Abstract—Amino acid salt can be a promising alternative as the promoter for increasing the absorption kinetics rate of MDEA toward CO₂. In this study, the absorption kinetics of carbon dioxide (CO₂) into an aqueous 40 wt% equivalent Methyldiethanolamine (MDEA) solution promoted by 1 and 5 wt% of mixed amino acid salt, potassium salt of l-arginine (Arg) and l-glutamic acid (Glu), was performed using a wetted wall column at temperatures from 303.15 to 323.15 K. Effect of various mixture ratios of those promoters on the reaction rate parameters and its physicochemical properties was investigated based on the fast pseudo-first-order regime. The reaction between CO₂ and amino acid was described with the zwitterionic mechanism. Aqueous MDEA without promoter was set as the control. The result revealed that the mixed promoter has affected to increase CO₂ absorption rate into the aqueous MDEA solution compared with the control and using the single promoter due to the interaction between Arg and Glu. In addition, the overall reaction rate constant, kω, significantly increased with the increase of mixed promoter concentration and temperature under the investigated range. The aqueous MDEA solution promoted by 5% of mixed Arg and Glu in 1:1 ratio was obtained as the best CO₂ absorbent.

Keywords—CO₂ absorption kinetics; l-arginine; l-glutamic acid; MDEA; mixed promoter; wetted wall column.

I. INTRODUCTION

Nowadays, biogas as renewable and sustainable energy receives significant attention due to its potential utilization innovations which can be used in the various commercially feasible methods such as electricity generation; transport fuel; and multigeneration of heat, steam, electricity, and cooling in industry. Moreover, biogas can be utilized for energy storage applications; to stabilize intermittently operated wind and solar renewable energy systems or in cooking and lighting applications in rural districts [1]. However, the presence of CO₂ as major gas products in biogas, besides methane (CH₄), has given disadvantages because of its corrosive nature that can destroy pipelines and equipment. CO₂ also reduces the heating value of biogas due to its role as an inert gas in terms of combustion [2], [3]. The biogas which contains 60 vol% of CH₄ and 40 vol% of CO₂ has a low heat value (LHV) of 17,717 (kJ kg⁻¹) or about 2.9 times lower than 100 vol% CH₄ gas which has the LHV of 50,200 (kJ kg⁻¹) [4]. Therefore, CO₂-capture technologies are so essential prior to that biogas utilization.

One of that technologies is based on the chemical absorption process which has widely employed due to its higher capture efficiencies even at low concentrations of CO₂, higher selectivity and lower cost than the other processes [5]. In chemical absorption, a solvent with high CO₂ loading capacity and low regeneration energy is an interesting topic to be developed recently. In this case, MDEA was reported has a higher CO₂ loading capacity compared to commonly used alkanolamine such as monoethanolamine (MEA) and diethanolamine (DEA). In addition, it is not corrosive to carbon steel and has lower energy requirements for regeneration, lower solvent degradation rate compared to MEA and DEA, and high selectivity toward H₂S as the trace element in raw biogas [6], [7]. Unfortunately, its reaction rate to CO₂ is lower than MEA and DEA. Therefore, the suitable alternative promoters to improve its reaction rate are highly needed.

Amino acid salts have been investigated to obtain a promising alternative promoter due to their oxidative stability and negligible volatility [8]. Furthermore, it has favorable biodegradation properties which make it environmentally friendly [9]. Many kinds of amino acid salts such as potassium salt of l-arginine, l-glutamic acid, l-proline, l-ornithine, methionine, β-alanine, sarcosine, glycine, lysinate, taurine, and 6-Aminohexanoic acid have been used as a single promoter in the aqueous amine and alkanolamine solution to absorb CO₂ [9]–[11]. To the best of our
knowledge, one of which was never used with others as a mixed promoter in MDEA solution.

