(Dated: June 1, 2020)

Based on ab initio relativistic $k \cdot p$ theory, we derive an effective two-band model for surface states of three-dimensional topological insulators up to seventh order in $k$. It provides a comprehensive description of the surface spin structure characterized by a non-orthogonality between momentum and spin. We show that the oscillation of the non-orthogonality with the polar angle of $k$ with a $\pi/3$ periodicity can be seen as due to effective six-fold symmetric spin-orbit magnetic fields with a quintuple and septuple winding of the field vectors per single rotation of $k$. Owing to the dominant effect of the classical Rashba field, there remains a single-winding helical spin structure but with a periodic few-degree deviation from the orthogonal locking between momentum and spin.

I. INTRODUCTION

Over the last decade, the effective model Hamiltonian for topological surface states developed in Refs. [1] and [2] is commonly accepted as a tool to include in a simple manner their remarkable features: the linear energy-momentum dispersion and helical in-plane spin structure. This model has been applied to a variety of topologically non-trivial materials in the spirit of the classical Rashba model, which, since the seminal paper by LaShell et al. [3], has been used to fit the two-dimensional (2D) spin-orbit-split states at trivial surfaces. The spin-orbit splitting $k_{\pm}$-linear term is the same for trivial and for topological surface states, and it yields an orthogonal spin-momentum locking commonly considered a hallmark of a strong spin-orbit interaction (SOI).

The simplified model of Refs. [1] and [2] needs to be extended in order to describe the non-orthogonality between spin and momentum in realistic systems, as, e.g., observed in photoemission from Bi$_2$Se$_3$ [4]. While it naturally arises in ab initio calculations, in $k \cdot p$ theory, in order to yield a deviation from orthogonality, an effective Hamiltonian must include higher-order in $k$ spin-orbit terms. In Ref. [5], for structures with the $C_{3v}$ crystal symmetry and time-reversal symmetry it was suggested to include a $k_{\pm}^3$ term to allow for the non-orthogonality, and a minimal fifth-order $k \cdot p$ model was applied to Bi$_2$Te$_3$. Following Ref. [5], in Ref. [6] this model was also used to analyze the spin structure of the Au/Ge(111) surface state, which is rather far from being Rashba-like. Since the fifth-order Hamiltonian was constructed based on symmetry arguments rather than derived directly from ab initio spinor wave functions, its parameters were found by fitting to the ab initio band structure, which is an approximate procedure sensitive to the choice of the energy interval of interest and to the order of the $k \cdot p$ expansion: with each successive order the complexity and ambiguity grow, and the parameters become increasingly less physically meaningful.

Here, we study the angle between the spin and momentum in the surface states of Bi$_2$Se$_3$ and Bi$_2$Te$_2$Se within our ab initio relativistic $k \cdot p$ approach introduced in Refs. [7–9]. This approach has been successfully applied to different materials [9–12] and established as a reliable theoretical tool for deriving few-band $k \cdot p$ Hamiltonians capable of comprehensive description of the surface spin structure. We take Bi$_2$Se$_3$ and Bi$_2$Te$_2$Se as vivid examples of the topological insulators (TIs) with a rather wide absolute bulk band gap bridged by the partly occupied topological surface state and a local projected gap well above the Fermi level hosting the so-called “second topological surface state” [13–17]. The wide gap is favorable for minimizing the effect of the proximity of bulk states on the surface-state spin structure. The presence of the second surface state makes it possible to derive a two-band seventh-order Hamiltonian by applying the Löwdin partitioning to a four-band third-order Hamiltonian generated for the two surface states within our ab initio approach.

For Bi$_2$Se$_3$ and Bi$_2$Te$_2$Se, we derive the seventh-order Hamiltonian allowing for the non-orthogonal locking between momentum and spin. We show that there is an oscillation of the spin around the momentum-perpendicular direction with a $\pi/3$ periodicity as a function of the polar angle of $k$ due to the presence of $k$-dependent effective spin-orbit magnetic fields of the six-fold symmetry. The effective Hamiltonian facilitates the inclusion of the non-orthogonality in the description of spin-related properties of the TI surfaces and their interpretation within $k \cdot p$ theory. Thus, our study can also be considered as an ab initio substantiation of the fifth-order Hamiltonian proposed in Ref. [4], based on an unambiguous algorithm for its parameters.
II. COMPUTATIONAL DETAILS

The ab initio band structure is obtained with the extended linear augmented plane waves method [18] using the full potential scheme of Ref. [19] within the local density approximation (LDA). The spin-orbit interaction was treated as a second variation [20]. The surfaces of the TIs are simulated by bulk-truncated centrosymmetric six-QL (quintuple layer) slabs of space group P3m1 (no. 164). The experimental crystal lattice parameters were taken from Ref. [21]. In the case of Bi₂Te₂Se, the experimental atomic positions of Ref. [21] were used, while for Bi₂Se₃ we took the LDA relaxed atomic positions of Ref. [22].

