A unified proof of the Howe–Moore property

Corina Ciobotaru

January 17, 2014

Abstract

We provide a unified proof of all known examples of locally compact groups that enjoy the Howe–Moore property, namely, the vanishing at infinity of all matrix coefficients of the group’s unitary representations that are without non-zero invariant vectors. These examples are: connected, non-compact, simple real Lie groups with finite center, isotropic simple algebraic groups over non-Archimedean local fields and closed, topologically simple subgroups of Aut(T) that act 2-transitively on the boundary ∂T, where T is a bi-regular tree with valence ≥ 3 at every vertex.

1 Introduction

For a locally compact group G, the Howe–Moore property asserts that all matrix coefficients of its unitary representations, that are without non-zero G-invariant vectors, vanish at infinity. This property was first established by Howe and Moore (see [HM79]) and Zimmer (see [Zim84]), around 1977, for the connected, non-compact, simple real Lie groups that are with finite center. It plays an important role in the Mostow rigidity theorem, as well as in various other rigidity results. The original proof of the Howe–Moore property uses the geometry of the semi-simple real Lie groups. Nowadays the proof is more algebraic (see for example [BM00] or [WM, Theorem 10.14] for the case of SL(2, R)).

The study of the Howe–Moore property for the totally disconnected analogs of the semi-simple real Lie groups, namely, the closed, strongly transitive subgroups of Aut(Δ), where Δ is a locally finite thick Euclidean building, was initiated by Lubotzky and Mozes (see [LM92]) in the particular case of Δ being a d-regular tree T_d, with d ≥ 3. Using the geometry of horocycles and horoballs, they prove that the index-two subgroup of Aut(T_d), which preserves the 2-coloring of the tree T_d, enjoys this property. A more general result, in the context of d-regular trees, was obtained by Burger and Mozes in [BM00]. There they show that every closed, topologically simple subgroup of Aut(T_d)

Keywords: Unitary representations, groups acting on Euclidean buildings, the Howe–Moore property.
which is 2-transitive on the boundary has the Howe–Moore property. We mention that the latter class of subgroups of $\text{Aut}(T_d)$ contains also non-linear examples.

In a more general setting, for simple non-compact $p$-adic Lie groups a proof of the Howe–Moore property is given in [CdCL+11]. Although, as it was mentioned to us by Alain Valette, a proof of the Howe–Moore property for isotropic simple algebraic groups over non-Archimedean local fields already appears in the original paper of Howe and Moore (see [HM79, Theorem 5.1]).

Regarding all the examples presented above, this article proposes to give a unified proof of the Howe–Moore property: for connected, non-compact, simple real Lie groups, with finite center, and for their totally disconnected analogs, namely, for isotropic simple algebraic groups over non-Archimedean local fields (see Definition 4.19) and for closed, topologically simple subgroups of $\text{Aut}(T)$ that act 2-transitively on the boundary $\partial T$, where $T$ is a bi-regular tree with valence $\geq 3$ at every vertex.

**Theorem 1.1.** (See Theorem 4.16 and Section 4.1) Let $G$ be a connected, non-compact, simple real Lie groups, with finite center, or an isotropic simple algebraic group over a non-Archimedean local field, or a closed, topologically simple subgroups of $\text{Aut}(T)$ that act 2-transitively on the boundary $\partial T$, where $T$ is a bi-regular tree with valence $\geq 3$ at every vertex. Then $G$ admits the Howe–Moore property.

The main ingredients of the unified proof, are:

i) the $K_1A^+K_2$ decomposition of these groups, where $K_1, K_2$ are compact subsets and $A^+$ is the ‘maximal abelian’ sub semi-group part (see Section 4);

ii) the ‘contraction’ subgroups with respect to hyperbolic elements, combined with basic facts regarding normal operators (see Sections 2.3, 2.4).

More precisely, the above mentioned ingredients are assembled to obtain the following criterion, used to verify the Howe–Moore property:

**Theorem 1.2.** Let $G$ be a second countable, locally compact group having the following properties:

i) $G$ admits a decomposition $K_1A^+K_2$, where $K_1, K_2 \subset G$ are compact subsets and $A^+$ is an abelian sub semi-group of $G$;

ii) for all sequences $\alpha = \{g_n\}_{n>0} \subset A^+$, with $g_n \to \infty$, we have $G = \langle U^+_\alpha, U^-_\alpha \rangle$.

Then $G$ has the Howe–Moore property.

The idea behind this criterion is inspired by a proof given for $\text{SL}(2, \mathbb{R})$ by Dave Witte Morris (see [WM, Theorem 10.14]).

To the best of our knowledge, there are no other known examples of locally compact or even discrete groups enjoying the Howe–Moore property, beside those covered by the unified proof provided by this article. Some necessary algebraic conditions for a locally compact group with the Howe–Moore property are described in [CdCL+11]. Those
conditions are quite elementary, but probably far from being sufficient. Even for the two classes of groups mentioned above we still do not know to what extent the Howe–Moore property relates with the $KA^+K$ decomposition and with the strong transitivity on the boundary; in this direction, only partial results have been obtained so far.

**Acknowledgements**

This article is part of the author’s PhD project conducted under the supervision of Prof. Pierre-Emmanuel Caprace. I would like to thank him for valuable conversations and support during this project. My thanks go also to Mihai Berbec and Steven Deprez for interesting discussions, in the early stage of this work, on von Neumann algebras and partial isometries, as well as providing the elegant proof of Lemma 2.13 and the Example 2.14.

**2 Preliminaries**

**2.1 Basic definitions**

In what follows all Hilbert spaces are assumed to be complex, not necessarily separable, and their inner product is denoted by $\langle \cdot, \cdot \rangle$. Let $B(H)$ be the space of all bounded linear operators $F : H \to H$.

Recall that the closed unit ball of a Hilbert space $H$ is compact with respect to the weak topology and moreover, by the Theorem of Eberlein–Šmulian, compactness is equivalent to sequential compactness. Hence, any sequence of vectors $\{v_n\}_{n \geq 0} \subset H$, with their norms being bounded above, contains a **weakly convergent** subsequence $\{v_{n_k}\}_{k \geq 0}$ in $H$. Namely, there exists a vector $v \in H$ such that for any $w \in H$ one has that $\lim_{n_k \to \infty} \langle v_{n_k}, w \rangle = \langle v, w \rangle$.

In the same spirit, if $H$ is a separable Hilbert space, it is well-known that the closed unit ball in $B(H)$ is compact and metrizable with respect to the weak operator topology. Thus, any sequence of operators $\{F_n\}_{n \geq 0} \subset B(H)$, with their operator norms being bounded above, contains a **weakly convergent** subsequence $\{F_{n_k}\}_{k \geq 0}$ in $B(H)$. Namely, there exists $F$ in $B(H)$ such that for all $v, w \in H$ one has that $\lim_{n_k \to \infty} \langle F_{n_k}v, w \rangle = \langle Fv, w \rangle$.

**Definition 2.1.** Let $H$ be a Hilbert space. We say that $E \in B(H)$ is **normal** if $E^*E = EE^*$. It is well-known that this is equivalent to $\langle EE^*v, v \rangle = \langle E^*Ev, v \rangle$, for every $v \in H$. Moreover, $U \in B(H)$ is called **unitary** if $UU^* = U^*U = I$ or, equivalently, if $\langle U\xi, U\eta \rangle = \langle \xi, \eta \rangle$ for all $\xi, \eta \in H$ and $U$ is onto. We denote by $U(H)$ the group of all unitary operators of $H$.

**Definition 2.2.** A **unitary representation** of a topological group $G$ into a Hilbert space $H$ is a group homomorphism $\pi : G \to U(H)$, which is moreover strongly continuous: the map $g \in G \mapsto \pi(g)v \in H$ is continuous for every $v \in H$. Instead of $\pi : G \to U(H)$ we often write $\langle \pi, H \rangle$ for a unitary representation of $G$. 