In this study, the potassium salt of Arg and Glu were selected as a mixed promoter in aqueous 40 wt% equivalent MDEA solution to capture CO\textsubscript{2} under the biogas circumstance. Arg is an expensive amino acid which has a higher CO\textsubscript{2} absorption kinetics rate and apparent rate constant than Glu. In contrast, Glu has a relatively low pKa value and high overall rate constant which is potentially good for minimizing energy requirements during the regeneration or desorption process. Therefore, their combination was hypothesized to give a better CO\textsubscript{2} absorption process at a lower cost. Therefore, this study aims to investigate the effect of utilization of mixed Arg and Glu as promoter at various ratio and temperature on the kinetics of CO\textsubscript{2} absorption into the MDEA solution and to determine the reaction rate constant of each promoter in aqueous MDEA/Arg/Glu solution system to evaluate its performance as a mixed promoter.

II. MATERIALS AND METHOD

A. Chemical

L-arginine (≥99% purity) and l-glutamic acid (≥99% purity) were purchased from Sigma Aldrich. MDEA was received with a given purity of ≥98%. A mixed gas of CO\textsubscript{2} and N\textsubscript{2} have been used with the fixed volumetric concentration ratio of CO\textsubscript{2} to N\textsubscript{2} at 40:60. The high concentration of CO\textsubscript{2} in the gas feed was adapted to typical biogas characteristic. Nitrogen has been used to substitute methane gas, which is acceptable due to the same characteristic as inert gas toward the absorbent solution. Potassium hydroxide (KOH), sodium hydroxide, hydrogen chloride, barium chloride, sodium borate, oxalic acid, and other chemicals used for titration analysis were purchased from Merck.

B. Experimental section

The experiment was conducted at 303.15, 313.15, 323.15, and 333.15 K using a wetted wall column (WWC) under modified design from the previous work of [12]. WWC’s dimension and other supporting apparatus in the present study are presented in Fig. 1. The absorbent solution was made by mixing an aqueous 40 wt% equivalent MDEA solution supplemented by 1 or 5 wt% of mixed Arg and Glu with the ratio of 1:0, 0:1, 1:1 and 1:2. Aqueous MDEA solution without promoter was set as a control. Arg and Glu have been deprotonated using equimolar of KOH, forming the amino acid salt solution which is more reactive toward CO\textsubscript{2}. The temperature of the absorbent solution was adjusted using a hot water bath. After reaching out the operating temperature, it was pumped to overflow tank and prepared to enter the WWC. Mixed gas from the mixed gas tank was firstly saturated with water vapor in a saturator tank to easily maintain the balance CO\textsubscript{2} mass during CO\textsubscript{2} absorption. That absorbent solution and mixed gas were set in 200 mL min\textsuperscript{-1} and 6 L min\textsuperscript{-1}, respectively using mass flow controller before introducing to the WWC. The process phenomenon in WWC has been explained in detail by [13]. For short, it can allow counter-current contact between a falling thin liquid film and a flowing gas stream with a measurable surface area of the column for accurate measurements of CO\textsubscript{2} flux into the solution.

C. Analysis

To determine the absorption rate of CO\textsubscript{2} (q) into the absorbent solution, CO\textsubscript{2} concentration in liquid samples before and after contacting process in the WWC has been analyzed and calculated by equation (1). The liquid sample was drawn from the WWC outlet when the system reached steady state condition. The concentration of free dissolved CO\textsubscript{2} and RNHCOO\textsuperscript{-} in the liquid sample was analyzed using the method as described by [14] which allowed converting those species to HCO\textsubscript{3}\textsuperscript{-}, then to CO\textsubscript{3}\textsuperscript{2-} using excess NaOH. An excess amount of 0.5M barium chloride (BaCl\textsubscript{2}) solution was added into the sample to precipitate all carbonate in form of BaCO\textsubscript{3}. Then, that precipitation was filtered using vacuum filtration through a 0.45 Millipore filter and dissolved with a known volume of 0.1M HCl in excess. The remaining excess amount of HCl was calculated using titration with NaOH in the presence of methyl orange as an endpoint indicator.

\[
q = \frac{v ([CO_2]_{\text{final}} - [CO_2]_{\text{initial}})}{t}
\]  

(1)

The pH of the liquid sample was determined by pH-meter from Laqua (HORIBA Advanced Techno Co. Ltd). Its density and viscosity were measured using pycnometer and Ostwald viscometer, respectively, to estimate the liquid-film thickness and the contact time in the WWC [15].