III. SPIN-MOMENTUM LOCKING ANGLE

Figure 1 shows the calculated LDA band structure of the Bi₂Se₃ and Bi₂Te₂Se surfaces along Γ-K. Two topological surface states are clearly identified in the spectra of both TIs. The two states are numbered n = 1 and 2 in order of increasing energy. The spin-resolved constant energy contours (CECs) at ~ 0.2 eV above the Dirac points of the low-energy surface states (n = 1) are shown in Fig. 2 together with the respective angles of deviation from the orthogonal spin-momentum coupling δ. As a function of the polar angle \( \varphi \) of the momentum \( \mathbf{k} \), the deviation angle demonstrates an oscillating behavior with a \( \pi /3 \) periodicity and an amplitude close to 1.5° for Bi₂Se₃, which is in good agreement with the experiment of Ref. [4], and about 3.0° for Bi₂Te₂Se.

We start with a \( \mathbf{k} \cdot \mathbf{p} \) model comprising both Dirac surface states \( n = 1 \) and \( 2 \). Being eigenfunctions of a centrosymmetric slab Hamiltonian at \( \Gamma \), these states form four Kramers-degenerate pairs with spinor wave functions \( \Psi_{\mu} \), which we group into two twin pairs with two members, \( m = 2n - 1 \) and \( 2n \). Here, \( \mu = \uparrow \) or \( \downarrow \) indicates the sign + or − of the expectation value \( \langle \Psi_{\mu} | \hat{J}_z | \Psi_{\mu} \rangle = \langle J_z \rangle_{mn} \delta_{\mu m} \delta_{\mu \mu'} \) of the z projection of the total angular momentum \( \hat{J} \) at the (symmetry equivalent) atomic sites of type \( \tau \), which has the largest weight \( |\Psi_{\mu} \rangle \langle \Psi_{\mu} | = \langle J_z \rangle_{mn} \). With this basis set, we first microscopically derive an eight-band \( \mathbf{k} \cdot \mathbf{p} \) Hamiltonian \( H_{\mathbf{k} \mathbf{p}} \) from an ab initio relativistic \( \mathbf{k} \cdot \mathbf{p} \) perturbation expansion around the \( \Gamma \) point. The expansion is carried out up to the third order in \( \mathbf{k} \) by applying the Löwdin partitioning [23-25] to the original Hilbert space of the \( \Gamma \)-projected LDA Hamiltonian \( H_{\mathbf{k} \mathbf{p}}^{\text{LDA}} \), see Appendix A.

Because \( \Psi_{\mu} \) are slab eigenfunctions representing the surface states, each twin-pair is characterized by two doubly degenerate slab levels \( E_{2n-1} \) and \( E_{2n} \) separated by \( \Delta_n = E_{2n} - E_{2n-1} \) of a few meV due to the bonding-antibonding interaction. Since the \( \Gamma \) point is a TRIM (time reversal invariant momentum), the spinors \( \Psi_{\mu} \) are also parity eigenfunctions, and the two pairs for a given \( n = 1 \) or \( 2 \) have different parity. We now transfer to a new basis \( |\Psi_{\mu}^{\pm} \rangle = \frac{1}{\sqrt{2}} \left[ |\Psi_{2n-1 \mu} \rangle \pm |\Psi_{2n \mu} \rangle \right] \), where the new basis functions \( |\Psi_{\mu}^{\pm} \rangle \) are no longer parity eigenfunctions but are localized at one of the two surfaces of the 6QL slab, “+” or “−”. In this surface-resolved basis, the original 8 × 8 Hamiltonian reads

\[
H_{\mathbf{k} \mathbf{p}} \rightarrow H_{\mathbf{k} \mathbf{p}}^{\text{film}} = \begin{pmatrix} H_{\text{surf}}^+ & H_{\text{int}}^+ \\ H_{\text{int}}^- & H_{\text{surf}}^- \end{pmatrix} .
\]  

In Fig. 1, the bands obtained by diagonalizing this Hamiltonian are shown by light green lines for both TIs. Further we neglect the coupling of the surfaces due to the overlap between the + and − basis functions, \( H_{\text{int}} \to 0 \), and in the following we will consider only the − surface, so we omit the superscript −. In a compact form, the resulting 4 × 4 Hamiltonian, which is just the term \( H_{\text{surf}}^- \) of the Hamiltonian (1), reads

\[
H_{\mathbf{k} \mathbf{p}}^{4 \times 4} = \begin{pmatrix} E_1 + H_1 + H_1^R & H_0 + \bar{H} \\ H_0 + \bar{H}^\dagger & E_2 + H_2 + H_2^R \end{pmatrix} .
\]  