3
Furthermore, any two vectors \( v, w \in \mathcal{H} \) define a continuous function \( c_{v,w} : G \to \mathbb{C} \), given by \( c_{v,w}(g) := \langle \pi(g)v, w \rangle \) and we call it the associated \((v,w)\)-matrix coefficient. Moreover, we say that \( c_{v,w} \) is \( C_0 \) if for every \( \epsilon > 0 \), the subset \( \{ g \in G : |c_{v,w}(g)| \geq \epsilon \} \) is compact in \( G \).

**Remark 2.3.** (See [BdlHV08, Proposition C.4.9]) We mention that for a unitary representation \((\pi, \mathcal{H})\) of a topological group \( G \), the Hilbert space \( \mathcal{H} \) can be decomposed as a direct sum \( \mathcal{H} = \bigoplus_i \mathcal{H}_i \) of mutually orthogonal, closed and \( G \)-invariant subspaces \( \mathcal{H}_i \), such that the restriction of \( \pi \) to \( \mathcal{H}_i \) is cyclic for every \( i \) (i.e., for every \( i \) there exists a non-zero vector \( v \in \mathcal{H}_i \) such that \( \pi(G)v \) is dense in \( \mathcal{H}_i \)).

Moreover, the following lemma asserts that for ‘nice’ topological groups, only separable Hilbert spaces can be considered when working with unitary representations.

**Lemma 2.4.** Let \( G \) be a separable locally compact group. Then for every cyclic unitary representation \((\pi, \mathcal{H})\) of \( G \), the corresponding Hilbert space \( \mathcal{H} \) is separable. In particular, all irreducible unitary representations of \( G \) are over separable Hilbert spaces.

**Proof.** Let \((\pi, \mathcal{H})\) be a cyclic unitary representation of \( G \) and denote by \( v \) a cyclic vector of it. Then, we have that \( f : G \to \mathcal{H} \), defined by \( f(g) := \pi(g)v \), is a continuous function. Moreover, by the definition of a cyclic vector, we know that the linear span of \( \pi(G)v \) is dense in \( \mathcal{H} \).

As \( G \) is separable, let \( Q \) be a countable dense subset of it. Thus \( f(Q) \) is dense in \( \pi(G)v \) and therefore the linear span of \( \pi(Q)v \) is also dense in \( \mathcal{H} \). The conclusion thus follows.

**Remark 2.5.** The class of separable locally compact groups contains non-compact, simple real Lie groups with finite center and also closed, non-compact subgroups of Aut(\( \Delta \)), where \( \Delta \) is a locally finite thick Euclidean building. In particular, all non-compact, simple \( p \)-adic Lie groups are separable.

### 2.2 The Howe–Moore property

**Definition 2.6.** Let \( G \) be a locally compact group. By \( \overline{G} := G \cup \{\infty\} \) we denote the one point compactification of \( G \). We say that \( G \) has the **Howe–Moore property** if the set of all unitary representations of \( G \) is the union of the ones having non-zero \( G \)-invariant vectors and the ones for which all matrix coefficients are \( C_0 \). When a matrix coefficient is \( C_0 \), we say also that it vanishes at \( \infty \).

Throughout this article we assume that all locally compact groups are second countable; this is to simplify our notations, by using sequences instead of nets. The second reason is given by the next remark.

**Remark 2.7.** By [CdCL+11, Prop. 2.3], to prove the Howe–Moore property for a second countable, locally compact group \( G \) it is enough to verify the \( C_0 \) condition only for all irreducible, non-trivial, unitary representations of \( G \), which, by Lemma 2.4, are over separable Hilbert spaces.
Moreover, the following well-known lemma shows that matrix coefficients not vanishing at $\infty$ give rise to particular matrix coefficients with the same property.

**Lemma 2.8.** Let $G$ be a second countable, locally compact group and $(\pi, \mathcal{H})$ be a unitary representation of $G$. Suppose there exist two non-zero vectors $v, w \in \mathcal{H}$ such that the $(v, w)$-matrix coefficient does not vanish at $\infty$. Then the $(v, v)$-matrix coefficient does not vanish at $\infty$.

**Proof.** By hypothesis, there exists a sequence $\{g_n\}_{n \geq 0} \subset G$ such that $g_n \to \infty$ and $|\langle \pi(g_n)v, w \rangle| \to 0$. Thus $w$ is not orthogonal to the Hilbert subspace generated by $\pi(G)v$. Denote this Hilbert subspace by $\overline{\pi(G)v}$ and remark this is $G$-invariant.

Moreover, $\{\pi(g_n)v\}_{n \geq 0}$ being bounded in the norm of $\mathcal{H}$, there exist $v_0 \in \mathcal{H}$ and a subsequence $\{n_k\}_{k \geq 0}$ such that $\{\pi(g_{n_k})v\}_{k \geq 0}$ weakly converges to $v_0$. Thus $\lim_{n_k \to \infty} \langle \pi(g_{n_k})v, w' \rangle = \langle v_0, w' \rangle$, for every $w' \in \mathcal{H}$. From here we conclude that $v_0$ is a non-zero vector.

Furthermore, we claim that $v_0$ is a vector in $\overline{\pi(G)v}$. Indeed, suppose the converse that $v_0 = w_1 + w_2$, with $w_1 \in \pi(G)v$ and $w_2$ a non-zero vector orthogonal to $\overline{\pi(G)v}$. Taking $w' = w_2$, we obtain that $\lim_{n_k \to \infty} \langle \pi(g_{n_k})v, w_2 \rangle = 0 = \langle v_0, w_2 \rangle$, which is impossible.

The claim follows and we conclude that there exists $g \in G$ such that $\langle v_0, \pi(g)v \rangle \neq 0$. For this $g$ we obtain that $\lim_{n_k \to \infty} \langle \pi(g_{n_k})v, \pi(g)v \rangle = \langle v_0, \pi(g)v \rangle$. The conclusion follows by only remarking that $|\langle \pi(g^{-1}g_{n_k})v, v \rangle| \to 0$.

In addition, the following easy lemma asserts that compact subsets do not count for the Howe–Moore property, given a ‘polar decomposition’ of the locally compact group.

**Lemma 2.9.** Let $G$ be a second countable, locally compact group admitting a decomposition $G = K_1AK_2$, where $K_1, K_2$ are compact subset and $A$ is any subset of $G$. Let $(\pi, \mathcal{H})$ be a unitary representation of $G$. If for every sequence $\{a_n\}_{n \geq 0} \subset A$, with $\{a_n\}_{n \geq 0} \to \infty$, the corresponding matrix coefficients vanish at $\infty$, then all matrix coefficients of $G$, with respect to $(\pi, \mathcal{H})$, vanish at $\infty$.

**Proof.** Suppose there exist a sequence $\{g_n\}_{n \geq 0} \subset G$, with $g_n \to \infty$, and two non-zero vectors $v, w \in \mathcal{H}$ such that the corresponding matrix coefficient $\langle c_{v,w}(g_n) \rangle$ does not vanish at $\infty$. As $G = K_1AK_2$ one has $g_n = k_n a_n h_n$, where $k_n \in K_1$, $h_n \in K_2$ and $a_n \in A$, for every $n > 0$. We have thus $a_n \to \infty$. As $K_1, K_2$ are compact sets and by passing to a subsequence, we can assume that $\{\pi(k_n)^{-1}w\}_{n \geq 0}$ and $\{\pi(h_n)v\}_{n \geq 0}$ converge, in the norm of $\mathcal{H}$, to the vectors $w_0$, respectively $v_0$. One has:

\[
|\langle \pi(k_nh_nh_n)v, w \rangle| = |\langle \pi(a_nh_nh_n)v, \pi(k_n)^{-1}w \rangle - \langle \pi(a_nh_nh_n)v, w_0 \rangle + \langle \pi(h_n)v, \pi(a_n)^{-1}w_0 \rangle - \langle \pi(h_n)v, \pi(a_n)^{-1}w_0 \rangle + \langle \pi(a_n)v_0, w_0 \rangle|
\]

\[
\leq \|\pi(k_n)^{-1}w - w_0\| \cdot \|v\| + \|\pi(h_n)v - v_0\| \cdot \|w_0\| + |\langle \pi(a_n)v_0, w_0 \rangle|.
\]

As the first two terms tend to zero as $n \to \infty$, we have that the matrix coefficient $c_{v_0,w_0}(a_n)$ does not vanish at $\infty$. We obtain a contradiction and the conclusion follows.
Let us add here some necessary algebraic conditions for a non-compact locally compact group to admit the Howe–Moore property; however, those conditions are far from being sufficient.