![Fig. 1 WWC dimension and its other supporting apparatus.](image-url)
D. Reaction Kinetic Measurements

MDEA is a tertiary amine group while $l$-arginine and $l$-glutamic acid are amino acids which more reactive toward CO$_2$. The molecular structure of MDEA, Arg, and Glu are presented in Table I.

| Name of species | Molecular Structure | pKa | Ref. |
|-----------------|---------------------|-----|------|
| MDEA            | ![MDEA structure](image) | 8.62 | [16] |
| $l$-Arginine    | ![l-Arginine structure](image) | 2.01(-COOH) 9.04 (-NH$_3^+$) 13.8 ± 0.1 (R group) | [13] |
| $l$-Glutamic acid | ![l-Glutamic acid structure](image) | 9.98 | [11] |

If these amino acid are dissolved in water, the amino group will be completely protonated. The ionic equilibrium of the amino acids is shown in equation (2) [11].

$$\text{HO}_2\text{CRNH}_3^+ \leftrightarrow \text{H}^+ + \text{O}_2\text{CRNH}_3^+ \leftrightarrow 2\text{H}^+ + \text{O}_2\text{CRNH}_2 \quad (2)$$

In aqueous solutions, the reaction of CO$_2$ with amino acid, Arg and Glu (denoted by RH$_3$), is similar with primary and secondary alkanolamines because they have the same functional groups [11], as written below:

$$\text{CO}_2 + 2\text{RNH}_2 \leftrightarrow \text{RNH}_3^+ + \text{RNHCOO}^- \quad (3)$$

where $k_{\text{RNH}_2}$ is $k_{\text{promoter}}$ as described in the equation (44).

The direct reaction between CO$_2$ with Arg and Glu results in the zwitterion intermediate as shown in equation (4). Then, the zwitterion is deprotonated by the bases (B) in the solution such as OH$^-$, guanidinium group in the side chain of arginine (see Table I), H$_2$O, and MDEA.

$$\text{CO}_2 + \text{RNH}_2 \leftrightarrow \text{RNH}_3^+ + \text{COO}^- \quad (4)$$

$$\text{RNH}_3^+ + \text{COO}^- + \text{B} \leftrightarrow \text{RNHCOO}^- + \text{BH}^+ \quad (5)$$

Furthermore, a reaction of carbamate reversion could be occurred during the process, to form bicarbonate. Its overall reaction is written in equation (8) which is not possibly resulted by direct reaction with water. It is suggested that reaction has resulted from the competing mechanisms of carbamate formation and the bicarbonate formation. Reference [18] described that the sum of the reverse carbamate formation and the bicarbonate formation in equation (6) and (7), respectively, gives the explanation for that carbamate reversion.

$$\text{RNH}_3^+ + \text{RNHCOO}^- \leftrightarrow \text{CO}_2 + 2\text{RNH}_2 \quad (6)$$

$$\text{CO}_2 + \text{H}_2\text{O} + \text{RNH}_2 \leftrightarrow \text{RNH}_3^+ + \text{HCO}_3^- \quad (7)$$

$$\text{RNHCOO}^- + \text{H}_2\text{O} \leftrightarrow \text{RNH}_3^+ + \text{HCO}_3^- \quad (8)$$

CO$_2$ gas was absorbed into aqueous MDEA solution and the stoichiometry and equilibrium reaction are described as the following equations;

$$\text{CO}_2 + \text{H}_2\text{O} + \text{MDEA} \longleftrightarrow \text{MDEAH}^+ + \text{HCO}_3^- \quad (9)$$

$$\text{H}_2\text{O} \longleftrightarrow \text{H}^+ + \text{OH}^- \quad (10)$$

$$\text{CO}_2 + \text{H}_2\text{O} \leftrightarrow \text{H}^+ + \text{HCO}_3^- \quad (11)$$

$$\text{HCO}_3^- \leftrightarrow \text{H}^+ + \text{CO}_3^{2-} \quad (12)$$

$$\text{MDEA} + \text{H}^+ \rightarrow \text{MDEAH}^* \quad (13)$$

Where,

$$K_{\text{MDEA}} = \frac{c_{\text{MDEAH}^+} \cdot c_{\text{HCO}_3^-}}{c_{\text{CO}_2}c_{\text{MDEA}}} \quad (14)$$

