 (PC), then declined on D12 (PC) which points towards the mixed Th1/Th2 immune response. This indicates that immunization activated both Th1/Th2 subpopulations of T helper cells.

Further cytokines such as IFN-γ, IL-2, IL-4 and IL-10 were analyzed to differentiate between the Th1 and Th2 immune response. In our previous laboratory studies, significant higher level of IL-4 in ML-1 (55, 64, 66 and 74 kDa) immunized sera, correlated towards the complete protection in TPA immunized mice on D1 (PC) till D9 (PC) as compared to infected control mice in present study also indicate towards the higher antibody titres which provide complete protection to the host.

IL-10 induces B cell proliferation, plasma cell differentiation, development and maturation of antimalarial antibodies [29]. In our studies, significantly high (p<0.005) level of IL-10 was observed in TPA immunized mice on D9 (PC) which significantly declined on D20.

In previous studies, significantly higher levels of IFN-γ in ML-1 immunized mice have been reported to be involved in protection of mice against P. berghei challenge [11]. In accordance with this study, significantly (p<0.005) higher level of IL-10 on D9 (PC) in immune sera of TPA immunized mice point towards the complete protection and survival of mice. IL-2 helps in expansion of antigen-specific T cells and also mediates multiple immune responses on a variety of cell types including thymocytes, activated B cells, monocytes, natural killer cells and oligodendrocytes [29].

It has also been reported that IL-2 in 10,000 g immunized mice is involved in lowering the parasitemia, in P. berghei infection [11]. Significant elevated level of IL-2 on D9 (PC). In our study also indicate towards the complete protection in TPA immunized mice. In P. chabaudi infection the switch in T helper cells response have been reported during peak parasitemia and correlates with symptoms of anaemia [22]. In another study, in P. chabaudi infected serum, secretion of IL-2 has been reported to be declined on D9 (post infection) [25], in our study also, the elevated level of IL-2 declined on D12 (PC) in immunized sera, pointing towards the switch from Th1 to Th2 immune response.

In conclusion, our data showed that weak Th1 and Th2 immune responses are generated in P. berghei infected mice. Weak cell mediated immune response lead to the death of all control animals. However, in immunized mice, a strong humoral as well as cell mediated immune response was observed leading to the complete protection of the mice confirmed by the increased frequencies of CD4+ and CD8+ T cells and their respective cytokines. Treg cells which are involved in pathogenesis of disease are also higher in control groups as compared to immunized.

Acknowledgment

It is a pleasure to acknowledge the technical work of CSIF for immunophenotyping by flow cytometer (FACS Calibar B.D.) at PGIMER, Chandigarh. Authors are also thankful to University Grant Commission, New Delhi for providing financial assistance under UGC-Major Research Project.