**Proposition 2.10.** (See Prop. 3.2 in [CdCL+11]) Let $G$ be a non-compact locally compact group with the Howe–Moore property. Then any proper open subgroup of $G$ is compact and thus of infinite index in $G$.

### 2.3 Mautner’s phenomenon

One of the main ideas to verify the Howe–Moore property is to search for ‘big’ subgroups $H \leq G$ admitting at least one non-zero $H$-invariant vector in $\mathcal{H}$. The Mautner’s phenomenon gives us a method to construct such subgroups. First, let us introduce the following:

**Definition 2.11.** Let $G$ be a locally compact group. Let $\alpha = \{g_n\}_{n>0}$ be a sequence in $G$. This sequence $\alpha$ defines the set:

$$U^+_\alpha := \{ g \in G \mid \lim_{n \to \infty} g_n^{-1} g g_n = e \}.$$  

Notice that $U^+_\alpha$ is a subgroup of $G$. It is called the **contraction group** corresponding to $\alpha$. Because it doesn’t need to be closed in general, we denote by $N^+_\alpha$ the closed subgroup $U^+_\alpha$. In the same way, but using $g_n g g_n^{-1}$ we define $U^-_\alpha$ and $N^-_\alpha$. When $\alpha = \{a^n\}_{n>0}$, for some $a \in G$, we simply use the notations $U^\pm_a := U^\pm_\alpha$ and $N^\pm_a := N^\pm_\alpha$.

We record the following lemma, known as Mautner’s phenomenon (see [BM00, Chp. III, Thm. 1.4]):

**Lemma 2.12.** Let $G$ be a second countable, locally compact group and $(\pi, \mathcal{H})$ be a unitary representation. Let $\{g_n\}_{n>0}$ be a sequence in $G$ and take $v \in \mathcal{H}$ a non-zero vector. Suppose moreover that $\{\pi(g_n)v\}_{n>0}$ weakly converges to $v_0$.

Then $v_0$ is $N^+_\alpha$-invariant.

**Proof.** Let $w \in \mathcal{H}$ be an arbitrary vector and take $g \in U^+_\alpha$. We have:

$$| \langle \pi(g)v_0 - v_0, w \rangle | = \lim_{n \to \infty} | \langle \pi(g_n) v - \pi(g_n)v, w \rangle |$$

$$= \lim_{n \to \infty} | \langle \pi(g_n^{-1} g g_n) v - v, \pi(g_n^{-1})w \rangle |$$

$$\leq \lim_{n \to \infty} \| \pi(g_n^{-1} g g_n) - Id_\mathcal{H} \| v \cdot \| w \| = 0.$$

Since $U^+_\alpha$ is dense in $N^+_\alpha$ and $\pi$ is continuous, it follows that $N^+_\alpha$ fixes $v_0$. \hfill \Box

### 2.4 Normal operators as weak limits

This elementary lemma is a key step used in Section 3.
Lemma 2.13. Let $\mathcal{H}$ be a separable Hilbert space and consider a sequence $\{U_n\}_{n>0} \subset \mathcal{U}(\mathcal{H})$ of pairwise commuting operators.

Then there exists a subsequence $\{U_{n_k}\}_{n_k}$ which weakly converges to an operator $E \in \mathcal{B}(\mathcal{H})$. Moreover, any such weak limit is normal.

First proof. As $\{U_n\}_{n>0}$ are unitary operators, they have norm one in $\mathcal{B}(\mathcal{H})$. Hence, there is a subsequence $\{U_{n_k}\}_{n_k}$ which weakly converges to an operator $E \in \mathcal{B}(\mathcal{H})$. It remains to prove that $E$ is normal. In what follows we replace the subsequence $\{U_{n_k}\}_{n_k}$ by the sequence $\{U_n\}_{n>0}$.

As $\{U_n\}_{n>0}$ are unitary operators, one has:

$$\lim_{n \to \infty} \langle U_n v, w \rangle = \lim_{n \to \infty} \langle v, U_n^* w \rangle = \langle Ev, w \rangle,$$

for all $v, w \in \mathcal{H}$. Hence $E^*$ verifies that $\lim_{n \to \infty} \langle v, U_n^* w \rangle = \langle v, E^* w \rangle$, for all $v, w \in \mathcal{H}$.

By hypothesis, the unitary operators $\{U_n\}_{n>0}$ commute pairwise, thus $U_n$ and $U_k$ commute for all $n, k > 0$. Therefore for all $v, w \in \mathcal{H}$ one has:

$$\langle EE^* v, w \rangle = \lim_{n \to \infty} \langle U_n (E^* v), w \rangle = \lim_{n \to \infty} \langle E^* v, U_n^* w \rangle = \lim_{n \to \infty} ( \lim_{k \to \infty} \langle U_n^* U_k v, w \rangle ) = \lim_{n \to \infty} \langle U_n v, E w \rangle = \langle Ev, Ew \rangle = \langle E^* Ev, w \rangle.$$

Second proof. Another way to see this is using von Neumann algebras. More precisely, as the unitary operators $\{U_n\}_{n>0}$ commute pairwise, they generate a commutative von Neumann algebra which is closed, by definition, in the weak topology. Thus the weak limit $E$ is also contained in this von Neumann algebra. We conclude that $E$ is normal as operator.

The pairwise commutativity condition in Lemma 2.13 is essential to obtain a normal weak limit. The following is an example in that sense.

Example 2.14. Take for example the Koopman unitary representation $\pi : \text{SL}(2, \mathbb{R}) \to \mathcal{U}(L^2(\text{SL}(2, \mathbb{R})/\text{SO}(2, \mathbb{R})))$. This representation is known to be without non-zero $\text{SL}(2, \mathbb{R})$-invariant vectors and by the Howe–Moore property, all its matrix coefficients of are $\mathcal{C}_0$. Let $A$ be a diagonal matrix, which is a hyperbolic element of $\text{SL}(2, \mathbb{R})$, and take the sequence $\{\pi(A^n)\}_{n>0}$ of unitary operators, whose weak limit is zero by the Howe–Moore property.

Consider now the Hilbert space $\mathcal{H} := \mathbb{C} \bigoplus L^2(\text{SL}(2, \mathbb{R})/\text{SO}(2, \mathbb{R}))$ and define the operator $U_n := \begin{pmatrix} 0 & \pi(A^n) \\ \text{id} & 0 \end{pmatrix}$. It is easy to see that $\{U_n\}_{n>0}$ is a sequence of unitary operators of $\mathcal{H}$ which do not commute pairwise and whose weak limit is the partial isometry $E = \begin{pmatrix} 0 & 0 \\ \text{id} & 0 \end{pmatrix}$. Also the weak limit of $\{U_n^*\}_{n>0}$ is the operator $E^* = \begin{pmatrix} 0 & \text{id} \\ 0 & 0 \end{pmatrix}$. 

One can see, formally, that $EE^* = \begin{pmatrix} 0 & 0 \\ 0 & \text{id} \end{pmatrix}$ and $E^*E = \begin{pmatrix} \text{id} & 0 \\ 0 & 0 \end{pmatrix}$. The conclusion follows.

## 3 An algebraic criterion

This section proposes a criterion, given by Theorem 3.2, to verify the Howe–Moore property, over separable Hilbert spaces, for locally compact groups admitting a special decomposition. Its proof uses the idea of Dave Witte Morris (see [WM] Theorem 10.14), which relies on a more elaborate version of the Mautner’s phenomenon; for further references this idea is recorded in a separate lemma.