Here, each term of the diagonal and non-diagonal blocks is a 2 × 2 matrix, whose implicit form directly follows from the ab initio \( \mathbf{k} \cdot \mathbf{p} \) expansion up to the third order in \( \mathbf{k} \): \( E_n = \epsilon_n \alpha_{2x2} \), with \( \alpha_{2x2} \) being the 2 × 2 identity matrix, \( H_n = M_n k^2 \alpha_{2x2} \), \( k = \sqrt{k_x^2 + k_y^2} \), and

\[
H_n^R = \begin{pmatrix} -i W_n (k_+^3 - k_-^3) & i \alpha_n k_- \\ -i \alpha_n k_+ & i W_n (k_+^3 - k_-^3) \end{pmatrix} .
\]
where $\alpha_n = \alpha_n^{(1)} + \alpha_n^{(3)}k^2$ and $k_{\pm} = k_x \pm k_y$. The well-known $2 \times 2$ Rashba term $R_{\tilde{H}}$ is responsible for the out-of-plane and in-plane spin structure typical of hexagonal structures, see, e.g., Ref. [9] and references therein. The interaction between the states $n = 1$ and $2$ is realized through the term

$$\tilde{H} = \left( \begin{array}{cc} i\tilde{\delta}k_x^2 + \rho k_y^2 & i\tilde{\gamma}k_x + Dk_z^2 \\ -i\tilde{\gamma}k_x - Dk_z^2 & i\tilde{\gamma}k_y + \rho k_z^2 \end{array} \right)$$

(4)

with $\tilde{\gamma} = \zeta^{(1)} + \zeta^{(3)}k^2$.

In the new basis, the spin matrix that yields the spin structure of the states under study is defined as

$$S_k^{4 \times 4} = \left( \begin{array}{cc} S_1 & \tilde{S} \\ \tilde{S} & S_2 \end{array} \right)$$

(5)

with $S_n = (s_n^x, s_n^y, s_n^z)$ and $\tilde{S} = (\tilde{s}^x, \tilde{s}^y, \tilde{s}^z)$, where $s_n = (s_x, s_y)$ and $\sigma_{x,y}$ are the Pauli matrices.

The elements of the spin matrix $[S_k^{4 \times 4}]_{\mu \nu} = \langle \Phi_{\mu \nu} | \sigma | \Phi_{\mu \nu} \rangle$ enter into the expression for the spin expectation value

$$\langle S_k^\lambda \rangle = \frac{1}{2} \langle \Phi_k^\lambda | \sigma | \Phi_k^\lambda \rangle = \frac{1}{2} \sum_{\mu \nu} C_{k \mu \nu}^k C_{k \nu \mu}^k \left[ S_k^{4 \times 4} \right]_{\mu \nu}$$

(6)

in the state $| \Phi_k^\lambda \rangle = \sum_{\mu \nu} C_{k \mu \nu}^k | \Phi_{\mu \nu} \rangle$ of the reduced Hilbert space of the Hamiltonian $H_k^{4 \times 4}$. The four-dimensional vectors $C_k^\lambda$ diagonalize this Hamiltonian $H_k^{4 \times 4}$.

| TABLE I. Parameters of the four-band Hamiltonians (2) (based on calculations for 6QL-layer slabs with the lattice parameter $a = 7.8187$ a.u. for Bi$_2$Se$_3$ and $a = 8.0880$ a.u. for Bi$_2$Te$_2$Se). All parameters are in Rydberg atomic units except for $\epsilon_1$ and $\epsilon_2$ presented in eV. |
|-----------------|-----------------|
| Bi$_2$Se$_3$    | Bi$_2$Te$_2$Se  |
| $\epsilon_1$   | $-0.118$        | $-0.278$        |
| $\epsilon_2$   | $1.429$         | $1.053$         |
| $\alpha_1^{(1)}$ | $0.174$         | $0.187$         |
| $\alpha_1^{(3)}$ | $-0.265$        | $-0.150$        |
| $\alpha_2^{(1)}$ | $28.30$         | $29.03$         |
| $\alpha_2^{(3)}$ | $141.80$        | $22.35$         |
| $\theta$       | $8.33$          | $22.39$         |
| $\eta$         | $-1.02$         | $-3.00$         |
| $\zeta^{(1)}$  | $-0.048$        | $-0.078$        |
| $\zeta^{(3)}$  | $-52.83$        | $4.51$          |
| $D$            | $-2.64$         | $-3.40$         |
| $M_1$          | $7.97$          | $15.67$         |
| $M_2$          | $-2.56$         | $-1.76$         |
| $M_0$          | $-0.37$         | $0.61$          |
| $W_1$          | $-4.71$         | $-17.32$        |
| $W_2$          | $5.53$          | $11.88$         |
| $s_1^x$        | $0.70$          | $0.63$          |
| $s_2^x$        | $0.42$          | $0.39$          |
| $s_3^x$        | $0.40$          | $0.26$          |
| $s_1^y$        | $-0.16$         | $-0.21$         |
| $s_2^y$        | $-0.21$         | $-0.10$         |
| $s_3^y$        | $-0.41$         | $-0.20$         |
The parameters in Eqs. (2) and (5) are listed in Table I. The bands obtained with these parameters are shown in Fig. 1 by green lines.