$$K_w = c_{\text{H}^+}c_{\text{OH}^-} \quad (15)$$

$$K_1 = \frac{c_{\text{HCO}_3^-} \cdot c_{\text{H}^+}}{c_{\text{CO}_2}} \quad (16)$$

$$K_2 = \frac{c_{\text{CO}_3^{2-}} \cdot c_{\text{H}^+}}{c_{\text{HCO}_3^-}} \quad (17)$$

$$K_3 = \frac{c_{\text{MDEAH}^+} \cdot c_{\text{H}^+}}{c_{\text{MDEA}} \cdot c_{\text{H}^+}} \quad (18)$$

In the present study, there were several assumptions to measure the kinetic reaction value.

1. The concentration of formed bicarbonate that became carbonate was very small. Hence its concentration was equal to MDEAH$^+$ concentration.

2. Promoter concentration is constant.

By rearranging the equations (14)-(18), $c_{\text{OH}^-}$ and $c_{\text{CO}_2,e}$ could be determined as the equation (19) and (20), respectively:

$$c_{\text{OH}^-} = \frac{K_w c_{\text{CO}_3^{2-}}}{K_2 c_{\text{H}^+}} \quad (19)$$

$$c_{\text{CO}_2,e} = \frac{k_3 K_2 (c_{\text{HCO}_3^-})^2}{k_1 K_{\text{MDEA}} c_{\text{CO}_3^{2-}}} \quad (20)$$

Then $K_w$ was determined as below [19]:

$$K_w = \exp(140.932 - \frac{13445.9}{T} - 22.4773) \quad (21)$$

$K_1$ and $K_2$ were obtained from equation (22) and (23), respectively [20]. $K_3$ was determined by equation (24), as described by [10, 11]

$$K_1 = \exp(235.482 - \frac{12092.1}{T} - 36.7816 \ln T) \quad (22)$$

$$K_2 = \exp(220.067 - \frac{12431.7}{T} - 35.4819 \ln T) \quad (23)$$

$$K_3 = \frac{1}{10^{(-1.43017\pm0.01847)}} \quad (24)$$

$$K_{\text{MDEA}} = K_1K_3 \quad (25)$$

The following reaction mechanisms have also occurred in the solution:

$$\text{CO}_2 + \text{H}_2\text{O} \rightarrow \text{HCO}_3^- + \text{H}^+ \quad (26)$$

$$\text{CO}_2 + \text{OH}^- \rightarrow \text{HCO}_3^- \quad (27)$$

For Solution pH > 8, the reaction (26) could be ignored, and the reaction (27) is predominant and a limiting reaction rate.
The forward reaction is pseudo first order, and the reverse reaction rate is constant. Hence, its reaction rate is

\[ r_{CO_2-OH^-} = k_{OH^-}C_{OH^-}(C_{CO_2} - C_{CO_2,e}) \] (28)

which \( k_{OH^-} \) have been explained by [22] as:

\[ \log_{10}k_{OH^-} = 13.635 - \frac{2895}{T(K)} \] (29)

Diffusivity coefficient in the gas and liquid phase was defined by the following equation (30) [23] and (31), respectively:

\[ D_{AG} = \left( \frac{T}{298.15K} \right)^{1.75} \times 0.167x \times 10^{-4} \] (30)

\[ D_{AL/BL} = 1,173 \times 10^{-16} \sqrt{\left(qM_g \right) \frac{T}{\mu_BV_A^2}} \] (31)

Mass transfer coefficient at the gas side (\( k_g \)) was measured by equation (32) [24]:

\[ k_g = \frac{Sh DG}{RT \, h} \] (32)

where,

\[ Sc = \frac{\mu_g}{\rho_g \, D_{AG}} \] (33)

\[ V = \frac{4 \times q_G}{\pi \times d^2} \] (34)

\[ Re = \frac{\mu_g \, v \, h}{\mu_g} \] (35)

\[ Sh = 1.075 \left( Re \, Sc \frac{d}{h} \right)^{0.85} \] (36)

Solubility data were obtained from Henry’s equation below [25]:

\[ \log \left( \frac{He}{He^0} \right) = h_1 I_1 + h_2 I_2 \] (37)

\[ H_{e}^{0} = H_{e}^{0} 298 \exp \left( \frac{-d \ln kh}{d(T)} \right) \times \left( \frac{1}{T} - \frac{1}{298} \right) \] (38)

where \( \frac{-d \ln kh}{d(T)} \) for CO2 was 2400 K [26].