**Lemma 3.1.** Let $G$ be a second countable, locally compact group and $(\pi, \mathcal{H})$ be a unitary representation of $G$, without $G$-invariant vectors. Assume there exists a sequence $\alpha = \{g_n\}_{n>0}$ of pairwise commuting elements of $G$ such that $g_n \to \infty$, $G = \overline{\langle U_1^+, U_1^- \rangle}$ and $\{\pi(g_n)\}_{n>0}$ weakly converge to an operator $E \in B(\mathcal{H})$.

Then all matrix coefficients of $(\pi, \mathcal{H})$ corresponding to $\{g_n\}_{n>0}$ vanish at $\infty$.

**Proof.** Suppose there exist two non-zero vectors $v, w \in \mathcal{H}$ (considered fixed for what follows) such that $|\langle \pi(g_n)v, w \rangle| \to 0$. Because $\{\pi(g_n)\}_{n>0}$ weakly converge to an operator $E$, by Lemma 2.13 we have moreover that $E$ is normal and $E \neq 0$.

We now claim that the following important property of $E$ holds: $\pi(u_+)E\pi(u_-) = E$, for every $u_+ \in U_1^+$ and every $u_- \in U_1^-$. 

**Justification.**

Let $u_- \in U_1^-$. For every $\phi, \psi \in \mathcal{H}$ one has:

$$|\langle E\pi(u_-)\phi, \psi \rangle - \langle E\phi, \psi \rangle| = |\lim_{n \to \infty} \langle \pi(g_n u_-)\phi - \pi(g_n)\phi, \psi \rangle|$$

$$= |\lim_{n \to \infty} \langle \pi(g_n u_- g_n^{-1})\pi(g_n)\phi - \pi(g_n)\phi, \psi \rangle|$$

$$= |\lim_{n \to \infty} \langle \pi(g_n)\phi, \pi(g_n u_- g_n^{-1})\psi - \psi \rangle|$$

$$\leq \lim_{n \to \infty} \|\pi(g_n)\phi\| \cdot \|\pi(g_n u_- g_n^{-1} - e)\psi\| = 0,$$

as $\lim_{n \to \infty} g_n u_- g_n^{-1} = e$. We conclude that $E\pi(u_-) = E$, for every $u_- \in U_1^-$. In the same way one proves that $\pi(u_+)E = E$, for every $u_+ \in U_1^+$. This proves the claim.

By the claim we obtain that, for every $\phi \in \mathcal{H}$, the vector $E(\phi)$ (respectively, $E^*(\phi)$) is $U_1^+$ (respectively, $U_1^-$) invariant. In particular, this is the case for the vectors $E(v)$ and respectively, $E^*(w)$.

Recall that $E$ is normal and different from zero. Thus, we have that $E^*E = EE^* \neq 0$ (otherwise $0 = \langle E^*E(\phi), \phi \rangle = \|E(\phi)\|^2$ for every $\phi \in \mathcal{H}$ contradicting $E \neq 0$). In this way we are able to find a non-zero vector $\psi \in E(\mathcal{H}) \cap E^*(\mathcal{H}) \neq \{0\} \subset \mathcal{H}$ which is $(N_1^+, N_1^-)$-invariant, so also $G$-invariant. The contradiction follows and the lemma stands proven. \(\square\)
Theorem 3.2. Let $G$ be a second countable, locally compact group having the following properties:

i) $G$ admits a decomposition $K_1A^+K_2$, where $K_1,K_2 \subset G$ are compact subsets and $A^+$ is an abelian sub semi-group of $G$;

ii) for all sequences $\alpha = \{g_n\}_{n>0} \subset A^+$, with $g_n \to \infty$, we have $G = \langle U_\alpha^+, U_\alpha^- \rangle$.

Then $G$ has the Howe–Moore property.

Proof. Notice that by Lemma 2.4 and the fact that $G$ is also separable, it is enough to prove the Howe–Moore property only for unitary representations that are over separable Hilbert spaces.

Therefore, let $(\pi, \mathcal{H})$ be a unitary representation of $G$, without non-zero $G$-invariant vectors and where $\mathcal{H}$ is a separable Hilbert space. Suppose that not all matrix coefficients of $(\pi, \mathcal{H})$ vanish at $\infty$.

Using Lemma 2.9 there exists a sequence $\{g_n\}_{n>0} \subset A^+$ and two non-zero vectors $v, w \in \mathcal{H}$ such that $g_n \to \infty$ and $|\langle \pi(g_n)v, w \rangle| \to 0$. By passing to a subsequence $\{g_{n_k}\}_{k>0}$ and using the separability of $\mathcal{H}$ (see Lemma 2.13), assume that $\{\pi(g_{n_k})\}_{n_k}$ weakly converges to an operator $E$ and that $|\langle \pi(g_{n_k})v, w \rangle| > C > 0$, for every $n_k$ and where $C$ a constant. Applying Lemma 3.1 to the sequence $\alpha = \{\pi(g_{n_k})\}_{n_k}$ we obtain a contradiction. Our criterion stands proven.

\[\square\]

4 Unified proof of known examples

As announced, in this section we apply the criterion provided by Theorem 3.2 to the classes of groups mentioned in the introduction. Thereby we deduce, in a unified fashion, that the Howe–Moore property holds for all those classes.

4.1 Real Lie groups

For the class of connected simple real Lie groups with finite centre the proof is the same as the one given in [BM00]; still we outline briefly the main ideas.

It is a well-known fact that a semi-simple real Lie group $G$, with finite center, has a $KA^+K$ decomposition (called the polar decomposition) where $K$ is a maximal compact subgroup, $A \subset G$ is the closed subgroup corresponding to the maximal abelian sub-algebra of the Lie algebra of $G$ and $A^+ \subset A$ the corresponding positive sub semi-group part (see [BM00, Chapter III] for more details).

Therefore, to use our criterion Theorem 3.2 it is enough to prove that for every sequence $\alpha = (g_n)_{n \geq 1} \subset A^+$ with $g_n \to \infty$ one has that $\langle U_\alpha^+, U_\alpha^- \rangle = G$. More exactly, we have the following lemma (see [BM00 Chap. III, Lemma 1.8]):

Lemma 4.1. i) For every $a \in A^+$, the subgroup $\langle U_a^+, U_a^- \rangle$ is normal and non-discrete in $G$. 

9
For every $\alpha = (g_n)_{n \geq 1} \subset A^+$, with $g_n \to \infty$, there exists $b \in A^+$ such that 

$$\langle U^+_a, U^-_a \rangle = \langle U^+_b, U^-_b \rangle; \text{ moreover } N^+_b = N^+_a.$$ 

The proof of this lemma uses the Lie algebra of $G$ and the root system.

### 4.2 Euclidean building groups

Let us now turn our attention to the totally disconnected analogs of semi-simple real Lie groups; namely closed groups acting by automorphisms and strongly transitively on locally finite thick Euclidean buildings.

**Notation 4.2.** To fix the notations, let us denote a locally finite thick Euclidean building by $\Delta$ (for the definition of a building and the related concepts the reader can consult [AB08]). Fix for what follows an apartment $A$ in $\Delta$, a chamber $C$ in $A$ and a special vertex $x_0$ of $C$. By $\text{Ch}(B)$ we denote the set of all chambers of an apartment $B$ in $\Delta$ and by $\partial B$ its corresponding apartment in the spherical building at infinity $\partial \Delta$.

We make use also of the following:

**Definition 4.3.** Let $\Delta$ be a Euclidean or a spherical building and $G$ be a group acting by automorphisms on $\Delta$. We say that $G$ acts **strongly transitively** on $\Delta$ if for any two pairs $(A_1, c_1)$ and $(A_2, c_2)$ consisting of an apartment $A_i$ and a chamber $c_i \in \text{Ch}(A_i)$, there exists $g \in G$ such that $g(A_1) = A_2$ and $g(c_1) = c_2$.