Next, we analytically transform the Hamiltonian (2) by means of the Löwdin partitioning, retaining terms up to seventh-order in \( k \) for the block \( E_1 + H_1 + H^{\parallel}_1 \) of this Hamiltonian. As a result, we arrive at the \( 2 \times 2 \) Hamiltonian that describes the low-energy Dirac surface state:

\[
H^{2 \times 2}_{kp} = \left( \begin{array}{cc} \epsilon_1 + \mathcal{M} k^2 - i\mathcal{W}(k^3 - k^3_z) + \mathcal{N}(k^6 + k^6_z) - i\tilde{\alpha} k_z + i\tilde{\gamma} k^5_z - i\xi k^7_z & \epsilon_1 + \mathcal{M} k^2 + i\mathcal{W}(k^3 - k^3_z) + \mathcal{N}(k^6 + k^6_z) \\ i\tilde{\alpha} k_z - i\tilde{\gamma} k^5_z + i\xi k^7_z & \epsilon_1 + \mathcal{M} k^2 - i\mathcal{W}(k^3 - k^3_z) + \mathcal{N}(k^6 + k^6_z) \end{array} \right),
\]  

where \( \mathcal{M} = \sum_{m=0}^{\infty} M^{(2m)} k^{2m} \), \( \mathcal{W} = \sum_{m=0}^{\infty} W^{(2m)} k^{2m} \), \( \tilde{\alpha} = \alpha^{(1)}_1 + \sum_{m=1}^{\infty} \alpha^{(2m+1)} k^{2m} \), and \( \tilde{\gamma} = \gamma^{(5)} + \gamma^{(7)} k^2 \), see Appendix B. All the parameters are listed in Table II. With these parameters, the diagonalization of the Hamiltonian (7) yields the bands shown by dark green lines in Fig. 1.

Up to fifth order in \( k \), the Hamiltonian (7) of our \textit{ab initio} \( k \cdot p \) theory is in accord with the form of the two-band Hamiltonian constructed in Ref. [5] for Bi\(_2\)Te\(_3\) considering the \( C_{3v} \) crystal symmetry and time-reversal symmetry. In Ref. [6], the Hamiltonian of Ref. [5] was modified by adding a sixth-term order \( k^6 + k^6_z \) in order to reproduce the hexagonal warping of the Au/Ge(111) surface state not related to the spin-orbit effect. Obviously, this term is naturally present in our theory. Note that in Refs. [5] and [6] the values of the parameters were found by fitting the model Hamiltonian to \textit{ab initio} results, and, for example, in the case of the surface state of Bi\(_2\)Te\(_3\) [5] the values for the lower-order terms differ strongly from those obtained in Refs. [2] and [7], which are currently commonly accepted. In contrast to a fitting method, in our \( k \cdot p \) theory the shape and the value of a given order term are independent on whether or not we include higher-order terms (and it does not affect the lower-order terms), since our \( k \cdot p \) expansion uniquely follows from the basis set—the eigenfunctions of the original \textit{ab initio} Hamiltonian.

The spin-resolved CECs and the non-orthogonality by our \( k \cdot p \) model are shown in Fig. 2. As seen in the figure, the effective model underestimates the non-orthogonality for the lower-energy Dirac surface states. A better agreement with the respective \textit{ab initio} results is achieved by increasing the magnitude of \( \gamma^{(5)} \) by a factor of 4.5 (\( \gamma^{(5)} = 2382.3 \) a.u.) and 3.8 (\( \gamma^{(5)} = 6596.4 \) a.u.) for Bi\(_2\)Se\(_3\) and Bi\(_2\)Te\(_2\)Se, respectively, see the orange areas and curves in Fig. 2 (the respective energy bands are shown by orange lines in Fig. 1). Note that by manually correcting this parameter we reproduce more accurately not only the non-orthogonality, but also the hexagonal warping of the contours.