The concentration of carbon dioxide in the solution interface, \( C_{CO_2,i} \), was determined by the trial of \( k_{ov} \) using equation (39):

\[ C_{CO_2,i} = \frac{k_gP_A + C_{CO_2}v \sqrt{D_{AL}k_{ov}}}{k_gH_e + \sqrt{D_{AL}k_{ov}}} \] (39)

After determining the value of \( C_{CO_2,i} \), \( k_{ov} \) has been determined using the following equations [22]:

\[ \varphi = \left( \frac{q_x k_g x h_e}{k_g P_A + C_{Ac} k_g H_e - q} \right) \] (40)

\[ \varphi = \sqrt{D_{AL}k_{ov}} \] (41)

From previous research by [27], \( k_{MDEA} \) was determined by equation (9) where \( k_{MDEA} = 4.01 \times 10^9 \exp (-5400/T) \). The overall reaction \( r_{ov} \) could be defined as the equation (42), as reported by [13]:

\[ r_{ov} = k_{ov}(C_{CO_2} - C_{CO_2,e}) \] (42)

Where \( k_{ov} \) is the constants of reaction rate for overall pseudo first order:

\[ k_{ov} = k_{OH^-}C_{OH^-} + k_{app}C_{ promoter} + k_{MDEA}C_{MDEA} \] (43)

\[ k_{app}C_{ promoter} = k_{ov} - k_{OH^-}C_{OH^-} - k_{MDEA}C_{MDEA} \] (44)

where,

\[ k_{app}C_{ promoter} = k_{Arg}C_{Arg} + k_{Glu}C_{Glu} \] (45)

The individual reaction rate constants of \( k_{Arg} \) and \( k_{Glu} \) were expressed by the Arrhenius equation:

\[ Y = B + m X_1 \] (46)

where,

\[ k_{ promoter} = A_{ promoter} \, e^{-E_{A}/R} \] (47)

Equation (46) was modified to be equation (48):

\[ \ln k_{promoter} = \ln A_{ promoter} \, e^{-E_{A}/T} \] (48)

thus,

\[ Y = \ln k_{promoter} ; B = \ln A_{promoter} ; m = E \, and \, X_1 = 1 \] (49)

III. RESULTS AND DISCUSSION

A. Effect of the mixed promoter on density, viscosity, and CO2 absorption rate

Density, viscosity, and CO2 absorption rate have been investigated for aqueous 40 wt% equivalent MDEA solution promoted by 1 wt% and 5 wt% of mixed Arg and Glu with different ratios at the temperature of 303.15, 313.15, and 323.15 K, as listed in Table II. pH of the sample during the steady-state condition was in the range of 10.6-11.03.

The results revealed that the promoter concentration and temperature certainly influence the density, viscosity, and CO2 absorption rate. At the same mixed promoter’s concentration and ratio, density and viscosity decreased as temperature increase. In contrast, CO2 absorption rates increased as temperature and promoter concentration increase (see Fig. 2). That was occurred due to the increase of molecular kinetic energy that took effects on the acceleration of reacted molecular substances [28], and therefore caused the faster absorption reaction of CO2 into the absorbent solution.