**Remark 4.4.** Recall that the subgroup of all type-preserving automorphisms of $\Delta$ is of finite index in $\text{Aut}(\Delta)$. Therefore, if a subgroup of $\text{Aut}(\Delta)$ enjoys the Howe–Moore property then, by Proposition [2.10] that group must be type-preserving.

For the rest of this article, by Remark [4.3] we design $G$ to be a closed, strongly transitive and type-preserving subgroup of $\text{Aut}(\Delta)$. For most of such groups $G$ we want to verify the two conditions given in Theorem [3.2]. The first one is the well-known polar decomposition whose proof is recalled in the next subsection.

### 4.2.1 Polar decomposition

Let $\text{Stab}_G(A)$, respectively $\text{Fix}_G(A)$, be the stabilizer subgroup, respectively the pointwise stabilizer subgroup, in $G$ of an apartment $A$ of $\Delta$.

Recall that $\text{Stab}_G(A)/\text{Fix}_G(A)$ is the Weyl group $W$, corresponding to the Euclidean building $\Delta$ and that $W$ is generated by the reflexions through the walls of a chamber $C \in \text{Ch}(A)$. Another well-known fact is that $W$ contains a maximal abelian normal subgroup isomorphic to $\mathbb{Z}^n$, whose elements are Euclidean translation automorphisms of the apartment $A$ and $n$ is the Euclidean dimension of $A$. Denote this maximal abelian normal subgroup by $A$ and remark that its elements correspond to hyperbolic automorphisms of $\Delta$. Let $x_0 \in A$ be a special vertex and let $Q$ be a sector in $A$ based at $x_0$. Define $A^+ \subset A$ to be the sub semi-group consisting of translations mapping $x_0$ in $Q$. Notice that $W_{x_0}$ is transitive on the set of sectors of $A$ that are based at $x_0$. Therefore,
for every $a \in A$, there exists $k \in W_{x_0}$ such that $kak^{-1} \in A^+$. The subset $A^+$ is the desired ‘maximal abelian’ and ‘positive’ sub semi-group part of $A$.

Take now $g \in G$ and let $\mathcal{B}$ be an apartment in $\Delta$ such that $C, g(C) \in \text{Ch}(\mathcal{B})$. As $G$ is strongly transitive, there exists $k \in G$ such that $k(\mathcal{B}) = \mathcal{A}$ and $k(C) = C$ pointwise. Therefore $k \in \text{Stab}_G(x_0)$. As $G$ is type-preserving, $kg(x_0)$ is a special vertex of the same type as $x_0$. Therefore, using the fact that $W$ is simply transitive on special vertices of the same type, there exists a translation automorphism $a$ of the apartment $\mathcal{A}$ sending $kg(x_0)$ into $x_0$. We conclude that $akg(x_0) = x_0$ and thus $akg \in \text{Stab}_G(x_0)$.

By writing the element $a$ using elements from $A^+$ and $\text{Stab}_G(x_0)$, we have that $g \in \text{Stab}_G(x_0)A^+\text{Stab}_G(x_0)$. Therefore the polar decomposition of the group $G$ is proven, as $\text{Stab}_G(x_0)$, being the stabilizer of the vertex $x_0$, is compact and open in $G$. To conclude, we have proved the following:

**Lemma 4.5.** Let $G$ be a closed, strongly transitive and type-preserving subgroup of $\text{Aut}(\Delta)$. Take $\mathcal{A}$ an apartment in $\Delta$ and $x_0$ be a special vertex in $\mathcal{A}$. Then $G = \text{Stab}_G(x_0)A^+\text{Stab}_G(x_0)$.

**Remark 4.6.** Notice that, for a general closed, strongly transitive and type-preserving subgroup $G$ of $\text{Aut}(\Delta)$, its corresponding abelian group $A < W$ does not necessarily lift to an abelian subgroup of $G$. Still, this is the case if we consider that $G$ is a semi-simple algebraic group over a non Archimedean local field. By the theory of Bruhat–Tits, such a group gives rise to a Euclidean building where the group $G$ acts by automorphisms and strongly transitively. The abelian group $A < W$ is in fact the restriction to $\mathcal{A}$ of a maximal split torus of $G$, which is abelian.

Related to the polar decomposition from Lemma 4.5, we recall another well-known decomposition of the group $G$.

Let $c$ be an ideal chamber in $\partial \mathcal{A}$. Denote by

$$G_c^0 := \{g \in G \mid g(c) = c \text{ and } g \text{ fixes at least one vertex of } \Delta\} \quad (1)$$

the ‘pointwise’ stabilizer subgroup in $G$ corresponding to $c \in \text{Ch}(\partial \mathcal{A})$. Remark that $G_c^0$ is a closed subgroup of $\text{Stab}_G(c)$ and does not contain any hyperbolic automorphisms of $\Delta$.

Take $g \in G$ and let $\mathcal{B}$ be an apartment in $\Delta$ such that $g^{-1}(C) \in \text{Ch}(\mathcal{B})$ and $c \in \text{Ch}(\partial \mathcal{B})$. Remark that $\mathcal{A}$ and $\mathcal{B}$ have a sector in common, corresponding to the chamber at infinity $c$. Thus, by the strongly transitive action, there exists $n \in G_c^0$ such that $n(\mathcal{B}) = \mathcal{A}$. We obtain that $ng^{-1}(C) \in \text{Ch}(\mathcal{A})$. As $G$ is type-preserving, there exists a translation automorphism $a \in A$ of the apartment $\mathcal{A}$ such that $an^g(x_0) = x_0$. From here we conclude that $an^g \in \text{Stab}_G(x_0)$ and thus $g \in \text{Stab}_G(x_0)AG_c^0$. Therefore

$$G = \text{Stab}_G(x_0)AG_c^0. \quad (2)$$
4.2.2 Levi conditions

Let us now start verifying the second condition given by Theorem 3.2, for a closed, strongly transitive and type-preserving subgroup $G$ of $\text{Aut}(\Delta)$. Its first step is given by the following well-known proposition; for the convenience of the reader we include its proof.

Regarding the closed subgroup $G^0_c$ defined in (1), by the strongly transitive action of $G$ on $\Delta$, we have that $G^0_c$ acts transitively on the set $\text{Opp}(c)$ of all chambers opposite $c$ of $\text{Ch}(\partial \Delta)$. Indeed, let $c_1 \neq c_2 \in \text{Opp}(c)$. Denote by $A_1$ and respectively, by $A_2$, the unique apartments of $\Delta$ such that $c_1, c \in \text{Ch}(\partial A_1)$ and respectively, $c_2, c \in \text{Ch}(\partial A_2)$. Let $Q \subset A_1 \cap A_2$ be a sector pointing to the chamber at infinity $c$ and choose a chamber $C$ of $\text{Ch}(\Delta)$ contained in the interior of $Q$. Then, by the strong transitive action of $G$, there exists $g \in G$ such that $g(C) = C$ and $g(A_1) = A_2$. In addition, we have that $g(Q) = Q$ pointwise; therefore $g \in G^0_c$ and $g(c_1) = c_2$.

**Proposition 4.7.** Let $G$ be a closed, strongly transitive and type-preserving subgroup of $\text{Aut}(\Delta)$. Let $A$ be an apartment of $\Delta$ and take $c_+ \in \text{Ch}(\partial A)$. Denote by $c_-$ the chamber opposite $c_+$ in $\partial A$.

Then $G = \langle G^0_{c+}, G^0_{c-} \rangle$.

Before starting the proof, we state the next useful lemma.

**Lemma 4.8.** Let $G$ be a closed, strongly transitive and type-preserving subgroup of $\text{Aut}(\Delta)$. Let $A$ be an apartment of $\Delta$ and take $c_+ \in \text{Ch}(\partial A)$. Denote by $c_-$ the chamber opposite $c_+$ in $\partial A$.

Then $\text{Stab}_G(A) = \text{Stab}_G(\partial A) \leq \langle G^0_{c+}, G^0_{c-} \rangle$.