### Table II. Parameters of the two-band Hamiltonians (7) in Rydberg atomic units. The parameters \( \epsilon_1, \alpha^{(1)}_1, s^i_1, s^i_3, \) and the lattice parameters \( a \) are listed in Table I.

|         | Bi\(_2\)Se\(_3\) | Bi\(_2\)Te\(_2\)Se |
|---------|-------------------|-------------------|
| \( \alpha^{(3)} \) | 27.91             | -28.27            |
| \( \alpha^{(5)} \) | -575.48           | 115.57            |
| \( \gamma^{(7)} \) | -92731.72         | 63344.71          |
| \( \gamma^{(5)} \) | 529.40            | 1735.90           |
| \( N \)     | -157.85           | -789.83           |
| \( M^{(6)} \) | 7.95              | 15.61             |
| \( M^{(2)} \) | -110.14           | -122.40           |
| \( M^{(4)} \) | -36925.53         | -27778.63         |
| \( W^{(0)} \) | -5.82             | -20.03            |
| \( W^{(2)} \) | -1389.00          | -162.47           |
| \( W^{(4)} \) | -111467.25        | 65344.75          |

### IV. EFFECTIVE FIELDS AND MULTIPLE WINDING

We focus now on the terms of the \( 2 \times 2 \) Hamiltonian that cause the non-orthogonality in the in-plane-spin structure. We rewrite the Hamiltonian (7) in terms of the Pauli matrices:

\[
H^{2 \times 2}_{kp} = \mathcal{E}(k) \sigma_0 + \mathbf{B} \cdot \mathbf{\sigma},
\]

where \( \mathcal{E}(k) = \epsilon_1 + \mathcal{M} k^2 + 2N k^6 \cos \phi_k \) represents the dispersion of the doubly degenerate bands with the hexagonal warping of their CECs. The SOI-induced splitting of the bands

\[
E^\pm(k) = \mathcal{E}(k) \pm |\mathcal{B}|
\]

is due to the Zeeman-like term with the effective (spin-orbit) magnetic field

\[
\mathcal{B} = \bar{\alpha} \mathcal{B}_R^{(1)} + 2W \mathcal{B}_Z^{(3)} + \tilde{\gamma} \mathcal{B}_Z^{(5)} + \xi \mathcal{B}_Z^{(7)}.
\]

This field consists of the classical (linear) Rashba magnetic field \( \mathcal{B}_R^{(1)} = k(\sin \phi_k, -\cos \phi_k, 0) \), the cubic field \( \mathcal{B}_Z^{(3)} = k^3(0, 0, \sin 3\phi_k) \) responsible for the well-known
three-fold symmetric pattern of the spin $z$ component and contributing to the hexagonal warping of the CECs [26], and two higher-order six-fold symmetric fields $\mathbf{B}^{(5)} = k^5(\sin 5\varphi_k, \cos 5\varphi_k, 0)$ and $\mathbf{B}^{(7)} = k^7(\sin 7\varphi_k, -\cos 7\varphi_k, 0)$, see Fig. 3. Note that since the spin matrix $(s^\dagger_1 \sigma_z, s^\dagger_2 \sigma_z)$ of our two-band $k \cdot p$ model (the upper-left $2 \times 2$ block of the spin matrix (5)) differs from the matrix $(\sigma_z, \sigma_z)$ of a model built on a scalar-relativistic basis only by the non-unity coefficients $s^\dagger_1$ and $s^\dagger_2$, one is tempted to treat the Pauli matrices in Eq. (8) as if they were spin matrices. Then, the spin expectation value is $\mathbf{S}^\pm(k) = \pm \frac{1}{2} \mathbf{B}/|\mathbf{B}|$. However, irrespective of the interpretation of $\sigma$ in Eq. (8), in our model the non-orthogonality is characterized by the deviation angle $\delta^\pm$ found from the dot product

$$\sin \delta^\pm = \frac{\mathbf{S}^\pm(k) \cdot \mathbf{k}}{|\mathbf{S}^\pm(k)| |\mathbf{k}|} = \pm \frac{k^5}{|\mathbf{B}|} (\gamma + \xi k^2) \sin 6\varphi_k,$$

where the parallel (in-plane) component of the effective field (10) is

$$|\mathbf{B}|^2 = (\tilde{\alpha}^2 + \tilde{\gamma}^2 k^8 + \xi^2 k^{12}) k^2 - 2\tilde{\gamma} k^8 (\gamma - \xi k^2) \cos 6\varphi_k - 2\tilde{\alpha}^2 k^{12} \cos 12\varphi_k.$$  

We see that the angle $\delta^\pm$ has a non-trivial dependence on the polar angle with a $\pi/3$ periodicity due to the presence of the fields $\mathbf{B}^{(5)}$ and $\mathbf{B}^{(7)}$. Acting separately, these fields may cause a quintuple or a septuple winding of the in-plane spin, respectively, in contrast to the Rashba field $\mathbf{B}^{(1)}_R$ yielding a single winding, Fig. 3.