In addition, it was caused by the presence of amine group in the chain of Arg and Glu which allow to react quickly with CO2 to form zwitterions and transfer protons to MDEA [29]. Hence, the absorption rate of CO2 was increased greatly, compared with the aqueous MDEA (only) solution. The zwitterionic mechanism was presented in equation (4). The contact time \( (t_c) \), has been derived from the WWC hydrodynamics, Equation (50) [22]. It showed the time needed to contact between the gas and absorbent solution in the WWC. The measured \( t_c \) are presented in Table II.

\[ t_c = \frac{h}{v_s} = \frac{2h}{3} \left( \frac{3n}{d_p} \right)^{1/3} \left( \frac{d_h}{v} \right)^{2/3} \] (50)
The CO₂ absorption rate was calculated using equation (1) and shown in Fig. 2 which demonstrates the obvious effect on absorption behavior. The addition 1 wt% of single promoter presented in Arg:Glu (1:0 ratio) has a better CO₂ absorption rate than Arg:Glu (0:1 ratio) along with the rise of temperature. Arg shows a high absorption rate because it has the primary amino group and a guanidinium group in its side chain, causing a pKa value higher than Glu. The basicity of an amine (pKa) can affect the CO₂ reaction rate of the amine to form a carbamate, catalyzes the hydration of CO₂, and promotes the amine to accept a proton. Where the higher pKa value will lead to an increase of $k_{app}$ value and maximize the initial CO₂ absorption rates [9]. The conjugation of double bonded nitrogen and nitrogen lone pairs in the guanidinium group is able to delocalize positive charge to participate in multiple hydrogen bonds with water, which would be helpful to form the carbamate and promote the CO₂ absorption [13]. However, another study has also stated that the high pKa would probably require larger energy input in the desorption process [11]. This is a consideration for further applications of Arg. Therefore, using a cheaper promoter with a relatively low pKa such as Glu in their mixture would come as a good strategy because their CO₂ absorption rate was higher than those as a single promoter.

In this investigation, the mixture of Arg and Glu with 1:1 ratio has resulted in the highest CO₂ absorption rate in both of addition 1 wt% and 5 wt% of mixed promoter. For 1 wt% of the mixed promoter with 1:1 ratio, CO₂ absorption rate showed a satisfied performance than the addition of 1 wt% of Arg as a single promoter. However, its value was not a significant difference in CO₂ absorption at 323.15 K. In contrast with the addition 5 wt% of the mixed promoter which obtained a higher CO₂ absorption rate with the promoter ratio of 1:1 at 323.15K. The mixed promoter ratio of 1:1 has given close CO₂ absorption rate with Arg as a single promoter, which means that Arg substitution by Glu has given a saving of cost. In this experiment, the CO₂ absorption rate for aqueous MDEA without promoter was obtained $0.6159 \times 10^{-7}$ kmol s$^{-1}$ at 313.15K. In the same temperature, the addition of 1 and 5 wt% of mixed promoter with 1:1 ratio has been increasing the CO₂ absorption rate to $1.404 \times 10^{-7}$ kmol s$^{-1}$ (~2.3 times higher) and $2.0622 \times 10^{-7}$ kmol s$^{-1}$ (3.35 times higher), respectively than 40% equivalent aqueous MDEA without promoter. This result was in accordance with the experiment proven by [30]. Amino acid has the same function with a

However, the CO$_2$ absorption rate sharply decreased at the temperature of 333.15 K. This phenomena was also found in the study of [30]. They reported that when the lean amine temperature reaches about 330.15 to 333.15 K, the solubility of CO$_2$ in the amine solution will decrease and usually become the overriding factor, and the net CO$_2$ pickup will begin to decrease. In that condition, the solubility will take over in the determination of absorption rate, not reaction kinetic anymore. Moreover, that was probably caused by MDEA degradation which can be occurred at that temperature range.

B. Fast Pseudo-first Order Evaluation

The reaction of CO$_2$ absorption into MDEA solution with a mixture of Arg/Glu promoter was investigated based on the fast pseudo-first order reaction regime. The regime must be satisfied with this condition, $3 < H_a$ (Hatta number) $< 1/2 E_i$, where the Hatta number was calculated by the following equation:

$$H_a = \frac{D_{CO_2} r_{ov}}{k_L}$$ (51)

Where $k_L$ has been determined using equations below:

$$k_L = \sqrt{\frac{4 x p_{AB} V_{max}}{\pi n}}$$ (52)

$$V_{max} = \frac{\rho g \delta}{2 \pi}$$ (53)

$$\delta = \left( \frac{3 \mu d}{\rho g \pi D} \right)^{1/3}$$ (54)

$E_i$ is an infinite enhancement factor. It is dimensionless and formulated as follow:

$$E_i = \frac{D_{AK}}{D_{BL}} + \frac{C_{DCO_2}}{\epsilon E_{CO_2}} \sqrt{\frac{D_{BL}}{D_{AK}}}$$ (55)

All Hatta numbers of the absorbent have satisfied the required condition of fast pseudo-first order reaction regime (see Table III), which those numbers have more than 3 and much less than $1/2 E$.