**Proof.** The equality $\text{Stab}_G(A) = \text{Stab}_G(\partial A)$ is straightforward.

Following [CC] proof of Lemma 3.5 we start with a basic observation. Let $A'$ be an apartment of $\Delta$ such that the intersection $A \cap A'$ is a half-apartment. We claim that there is some $u \in \langle G^0_{c+}, G^0_{c-} \rangle$ mapping $A'$ to $A$ and fixing $A \cap A'$ pointwise. Indeed, because $c_+, c_-$ are opposite in $\partial A$, they are separated by any wall of $A$. Thus, $A \cap A'$, being a half-apartment, contains a sector $Q$ corresponding either to $c_+$, or to $c_-$. We apply the strong transitivity of $G$; there exists an element $g \in G$ fixing pointwise a chamber in the interior of the sector $Q$ and sending $A'$ to $A$. Then $g \in \langle G^0_{c+}, G^0_{c-} \rangle$.

Let now $M$ be a wall of $A$. Let $H$ and $H'$ be the two half-apartments of $A$ determined by $M$. Since $\Delta$ is thick, there exists a half-apartment $H''$ such that $H \cup H''$ and $H' \cup H''$ are both apartments of $\Delta$. By the above claim, we can find an element $u \in \langle G^0_{c+}, G^0_{c-} \rangle$ fixing $H$ pointwise and mapping $H'$ to $H''$. Similarly, there are elements $v, w \in \langle G^0_{c+}, G^0_{c-} \rangle$ fixing $H'$ pointwise and such that $v(H'') = H$ and $w(H) = w^{-1}(H')$. Now we set $r := vuw$. By construction $r$ fixes pointwise the wall $M$ and $r \in \langle G^0_{c+}, G^0_{c-} \rangle$.

Moreover we have

$$r(H) = vuu^{-1}(H') = v(H') = H'$$

and

$$r(H') = vu(H') = v(H'') = H,$$
so that \( r \) swaps \( H \) and \( H' \). It follows that \( r \) stabilizes the apartment \( A \) and acts on \( A \) as the reflection through the wall \( M \). Since this holds for an arbitrary wall of \( A \) and \( \text{Stab}_G(A)/\text{Fix}_G(A) \), being the Weyl group \( W \), is generated by reflections through the walls of a chamber \( C \in \text{Ch}(A) \), our conclusion follows.

**Proof of Proposition 4.7.** Take \( g \in G \) and let \( B \) an apartment of \( \Delta \) such that \( g(c_+), c_+ \in \text{Ch}(\partial B) \). Then \( A \) and \( B \) have a sector in common, corresponding to the chamber at infinity \( c_+ \). By the strong transitivity of \( G \), take \( h_1 \in G^0_{c_+} \) such that \( h_1(B) = A \). Therefore \( h_1g(c_+) \in \text{Ch}(\partial A) \). Recall that the strong transitivity of \( G \) on \( \Delta \) implies that \( G \) acts strongly transitively on \( \partial \Delta \) (see [Gar97, Section 17.1]). Applying Lemma 4.8, there exists \( h_2 \in \text{Stab}_G(\partial A) \leq \langle G^0_{c_+}, G^0_{c_-} \rangle \) such that \( h_2h_1g(A) = c_+ \). Thus \( h_2h_1g \) and \( A \) have a sector in common corresponding to the chamber at infinity \( c_+ \). Take now \( h_3 \in G^0_{c_+} \) with \( h_3h_2h_1g(A) = A \). Therefore \( h_3h_2h_1g \in \text{Stab}_G(A) \) and by Lemma 4.8 the conclusion follows.

**‘Algebraic’ Levi decomposition**

Recall from [BW04] the following general theory. Let \( G \) be a totally disconnected locally compact group and take \( a \in G \). Let

\[
P^+_a := \{ g \in G \mid \{ a^{-n}ga^n \}_{n \in \mathbb{N}} \text{ is bounded} \}.
\]

(3)

In the same way, but using \( a^n ga^{-n} \), we define \( P^-_a \). Following [BW04, Section 3], \( P^+_a \) is a closed subgroup of \( G \) and denote

\[
U^+_a := \{ g \in G \mid \lim_{n \to \infty} a^{-n}ga^n = e \}.
\]

(4)

By [BW04, Section 3], \( P^+_a \) and \( U^+_a \) are called the parabolic, respectively the contraction, subgroups associated to \( a \), where in general \( U^+_a \) is not closed. Moreover, from the algebraic point of view, we have the following Levi decomposition:

**Theorem 4.9.** (See [BW04 Proposition 3.4, Corollary 3.17]) Let \( G \) be a totally disconnected locally compact group which is also metrizable. Let \( a \in G \). Then \( P^+_a = U^+_a M_a \), where \( M_a := P^+_a \cap P^-_a \). Moreover, \( U^+_a \) is normal in \( P^+_a \).

Specialized it to our context we obtain:

**Corollary 4.10.** Let \( G \) be a closed, strongly transitive and type-preserving subgroup of \( \text{Aut}(\Delta) \). Let \( a \in G \) be a hyperbolic element. Then \( P^+_a = U^+_a M_a \), where \( M_a := P^+_a \cap P^-_a \). Moreover, \( U^+_a \) is normal in \( P^+_a \).

**Remark 4.11.** In the setting of a locally finite Euclidean building \( \Delta \), a subset \( F \subset \text{Aut}(\Delta) \) is called bounded if there exists a point \( y \in \Delta \) such that the set \( F \cdot y \) is a bounded subset of \( \Delta \). For equivalent definitions see [AB08 Lemma 11.32]. Those characterizations are useful and used in what follows when working with elements of \( P^+_a \).
‘Geometric’ Levi decomposition

This subsection proposes to link the ‘algebraic’ Levi decomposition from Corollary 4.10 with the subgroup $G^a_c$ defined in (1), a key ingredient being given by the following:

**Proposition 4.12.** Let $G$ be a closed, non-compact and type-preserving subgroup of $\text{Aut}(\Delta)$. Let $\mathcal{A}$ be an apartment in $\Delta$ and assume there exists an hyperbolic automorphism $a \in \text{Stab}_G(\mathcal{A})$. Denote its attracting endpoint by $\xi_+ \in \partial \mathcal{A}$ and let $c_+ \in \text{Ch}(\partial \mathcal{A})$, with $\xi_+ \in c_+$. Let $G_{c_+} := \{ g \in G \mid g(c_+) = c_+ \}$ and $G_{\xi_+} := \{ g \in G \mid g(\xi_+) = \xi_+ \}$.

Then $G_{c_+} \leq P^+ = G_{\xi_+} = G_\sigma$, where $\sigma$ is the unique simplex in $\partial \mathcal{A}$ such that $\xi_+$ is contained in the interior of $\sigma$ ($\sigma = \xi_+$ if and only if $\xi_+$ is a vertex). In particular, we obtain that $P^+_a \cap P^-_a = G_{(\xi_-, \xi_+)}$.

**Proof.** The equality $G_{\xi_+} = G_\sigma$ is immediate as $G$ is type-preserving.

Let us first prove that $P^+_a \subset G_{\xi_+}$.

Take $g \in P^+_a$ and let $x_0$ be a special vertex of $\mathcal{A}$. By the definition of $P^+_a$, the set \{a^{-n}ga^n(x_0) \mid n \in \mathbb{N}\} is a bounded subset of $\Delta$ and thus is finite. Extract a subsequence $n_k \to \infty$ such that $a^{-n_k}ga^{n_k}(x_0) = y$, for every $n_k$. As $G$ is type-preserving, the point $y$ is also a special vertex of $\Delta$.

Now, because $a^{n_k}(x_0) \to \xi_+$ and $a^{n_k}(y) \to \xi_+$ (in the cone topology of $\Delta \cup \partial \Delta$), one can conclude that $g(\xi_+) = \xi_+$. Therefore $g \in G_{\xi_+}$.

Let us show that $G_{\xi_+} \subset P^+_a$.