At a given $k$, the importance of each contribution to the effective magnetic field of Eq. (10) depends on the respective parameter of the Hamiltonian (7): $\tilde{\alpha}$, $\tilde{W}$, $\tilde{\gamma}$ or $\xi$. According to their values in Table II, the effect of the field $\mathbf{B}^{(7)}$ is expected to be negligible, because $\xi$ is much smaller than $\alpha^{(7)}$ and $\gamma^{(7)}$. At the same time, the contribution of $\mathbf{B}^{(5)}$ depends on the parameters $\gamma^{(5)}$ and $\gamma^{(7)}$, which are comparable to or even larger than $\alpha^{(5)}$ and $\alpha^{(7)}$, respectively. However, because of the dominant contribution of the linear Rashba field $\mathbf{B}^{(1)}_R$ due to the rather large $\alpha_1^{(1)}$ in $\tilde{\alpha}$ of Eq. (10), the superposition of all the in-plane fields produces a single winding of the in-plane spin [27].

The in-plane-field contribution (12) as well as the out-of-plane contribution $|\mathbf{B}_Z|^2 = 2W^2 k^6 (1 - \cos 6\varphi_k)$ of the effective field (10) affects the eigenvalues (9) of the Hamiltonian (8) though the splitting term $\pm |\mathbf{B}|$. This means that the SOI-induced hexagonal warping of the CECs is due not only to the cubic field $\mathbf{B}_Z$ as, e.g., in Ref. [26], but also to the fields $\mathbf{B}^{(5)}$ and $\mathbf{B}^{(7)}$, which contribute to the warping through the scalar products $\mathbf{B}^{(5)} \cdot \mathbf{B}^{(1)}_R$ and $\mathbf{B}^{(7)} \cdot \mathbf{B}^{(1)}_R$ [the terms proportional to $\tilde{\alpha}^2$ and $\tilde{\alpha}^2$ in Eq. (12), respectively]. As follows from Tables I and II, the fields $\mathbf{B}_R$ and $\mathbf{B}_Z$ are equally important for the $\cos 6\varphi_k$ distortion of the CEC. In addition, the hexagonal warping due to $\mathbf{B}_Z$ gives rise to the $z$ spin component, so if one neglects the contribution of $\mathbf{B}_Z$ and fits only the cubic field to calculated or measured CECs, one may arrive at a large out-of-plane spin polarization with the spin-momentum locking unaffected by the warping. In contrast, the CEC warping caused by the fields $\mathbf{B}^{(5)}$ and $\mathbf{B}^{(7)}$ is accompanied by a change of the locking angle between spin and momentum. This explains why a stronger warping may imply a larger non-orthogonality.

V. CONCLUSIONS

To summarize, within a fully ab initio $k \cdot p$ perturbation approach we have developed a two-band effective $k \cdot p$ model for the surface states of the three-dimensional topological insulators Bi$_2$Se$_3$ and Bi$_2$Te$_3$Se. The model includes terms to seventh order in $k$ and provides a comprehensive description of the surface spin structure characterized by a non-orthogonality between the surface-electron spin and its momentum. In the $k \cdot p$ theory, the non-orthogonality that arises naturally in the ab initio calculations is included in the effective models through the higher-order terms in $k$. Our $k \cdot p$ expansion builds on the eigenfunctions of the ab initio Hamiltonian, and, therefore, a term of a given order is unambiguously determined by the ab initio spinor wave functions and, in contrast to a fitting method, does not depend on the presence of other terms. We have shown that the $k^4$- and $k^6$-terms represent effective spin-orbit magnetic fields with six-fold symmetric patterns on the two-dimensional momentum plane and, thereby, can lead to a non-orthogonality with the $\pi/3$ periodicity as a function of the polar angle of $k$. For Bi$_2$Se$_3$ and Bi$_2$Te$_2$Se, we have found that the contribution of the $k^6$-term is rather small, and it is the $k^4$-term that causes the few-degree deviation of the actual spin direction from the classical
orthogonality.

Finally, we would like to note that the derived two-band Hamiltonian is fully applicable to classical Rashba systems such as the Au(111) surface state. Here, the non-orthogonality appears to be negligibly small, albeit nonzero. A similar study for the giant Rashba spin-split conduction state of a single BiTeI trilayer reveals a substantial non-orthogonality, rather different for the inner and outer constant energy contour. In fact, the two-band Hamiltonian (7) can be considered typical of hexagonal structures. Thus, the simplified picture that the in-plane spin and momentum are locked perpendicular to each other by spin-orbit interaction might overlook important features inherent in the spin-related phenomena at the surfaces and in 2D structures.