C. Kinetic Data

In the previous chapter, a higher CO$_2$ absorption rate was obtained in 40 wt% equivalent MDEA with addition 5 wt% of the promoter. The value of $r_{ov}$, $k_{ov}$, and $k_{app}$ for this promoter concentration were calculated using equation (42), (43), and (44), respectively at 303.15, 313.15, and 323.15 K. The value of $r_{ov}$ and $k_{app}$ are listed in Table IV. While the overall absorption kinetics constant ($k_{ov}$) is displayed in Fig. 3. It reveals that the highest $r_{ov}$, $k_{ov}$, and $k_{app}$ value were obtained from the ratio 1:1 which this composition could be used as recommended consideration for further applications.

TABLE IV

| Properties | T (K) | Arg:Glu ratio for 5 wt% |
|------------|------|------------------------|
|            |      | 1:0 | 0:1 | 1:1 | 1:2 |
| $r_{ov}$    | 303.15 | 753 | 669 | 724 | 644 |
|            | 313.15 | 2474 | 1357 | 1670 | 2234 |
|            | 323.15 | 4162 | 3043 | 9331 | 3720 |
| $k_{app}$ (s$^{-1}$) | 303.15 | 15610 | 15390 | 19926 | 15739 |
|            | 313.15 | 39422 | 26372 | 36964 | 40485 |
|            | 323.15 | 59640 | 49410 | 139985 | 60305 |

Fig. 3 $r_{ov}$ values in 40 wt% equivalent MDEA with 5 wt% of the mixed promoter at the different ratio as a function of temperature.
The value of reaction rate constant of Arg and Glu as a mixed promoter in CO$_2$ absorption can be evaluated from measured $k_{\text{app}}$ at all variables of promoter concentration and mixture ratio under the investigated temperature, as shown in the equation (45). First, $k_{\text{Arg}}$ and $k_{\text{Glu}}$ in the absorbent solution and the same temperature was calculated using multiple linear regression which evaluate the effect of one or some variables to other variables, as presented in equation (56) and (57). Then, the predicted $k_{\text{app}}$ ($k_{\text{app}}'$) can be formulated as equation (58) and compared with measured $k_{\text{app}}$ to find out the calculation error.

$$
\sum \hat{k}_{\text{app}} C_{\text{Arg}} = k_{\text{Arg}} \sum C_{\text{Arg}}^2 + k_{\text{Glu}} \sum C_{\text{Glu}} C_{\text{Arg}} \quad (56)
$$

$$
\sum \hat{k}_{\text{app}} C_{\text{Glu}} = k_{\text{Arg}} \sum C_{\text{Arg}} C_{\text{Glu}} + k_{\text{Glu}} \sum C_{\text{Glu}}^2 \quad (57)
$$

$$
k_{\text{app}}' = k_{\text{Arg}} C_{\text{Arg}} + k_{\text{Glu}} C_{\text{Glu}} \quad (58)
$$

To determine the value of reaction rate constant of Arg and Glu as a single promoter ($k_{\text{Arg}}'$ or $k_{\text{Glu}}'$) in the absorbent solution, the general linear model was used with the variable data of 1 and 5 wt% from the ratio 1:0 for Arg and 0:1 for Glu.

$$
k_{\text{promoter}}' = \frac{\sum C_{\text{promoter}} k_{\text{app}}}{\sum C_{\text{promoter}}} \quad (59)
$$

$$
k_{\text{app}}' = k_{\text{promoter}}' C_{\text{promoter}} \quad (60)
$$

Finally, the $k$ value of each promoter either as a mixed promoter or single promoter has been obtained.

