Endotracheal intubation is the gold standard for airway management in general anesthesia. However, airway patency is not guaranteed by keeping the endotracheal tube (ETT) in place. Sometimes, the ETT itself may become a cause of airway obstruction; there are some reports on airway obstruction related to reinforced tube malfunction. We report a rare case with an obstruction of reinforced endotracheal tubes caused by dissection of the internal wall. Recognition of the possibility of airway obstruction due to a rare cause and monitoring patients vigilantly during anesthesia is very important for patient safety.

Key Words: Airway obstruction, Dissection, Endotracheal tube.

CASE REPORT

A 67-year-old woman (164 cm, 68 kg) who was previously healthy, except for being a hepatitis C virus carrier, was scheduled for a posterior lumbar interbody fusion because of lumbar spondylolisthesis and spinal stenosis. After using standard monitoring methods, including electrocardiography, a non-invasive blood pressure measuring device, and pulse oximetry; 0.2 mg glycopyrrolate, 20 mg lidocaine, and 120 mg propofol were injected intravenously. After confirmation of unconsciousness, rocuronium 40 mg was injected for paralysis and 2 minimum alveolar concentration (MAC) of sevoflurane with 100% O2 (> 5 L/min) were administered via face mask with manual ventilation. Under direct laryngoscopy, reinforced ETT (Mallinckrodt®, Covidien Inc., USA) with 7.0-mm internal diameter was intubated without difficulty. Normal breath sounds were heard equally in both lungs. The ETT was fixed at 21 cm on the mouth angle. The lungs were mechanically ventilated (volume-controlled mode with tidal volume 500 ml and respiratory rate 12 breaths/min) using Dräger Primus Workstation (Dräger Medical, Germany). The anesthesia was maintained with 1 MAC sevoflurane and a
mixture of 1.5 L to 1.5 L of O₂ and N₂O. Five minutes after intubation, the patient was stable with ETCO₂ 35 mmHg, peak inspiratory pressure (PIP) 17–18 cmH₂O, and SpO₂ 99%. After the patient was placed in a prone position, there was a mild increase in PIP to 20 cmH₂O. However, lung sounds were normal. Thirty minutes after the patient’s position changed, the PIP was gradually increased to 24 cmH₂O and the tidal volume was decreased to 350 ml. The lung sounds were heard equally in both lungs without wheezing. Ventolin was administered for bronchodilation, and rocuronium (10 mg) was injected intravenously for muscle relaxation; however, they produced almost no effect. There was no kinking or biting of the tube in the mouth, but the suction catheter could not pass beyond approximately 10 cm from the tube connector. We found that the pressure-volume loop and flow-volume loop showed obstructive patterns compared to the initial ones (Fig. 1A). In addition, ETCO₂ and PIP increased to 48 mmHg and 30 cmH₂O (preset pressure limit), respectively; the SpO₂ level was maintained at 99%. The fiberoptic bronchoscope was inserted, but we could not advance it past 10 cm; we found that the swelling of the internal wall of the tube was obstructing the lumen of the tube (Fig. 2A). We immediately replaced the ETT with a new one after the patient was placed in a supine position. Subsequently, the PIP was reduced to 15 cmH₂O and all other parameters normalized rapidly (Fig. 1B). The surgery was successful. The patient did not have any symptoms related to barotrauma and recovered well without complications.

**DISCUSSION**

Endotracheal intubation is the gold standard for airway...

management because it can establish a definitive airway, provide maximal protection against the aspiration of gastric contents, and allow positive pressure ventilation [2]. Furthermore, high concentrations of oxygen, other gases, or volatile anesthetics, as well as some medications, can be administered to patients via ETT [3]. However, laryngoscopy and endotracheal intubation are associated with complications such as hypoxia, hypercarbia, dental and airway trauma, tube malpositioning, physiological responses to airway instrumentation, or tube malfunction [4]. These complications can occur during airway management, including during laryngoscopy and intubation, while the tube is in place, or following extubation. Kinking or biting of the tube, thick or inspissated mucus, or blood in the lumen can lead to obstruction of the ETT, which may cause ventilatory failure, and such an occurrence is sometimes observed. Valve or cuff damage also results in ETT malfunction; their integrity should be verified prior to use. Furthermore, polyvinyl chloride tubes may be ignited by cautery or laser in an oxygen/nitrous oxide-enriched environment. Therefore, a patent airway is not guaranteed by only keeping ETT in place. Furthermore, the ETT itself may cause airway obstruction [5].

Armored ETTs are cuffed, wire-reinforced, silicone rubber tubes that are quite flexible but difficult to compress or kink. This can make them useful for fiberoptic intubation, intubation through a tracheostomy, head and neck cases, neurosurgical cases, and patients placed in the prone position [6]. However, intraoperative airway obstruction caused by malfunction of a reinforced ETT has been previously reported. It is relatively easy to identify tube obstruction caused by biting on the tube [7] or by kinking [8] that results in compression of the reinforcing coils, which leads to narrowing of the lumen irreversibly. It is more difficult to recognize tube obstruction from rare causes, such as dissection of the inner membrane of a reinforced ETT. Most of these cases were caused by exposure to heat during resterilization of the ETT [9-11], use of N₂O during anesthesia [10,12,13], damage to the inner wall because of stretching of the ETT [9], or forceful manipulation of the stylet. Choi et al. [14] reported dissection of the inner wall of a new reinforced ETT without any N₂O; however, there was unusual resistance during stylet insertion before use. In this case report, we used a newly unpacked reinforced ETT and did not stretch or press the ETT during intubation or patient positioning. We felt some resistance during the stylet manipulation, although it was not markedly more than usual; we also used N₂O after intubation. Because of the greater solubility of N₂O compared to N₂, either the volume (if distensible) or the pressure (if non-distensible) of the air-containing space is increased during exposure to N₂O [15]. Together with the use of N₂O and careless manipulation of the stylet, the possibility of a manufacturing error, in which tiny air bubbles are included in the wall [9,12,13], might have been the cause of the inner wall dissection.

In the prone position, ventilatory distress may be a serious complication [13]; if it was caused by the ETT, the problem would be more detrimental to the patient because of the difficulty in changing the tube rapidly. Fortunately, we detected the ETT obstruction and changed it before the skin incision was performed, which might have delayed the changing of the tube. The differential diagnosis for ventilatory distress included consideration of pneumothorax and bronchospasm. In this case, auscultation of both lungs remained possible; breath sounds were found to be normal, and Ventolin administration for bronchodilation was not effective. However, the changes in the pressure-volume loop, which shifted to the right and downward; changes in the flow-volume loop, with diminished expiratory flow; and failure to advance the suction catheter led us to conclude that there was a problem with the ETT. Furthermore, the fiberoptic bronchoscope allowed us to visualize the ETT lumen that was obstructed by the bulging inner wall; thus, we decide to change it. After the ETT was changed, the cross-sectioned ETT was found to have a dissected inner wall that bulged into the lumen (Fig. 2B).

In conclusion, intraoperative airway obstruction can result from rare causes, such as dissection of the internal wall of reinforced ETT. For patient safety, it is necessary to recognize the possibility of airway obstruction due to a rare cause and to monitor patients vigilantly when they are under anesthesia.