Appendix A: Ab initio third-order \( \mathbf{k} \cdot \mathbf{p} \) expansion

The Löwdin partitioning applied to the original Hilbert space of the LDA Hamiltonian, represents the \( \mathbf{k} \cdot \mathbf{p} \) Hamiltonian in the basis of the chosen spinor wave functions (the states in set \( A \) numbered below by the indices \( n\nu, m\mu \), and \( n'\mu' \)) in terms of the matrix elements of the velocity operator\(^7,28\)

\[
\pi = -i\hbar \nabla + \frac{\hbar}{4m_0 c^2} [\sigma \times \nabla V]
\]

Here, \( \sigma \) is the vector of the Pauli matrices that operate on spinors, and \( V(r) \) is the crystal potential. The \textit{ab initio} third-order \( \mathbf{k} \cdot \mathbf{p} \) expansion at a TRIM in a centrosymmetric system\(^9,12\) reads

\[
H_{\mathbf{k}\mathbf{p}} = H^{(0)} + H^{(1)} + H^{(2)} + H^{(3)},
\]

where the zero-order term is just the band energy,

\[
H^{(0)} = \epsilon_n \delta_{m\nu} \delta_{m\mu},
\]

and the linear term is

\[
H^{(1)} = \frac{\hbar}{m_0} \mathbf{k} \cdot \pi_{n\nu m\mu}
\]

with the matrix elements \( \pi_{n\nu m\mu} = \langle \Psi_{n\nu} | \pi | \Psi_{m\mu} \rangle \). For two Kramers pairs of different parity, \( n\nu \) and \( m\mu \), we turn the phases such that \( i \pi_{n\nu m\mu} \) and/or \( i \pi_{n\nu m\mu} \) be real. The second- and third-order terms are

\[
H^{(2)} = \frac{\hbar^2 k^2}{2m_0} \delta_{m\nu} \delta_{m\mu} + \frac{\hbar^2}{m_0} \sum_{\alpha\beta} k_\alpha k_\beta D^{\alpha\beta}_{n\nu m\mu},
\]

\[
H^{(3)} = \frac{\hbar^3}{m_0^3} \sum_{\alpha\beta\gamma} k_\alpha k_\beta k_\gamma T^{\alpha\beta\gamma}_{n\nu m\mu}
\]

with \( \alpha, \beta, \gamma = x, y, z \). Here, the coefficients are

\[
D^{\alpha\beta}_{n\nu m\mu} = \frac{1}{2} \sum_{l\eta} \pi^\alpha_{n\nu l\eta} \pi^\beta_{l\eta m\mu} \left( \frac{1}{\Delta_{nl}} + \frac{1}{\Delta_{ml}} \right),
\]

\[
T^{\alpha\beta\gamma}_{n\nu m\mu} = -\frac{1}{2} \sum_{l\eta, m'\mu'} \left[ \frac{\pi^\alpha_{n\nu l\eta} \pi^\beta_{l\eta m'\mu'} \pi^\gamma_{m'\mu' l\eta} \pi_{l\eta m\mu}}{\Delta_{ml} \Delta_{ml'} \Delta_{nl}} \right]
\]

\[
+ \frac{1}{2} \sum_{l\eta, l', \eta'} \pi^\alpha_{n\nu l\eta} \pi^\beta_{l\eta l' \eta'} \pi^\gamma_{l' \eta' m\mu} \times \left[ \frac{1}{\Delta_{nl} \Delta_{nl'}} + \frac{1}{\Delta_{ml} \Delta_{ml'}} \right],
\]

where \( \Delta_{nl} = \epsilon_n - \epsilon_l \), and the indices \( l\eta \) and \( l'\eta' \) number the states in set \( B \), i.e., run over all the states of the original Hilbert space excluding those forming the \( \mathbf{k} \cdot \mathbf{p} \) basis—the subspace \( A \).

Appendix B: Parameters of the \( 2 \times 2 \) Hamiltonian

The analytical transformation of the four-band Hamiltonian (2) by means of the Löwdin partitioning leads to the following expressions for the parameters of the two-band Hamiltonian (7):
\[
\alpha^{(3)} = \frac{1}{\Delta_{21}} - \frac{2M_0\zeta^{(1)}_2}{\Delta_{21}^2} \left[ \alpha^{(1)}_1 - \alpha^{(1)}_2 \right],
\]
\[
\alpha^{(5)} = -\frac{2}{\Delta_{21}} [M_0\zeta^{(3)}_2 - \eta D] - \frac{1}{\Delta_{21}} \left( [M_0^2 + 2\zeta^{(1)}_1\zeta^{(3)}_2][\alpha^{(1)}_1 - \alpha^{(1)}_2] + \alpha^{(1)}_2 D^2 + 2M_0\zeta^{(1)}_1[M_1 - M_2] + \zeta^{(3)}_2[\alpha^{(1)}_3 - \alpha^{(3)}_2] \right),
\]
\[
\alpha^{(7)} = \frac{1}{\Delta_{21}} \left( 2[M_1 - M_2] D + \zeta^{(1)}_1(\theta - \eta) \right) + \frac{1}{\Delta_{21}} \left( [\alpha^{(1)}_1 - \alpha^{(1)}_2][M_0^2 + 2\zeta^{(1)}_1\zeta^{(3)}_2] - [\alpha^{(1)}_1 - \alpha^{(1)}_2]^{2} D^2 - \alpha^{(1)}_1(\theta^2 + \eta^2) + 2\alpha^{(1)}_2 \theta \eta \right),
\]