In this study, $k_{\text{promoter}}$ as a function of temperature over the investigated range were correlated using Arrhenius equation as shown in Fig. 4 with $R^2$ value for $k_{\text{Arg}}$, $k_{\text{Glu}}$, $k_{\text{Arg}}'$, and $k_{\text{Glu}}'$ are 0.983, 0.997, 0.999, and 0.996, respectively. The results are listed in Table V and Fig. 5.

**TABLE V**

**REACTION RATE CONSTANT OF THE SPECIES FROM THIS STUDY AND OTHER REFERENCES**

| Name of Species (solution system) | $k$ ($\text{m}^3 \text{kmol}^{-1} \text{s}^{-1}$) | References |
|----------------------------------|---------------------------------|------------|
| MDEA (MDEA/MEA solution)         | $2.58 \times 10^8 \exp(-3736.5/T)$ | [31]       |
| MDEA (MDEA solution)             | $1.146 \times 10^{16} \exp(-9567.05/T)$ | This study |
| Arg (K$_2$CO$_3$/Arg solution)   | $2.58 \times 10^8 \exp(-8645/T)$ | [13]       |
| Arg (MDEA/Arg/Glu solution)      | $2.041 \times 10^{10} \exp(-7396/T)$ | This study |
| Glu (MDEA/Arg/Glu solution)      | $6.48 \times 10^8 \exp(-6378.3/T)$ | This study |
| Arg' (MDEA-Arg solution)         | $2.22 \times 10^8 \exp(-6725.7/T)$ | This study |
| Glu' (MDEA-Glu solution)         | $8.10 \times 10^8 \exp(-5774.4/T)$ | This study |

Fig. 5 shows $k_{\text{Arg}}$ in the aqueous MDEA/Arg/Glu solution system has the highest reaction rate constant in CO$_2$ absorption than the other solution systems. It also exhibits that Arg and Glu as a mixed promoter have a higher reaction rate constant of CO$_2$ absorption compared to theirs as a single promoter.

**Fig. 4** Arrhenius plot of $k_{\text{Arg}}$, $k_{\text{Glu}}$, $k_{\text{Arg}}'$, and $k_{\text{Glu}}'$ for 40% equivalent MDEA promoted by a mixture and single promoter.

**Fig. 5** Plot reaction rate constant of CO$_2$ absorption ($k$) as a function of temperature.

**Fig. 6** Correlation between the temperature and $k$ value of MDEA and other promoters resulted from this study and the literature.
K$_2$CO$_3$/Arg solution system, investigated by [13], but still lower compared to k$_{p2}$ in MDEA/Piperazine (PZ) system, investigated by [32]. In spite of that fact, Arg was environmentally friendly and less toxic than PZ [13]. Therefore, it can be considered as a good candidate promoter.

IV. CONCLUSION

The overall absorption rate constant, k$_{ov}$, significantly increased with the increase of mixed promoter concentration (1 to 5 wt%) and temperatures from 303.15 to 323.15 K. The absorbent solution with 5 wt% mixed promoter with mixture ratio of 1:1 has given the highest CO$_2$ absorption rate and resulted in a higher reaction rate constant than Arg as a single promoter at the same concentration in 40% of aqueous MDEA solution. The results exhibited that mixed promoter could significantly increase the kinetics of CO$_2$ absorption compared with using a single promoter that was probably caused by the presence of the interaction between Arg and Glu in the aqueous MDEA solution. The reaction rate constant of MDEA, Arg, and Glu during CO$_2$ absorption into aqueous 40% equivalent MDEA promoted by mixed amino acid salt of Arg and Glu was described as the following equation:

\[ k_{MDEA} = 1.146 \times 10^{16} \exp \left( -9567.053/T \right); \]
\[ k_{Arg} = 2.041 \times 10^{15} \exp \left( -7396/T \right); \]
\[ k_{Glu} = 6.48 \times 10^{15} \exp \left( -6378.3/T \right). \]

ACKNOWLEDGMENT

The authors would like to thank LPPM ITS and all members of Biochemical Technology Laboratory and Heat and Mass Transport Laboratory, Department of Chemical Engineering for the help and support. This research was founded by PMDSU scholarship program from The Ministry of Research, Technology, and Higher Education of the Republic of Indonesia [grant number 482/PKS/ITS/2017, 2017].