Let $g \in G_{\xi_+}$. As $g(\xi_+) = \xi_+$ there exists a geodesic ray in $\mathcal{A}$, say $[y, \xi_+]$, such that $g([y, \xi_+]) \subset \mathcal{A}$ is parallel to $[y, \xi_+]$. Moreover, we have that $\text{dist}_\mathcal{A}(g(t), t) = \text{dist}_\mathcal{A}(g(y), y)$, for every $t \in [y, \xi_+]$. To prove that $g \in P^+_a$ it is enough to show that the set $\{a^{-n}ga^n(z) \mid n \in \mathbb{N}\}$ is a bounded subset of $\Delta$, for some point $z \in \mathcal{A}$. Take $z = y$. Because $a$ is a hyperbolic element in $\text{Stab}_G(\mathcal{A})$, $a^n(y) \in [y, \xi_+]$. From here, we immediately conclude that $\{a^{-n}ga^n(z) \mid n \in \mathbb{N}\}$ is indeed a bounded set.

The fact that $G_{c_+} \subset P^+_a$ is an immediate consequence of the equality $P^+_a = G_{\xi_+}$, as $G$ is type-preserving and $G_{c_+} \leq G_{\xi_+}$.

**Remark 4.13.** For a general hyperbolic element $a \in \text{Stab}_G(\mathcal{A})$ we do not necessarily have the equality $P^+_a = G_{c_+}$ in Proposition 4.12. However, if $a$ is a strongly regular hyperbolic element of $\text{Stab}_G(\mathcal{A})$ (see [CC] Definition 2.2 and Lemma 2.3), the equality $P^+_a = G_{c_+}$ holds, as in this case $G_{c_+} = G_{\xi_+}$. In addition, if we take $\Delta$ to be a locally finite tree, the equality $P^+_a = G_{c_+}$ is always verified as the chambers at infinity are just the ends of the tree, which are points.

By combining Proposition 4.12 and Corollary 4.10 we obtain the geometric Levi decomposition:

**Corollary 4.14.** Let $G$ be a closed and type-preserving subgroup of $\text{Aut}(\Delta)$. Let $\mathcal{A}$ be an apartment in $\Delta$ and assume there exists a hyperbolic automorphism $a \in \text{Stab}_G(\mathcal{A})$. 

Denote its attracting endpoint by $\xi_+ \in \partial A$ and let $\sigma$ be a simplex in $\partial A$ such that $\xi_+ \in \sigma$. Let also $c_+ \in \text{Ch}(\partial A)$ with $\xi_+ \in c_+$.

Then $G_\sigma = U_+^+(M_a \cap G_\sigma)$, where $M_a := P_a^+ \cap P_a^-$. In particular, $G_\sigma^0 = U_+^+(M_a \cap G_\sigma^0)$. In addition $U_+^+$ is normal in $G_\sigma^0$, respectively, $G_\sigma$.

Proof. By the definition of $U_+^+$ one can easily verify that $U_+^+ \leq G_\sigma^0 \leq G_\sigma \leq P_a^+$. The conclusion follows by applying Corollary 4.10.

Furthermore, by Proposition 4.7 and Corollary 4.14 we obtain:

**Corollary 4.15.** Let $G$ be a closed, strongly transitive and type-preserving subgroup of $\text{Aut}(\Delta)$. Let $A$ be an apartment of $\Delta$ and let $a \in \text{Stab}_G(A)$ be a hyperbolic automorphism. Then $\langle U_+^+, U_-^- \rangle$ is normal in $G$.

Proof. Let $c_-, c_+ \in \text{Ch}(\partial A)$ be two opposite ideal chambers containing the repelling point and respectively the attracting point of the hyperbolic element $a$. By Proposition 4.7 we have that $G = \langle G_{c_-}^0, G_{c_+}^0 \rangle$. Therefore, to prove that $\langle U_+^+, U_-^- \rangle$ is normal in $G$, it is enough to verify that, for every $g \in G_{c_-}^0$, we have that $gU_+^+g^{-1} \in \langle U_+^+, U_-^- \rangle$. Indeed, using the decomposition of $G_{c_\pm}^0$ given by Corollary 4.14 and the fact that $U_+^+$ is normal in $G_{c_\pm}^0$, the conclusion follows.

4.2.3 The proof of the Howe–Moore property

Using all the ingredients presented in the above subsections, the goal here is to provide the proof of the following theorem:

**Theorem 4.16.** Let $G$ be an isotropic simple algebraic groups over a non Archimedean local field or a closed, topologically simple subgroup of $\text{Aut}(T)$ that acts 2-transitively on the boundary $\partial T$, where $T$ is a bi-regular tree with valence $\geq 3$ at every vertex. Then $G$ admits the Howe–Moore property.

To prove Theorem 4.16 in the case of algebraic groups, it remains to verify the second condition given by Theorem 3.2, namely, the analogue of Lemma 4.1. As in the case of connected simple real Lie groups with finite center, the analogue lemma uses the theory of root group datum related to Euclidean buildings; therefore, we briefly recall some definitions and state some known properties of this theory from [Wei08, AB08, Ron89]. We mention that the proof of the analogue of Lemma 4.1 stated in Proposition 4.25 for the case of Euclidean buildings, works in the same spirit as for real Lie groups.

**Definition 4.17.** Let $X$ be a Euclidean or a spherical building. A half-apartment $h$ of $X$ is called a root of $X$. By abuse of notation, we use $\partial h$ to denote the boundary wall in $X$ which is determined by $h$.

Moreover, if $X$ is a spherical building, the root group $U_h$ corresponding to a root $h$ of $X$ is defined to be the set of all $g \in \text{Aut}(X)$ such that $g$ fixes pointwise $h$ and also the star of every panel contained in $h \setminus \partial h$. 

15
Definition 4.18. Let $X$ be a thick spherical building. For a root $h$ of $X$, we denote by $\mathcal{A}(h)$ the set of all apartments in $X$ that contain $h$. We say that $X$ is Moufang if, for every root $h$ of $X$, the root group $U_h < \text{Aut}(X)$ is transitive on $\mathcal{A}(h)$.

Recall that for a semi-simple algebraic group $G$ over a non Archimedean local field, by [BT72] one associates a locally finite thick Euclidean building $\Delta$ where $G$ acts by automorphisms and strongly transitively. More precisely:

Definition 4.19. Let $G$ be a semi-simple algebraic group over a non Archimedean local field $k$, of rank $\geq 1$. Let $G = G(k)$ be the group of all $k$-rational points of $G$. By [BT72], to the group $G$ one associates a locally finite thick Euclidean building $\Delta$ where $G$ acts by type-preserving automorphisms and strongly transitively. Moreover, by [BT72], the spherical building $\partial \Delta$ at infinity of $\Delta$ is Moufang. Let $G^+ := \langle U_h \leq G \mid h \text{ is a root of } \partial \Delta \rangle$. It is known that $G^+$ is a closed normal subgroup of $G$ and that the factor group $G/G^+$ is compact (see [Mar91, Thm. 2.3.1]). We call $G^+$ an isotropic simple algebraic group over the non Archimedean local field $k$. From its definition, notice that $G^+$ acts by type-preserving automorphisms and also strongly transitively on $\Delta$.

Proposition 4.20. (See [Wei08] Prop. 13.2 and 13.5) Let $\Delta$ be a Euclidean building such that its corresponding building at infinity $\partial \Delta$ is Moufang. Let $\mathcal{A}$ be an apartment of $\Delta$ and let $h$ be a root of $\partial \mathcal{A}$. For $u \in U_h^*$ let $h_u := \mathcal{A} \cap u(\mathcal{A})$.

Then $h_u$ is a root of $\mathcal{A}$ such that its boundary at infinity $h_u(\infty) = h$. Moreover, $u$ acts trivially on $h_u$. Conversely, let $\mathcal{H}$ be a root of $\mathcal{A}$ such that its boundary at infinity $\mathcal{H}(\infty) = h$. Then there exists $u \in U_h^*$ such that $\mathcal{H} = h_u$.