\[
W^{(0)} = W_1 - \zeta^{(1)} D/\Delta_{21},
\]
\[
W^{(2)} = \frac{1}{\Delta_{21}} \left( [M_0(\theta - \eta) - \zeta^{(1)} D] - \frac{1}{\Delta_{21}^2} \left( \zeta^{(1)} D^2 [W_1 + W_2] + \zeta^{(1)} D [M_1 - M_2] + \alpha^{(1)}_2 \zeta^{(1)} [\theta - \eta] - \alpha^{(1)}_1 M_0 D \right) \right),
\]
\[
W^{(4)} = \frac{1}{\Delta_{21}} \left( [\theta - \eta] [M_0(M_1 - M_2) - \alpha^{(1)}_2 \zeta^{(3)} - \alpha^{(3)}_2 \zeta^{(1)}] - \zeta^{(3)} D[M_1 - M_2] \right) - \frac{1}{\Delta_{21}} \left( [M_0^2 W_1 - W_2] + [W_1 + W_2][D^2 + 2\zeta^{(1)} \zeta^{(3)}_2 - \alpha^{(3)} M_0 D] \right),
\]
\[
M^{(0)} = M_1 - \zeta^{(1)} D/\Delta_{21},
\]
\[
M^{(2)} = -\frac{1}{\Delta_{21}} \left( M_0^2 D^2 + 2\zeta^{(1)} \zeta^{(3)}_2 \right) - \frac{1}{\Delta_{21}^2} \left( \zeta^{(1)} D^2 [M_1 - M_2] + 2\zeta^{(1)} M_0 [\alpha^{(1)}_1 - \alpha^{(1)}_2] \right),
\]
\[
M^{(4)} = -\frac{1}{\Delta_{21}} \left( \theta^2 + \eta^2 + \zeta^{(3)} D^2 \right) - \frac{1}{\Delta_{21}^2} \left( [M_1 - M_2][M_0^2 + D^2 + 2\zeta^{(1)} \zeta^{(3)}] \right) - \frac{2}{\Delta_{21}} \left( \zeta^{(3)} M_0[\alpha^{(1)}_1 - \alpha^{(1)}_2] - D(\alpha^{(1)}_1 \eta - \alpha^{(1)}_2 \theta) + \zeta^{(1)} M_0[\alpha^{(3)}_1 - \alpha^{(3)}_2] + \zeta^{(1)} D[W_1 + W_2] \right),
\]
\[
\gamma^{(5)} = -\frac{2\theta D}{\Delta_{21}} - \frac{D^2 \alpha^{(1)}_2}{\Delta_{21}^2},
\]
\[
\gamma^{(7)} = -\frac{1}{\Delta_{21}^2} \left( 2\theta D [M_1 - M_2] + 2W_2 [M_0 D + \theta \zeta^{(1)}] - \alpha^{(1)}_1 \theta \eta + \alpha^{(1)}_2 \theta^2 + \alpha^{(3)} D^2 \right),
\]
\[
\mathcal{N} = -\frac{\theta \eta}{\Delta_{21}} + \frac{D}{\Delta_{21}^2} \left( \zeta^{(1)} D [W_1 + W_2] + \alpha^{(1)}_1 \theta - \alpha^{(1)}_2 \eta \right),
\]
\[
\zeta = \frac{1}{\Delta_{21}^2} \left( D^2 + 2\eta \zeta^{(1)} [W_2 - \alpha^{(1)}_1 \eta \theta] \right), \Delta_{21} = \epsilon_2 - \epsilon_1.

A. Nadjafov, and N. Mamedov, Unoccupied topological gap in the topological insulator Bi$_2$Se$_3$ (the $C_{4v}$ crystal symmetry) [12]. The four-fold symmetric field $B(3) = k^2(\sin 3\varphi_k, \cos 3\varphi_k, 0)$ was proved to cause a triple winding of the surface-state spin. Here, the non-orthogonality is $\sin \delta = \pm \hat{z} k^3 \sin 4\varphi_k|B|$, with the in-plane field $|B| = (\hat{\alpha}^2 + \hat{\gamma}^2 k^2)k^2 - 2\hat{z}\tilde{z}k^4 \cos 4\varphi_k$ in the notation of Ref. [12]. The cubic in-plane field contributes to the four-fold warping of the CECs through the scalar product $B(3) \cdot \hat{B}^{(1)}$, as in the present study. Note that an additional contribution to both the locking angle and the warping may also come from the four-fold symmetric field $B(5) = k^2(\sin 5\varphi_k, -\cos 5\varphi_k, 0)$.