Definition 4.21. Let $\Delta$ be a Euclidean building such that its corresponding building at infinity $\partial \Delta$ is Moufang. Let $\mathcal{H}$ be a root of an apartment $\mathcal{A}$ of $\Delta$ and denote $h := \mathcal{H}(\infty)$ the corresponding root in $\partial \mathcal{A}$. With respect to $U_h$, the affine root group corresponding to $\mathcal{H}$ is the set $U_\mathcal{H} := \{ u \in U_h^* \mid h_u = \mathcal{H} \} \cup \text{id}$, where $h_u := \mathcal{A} \cap u(\mathcal{A})$, for $u \in U_h^*$.

Proposition 4.22. (See [BT72] Prop. 7.4.33) Let $G$ be a semi-simple algebraic group over a non Archimedean local field $k$ and let $G = G(k)$ be the group of all $k$-rational points of $G$. Denote by $\Delta$ the corresponding locally finite thick Euclidean building on which $G$ acts by type-preserving automorphisms and strongly transitively. Let $\mathcal{H}$ be a root of $\Delta$ and let $x \in \mathcal{H}$. Then the radius of the ball of $\Delta$ around $x$ which is fixed pointwise by $U_{\mathcal{H}} < G$ goes to infinity as the distance of $x$ to $\partial \mathcal{H}$ goes to infinity.

From Propositions 4.22 and 4.20 we immediately obtain:

Corollary 4.23. Let $G$ be a semi-simple algebraic group over a non Archimedean local field $k$ and let $G = G(k)$ be the group of all $k$-rational points of $G$. Denote by $\Delta$ the corresponding locally finite thick Euclidean building on which $G$ acts by type-preserving automorphisms and strongly transitively. Let $\mathcal{A}$ be an apartment of $\Delta$ and let $h$ be a root of $\partial \mathcal{A}$. Let $a = \{a_n\}_{n>0} \subset \text{Stab}_G(\mathcal{A})$ with $a_n \to \infty$. Assume that $a_n(x_0) \to \xi \in h \setminus \partial h$, in the cone topology, where $x_0 \in \mathcal{A}$ is some special vertex.
Then $U_h \leq U_a^+$. In particular, we obtain that $U_h \leq U_a^+$, for every hyperbolic element $a \in \text{Stab}_G(A)$ whose attracting endpoint $\xi_+ \in h \setminus \partial h$.

Proof. As $U_h$ is the union of its corresponding affine root groups $U_H$, it is enough to prove that $U_H \leq U_a^+$. Indeed, let $u \in U_H$. As $a_n(x_0) \to \xi \in h \setminus \partial h$, in the cone topology, where $x_0$ is a special vertex of $A$, we have that the intersection of the geodesic ray $[x_0, \xi]$ with the root $H$ is a geodesic ray with endpoint $\xi$. Therefore, for every standard open neighborhood $V \subset H$ of $\xi$ with respect to the cone topology of $A$, there exists $N$ such that $a_n(x_0) \in V \subset H$, for every $n \geq N$. By Proposition 4.22 we immediately obtain that $u \in U_a^+$.

Another important property is recorded by the following corollary.

Corollary 4.24. Let $G$ be a semi-simple algebraic group over a non Archimedean local field $k$ and let $G = G(k)$ be the group of all $k$-rational points of $G$. Denote by $\Delta$ the corresponding locally finite thick Euclidean building on which $G$ acts by type-preserving automorphisms and strongly transitively. Let $A$ be an apartment of $\Delta$ and let $a \in \text{Stab}_G(A)$ be a hyperbolic element whose attracting endpoint in $\partial A$ is denoted by $\xi_+$. Let $\sigma$ be the unique simplex in $\partial A$ such that $\xi_+$ is contained in the interior of $\sigma$ and denote by $\text{St}(\sigma)$ the star of $\sigma$ in $\partial A$.

Then $U_a^+ = \{u \in h \mid h \text{ is a root of } \partial A \text{ with } \text{St}(\sigma) \subset h\}$.

Proof. The conclusion follows by combining Corollary 4.14 with the theory of root group datum [Ron89] Thm. 6.18.

The analogue of Lemma 4.1 is given by the following proposition.

Proposition 4.25. Let $G$ be a semi-simple algebraic group over a non Archimedean local field $k$ and let $G = G(k)$ be the group of all $k$-rational points of $G$. Denote by $\Delta$ the corresponding locally finite thick Euclidean building on which $G$ acts by type-preserving automorphisms and strongly transitively. Let $A$ be the apartment that corresponds to the abelian sub semi-group $A^+$ of the Weyl group $W$ of $G$.

Let $\alpha = \{a_n\}_{n>0} \subset A^+$ with $a_n \to \infty$ and such that $a_n(x_0) \to \xi \in \partial A$, for some special vertex $x_0 \in A$. Then there exists a hyperbolic element $b \in \text{Stab}_G(A)$ such that $U_b^+ \leq U_a^+$.

Proof. Let $x_0$ be a fixed special vertex in the apartment $A$ and let $\{\gamma_1, \ldots, \gamma_m\}$ be the basis of $A^+$ described in the beginning of Section 4.2. Moreover, we can choose the basis $\{\gamma_1, \ldots, \gamma_m\}$ such that the attracting endpoint of $\gamma_j$, for every $j \in \{1, \ldots, m\}$, is a vertex in $\partial A$ (i.e., it is a vertex of the chamber at infinity determined by the sector that defines $A^+$). Let $\sigma$ be the unique simplex of $\partial A$ that contains $\xi$ in its interior ($\xi = \sigma$ if and only if $\xi$ is a vertex in $\partial A$). Let $\{\gamma_{i_1}, \ldots, \gamma_{i_t}\}$ be the set of the elements of $\{\gamma_1, \ldots, \gamma_m\}$ whose attracting endpoints determine the simplex $\sigma$.

Define $b := \gamma_{i_1} \cdots \gamma_{i_t}$ and notice that $b$ is a hyperbolic element in $\text{Stab}_G(A)$. Moreover, the attracting endpoint $\xi_+$ of $b$ and the point $\xi$ are contained in the interior of the simplex $\sigma$ of $\partial A$.
Apply Corollary 4.24 to \( b \) and \( \sigma \). Then, by Corollary 4.23 we obtain that \( U_b^\pm \subset U_{\alpha}^\pm \).

Proof of Theorem 4.16. By Lemma 2.4 and Remark 2.5 it is enough to verify the Howe–Moore property only for separable Hilbert spaces.

Let \( G \) be an isotropic simple algebraic group over a non Archimedean local field or a closed, topologically simple subgroup of \( \text{Aut}(T) \) that acts 2-transitively on the boundary \( \partial T \), where \( T \) is a bi-regular tree with valence \( \geq 3 \) at every vertex. For such \( G \), we verify the two conditions of the Theorem 3.2. In both cases, the first condition of Theorem 3.2 is verified by applying Lemma 4.5 to \( G \).

Let us verify the second condition of Theorem 3.2. Notice that, in the case of a bi-regular tree, the corresponding group \( A^+ \) of \( G \), given by the polar decomposition of \( G \), is generated by a single hyperbolic element \( \alpha \in G \). Therefore, the second condition follows immediately from Corollary 4.15 applied to \( G \).

When \( G \) is an isotropic simple algebraic group over a non Archimedean local field, to obtain the Howe–Moore property, it is enough to verify the second condition of Theorem 3.2 only for a sequence \( \alpha = \{a_n\}_{n>0} \subset A^+ \) with \( a_n \to \infty \) and such that \( a_n(x_0) \to \xi \in \partial A \), for some special vertex \( x_0 \in A \). This follows by applying to \( \alpha = \{a_n\}_{n>0} \) Proposition 4.25 and Corollary 4.15. Notice that, for every hyperbolic element \( b \in \text{Stab}_G(A) \), the group \( \langle U_b^+, U_b^- \rangle \), which is normal in \( G \), acts non-trivially on \( A \). By \cite{Tit64, Main Theorem}, we obtain that for every hyperbolic element \( b \in \text{Stab}_G(A) \), the group \( \langle U_b^+, U_b^- \rangle = G \). The theorem stands proven.
