Abstract: Using a renormalized linked-cluster-expansion method, we have extended to order $\beta^{23}$ the high-temperature series for the susceptibility $\chi$ and the second-moment correlation length $\xi$ of the spin-1/2 Ising models on the sc and the bcc lattices. A study of these expansions yields updated direct estimates of universal parameters, such as exponents and amplitude ratios, which characterize the critical behavior of $\chi$ and $\xi$. Our best estimates for the inverse critical temperatures are $\beta^c = 0.221654(1)$ and $\beta^{b_{cc}} = 0.157375(6)$. For the susceptibility exponent we get $\gamma = 1.2375(6)$ and for the correlation length exponent $\nu = 0.6302(4)$. The ratio of the critical amplitudes of $\chi$ above and below the critical temperature is estimated to be $C_+ / C_- = 4.762(8)$. The analogous ratio for $\xi$ is estimated to be $f_+ / f_- = 1.963(8)$. For the correction-to-scaling amplitude ratio we obtain $a_+^2 / a_-^2 = 0.87(6)$.

I. INTRODUCTION

As a part of an ongoing long-term program of computer-based calculations and analyses of HT series for two-dimensional and for three-dimensional lattice spin models, we have extended by two terms the high-temperature (HT) series for the spin-1/2 Ising model on the simple-cubic (sc) and the body-centered-cubic (bcc) lattices. In the first analysis presented here, we shall restrict to consider the HT expansions through $\beta^{23}$ for the susceptibility $\chi$ and the second-moment correlation length $\xi$, mainly in order to update the direct estimates of the corresponding critical indices $\gamma$ and $\nu$.

For the sc lattice, the longest expansions of these quantities already in the literature reach order $\beta^{21}$. They were obtained and analyzed in Ref. 1 only a few years ago. In the case of the bcc lattice, the published series for $\chi$ and $\xi$, also extending through $\beta^{21}$, were calculated by B.G. Nickel two decades ago. The progress in such computations has been slow due to the exponential growth of their complexity with the order of the expansion so that even adding only a few terms to the present results is a laborious task. Within the renormalized linked-cluster-expansion method, used in our work, one must overcome many problems of combinatorial nature concerning graph generation, classification and partial resummation, and a special effort must be devoted to keep under strict control the numerous possible sources of error. In our case, a final severe test is provided by having the program to reproduce, in three dimensions, established data like the series for the nearest-neighbor spin correlation on the sc lattice, which is already tabulated through $\beta^{27}$, and in two dimensions, the series for $\chi$ and $\mu_2$ on the simple square lattice, which are known through $\beta^{35}$ and beyond. After the completion of this work, a preprint has been issued which also reports independently extended expansions for $\chi$ and $\mu_2$ on both the the sc and the bcc lattice through orders $\beta^{21}$ and $\beta^{35}$ respectively. Our series coefficients agree with those of Ref. 1 as far as the expansions overlap. This adds further confidence about the correctness of the results since our implementation of the linked cluster expansion procedure is rather different from that described in Ref. 1.

Any enrichment of the exact informations on the 3d Ising model is still of general interest. Here we have used these novel data to improve the knowledge of the nonnegligible singular corrections to the leading critical singularities of $\chi$ and $\xi$ and, as a consequence, the accuracy of the direct HT series estimates of all critical parameters. As stressed in Ref. 1, the corrections to scaling first showed up unambiguously when the bcc series were extended to order $\beta^{21}$, the last three coefficients being crucial. It is therefore helpful to produce more coefficients, in order to stabilize and possibly refine the quality of the information extracted from the series.

The plan of this note is as follows: after setting our notational conventions in Sec. II, we tabulate the series coefficients for $\chi$ and $\mu_2$ through order 23, with respect to the usual HT expansion variable $v = \theta(\beta)$. In Sec. III we report the results of our extrapolations for the critical temperatures, for the critical exponents $\gamma$ and $\nu$, for the universal ratio $C_+ / C_-$ of the critical amplitudes of the susceptibility above and below the critical point, for
the analogous ratio $f_+/f_-$ of the correlation-length amplitudes and for the ratio $a_2^+ / a_2^-$ of the correction-to-scaling amplitudes. Our estimates are compared with the latest numerical calculations by series, by stochastic methods and by perturbative renormalization group (RG) techniques, in the fixed-dimension (FD) approach and in the $c$-expansion approach. Less recent studies have been already reviewed in our Refs.

II. DEFINITIONS AND NOTATIONS

In order to introduce our notation, we shall specify by the Hamiltonian

$$H[s] = -\frac{J}{2} \sum_{\langle \vec{x}, \vec{x}' \rangle} s(\vec{x})s(\vec{x}')$$

(1)

the nearest-neighbor three-dimensional spin-1/2 Ising model in zero magnetic field. Here $s(\vec{x}) = \pm 1$ is the spin variable at the lattice site $\vec{x}$, and the sum extends over all nearest neighbor pairs of sites. We shall consider expansions in the usual HT variable $\beta = J/k_B T$ called “inverse temperature” for brevity. However, for convenience, we shall tabulate the series coefficients with respect to the expansion variable $v = th(\beta)$.

The susceptibility is expressed in terms of the connected two-spin correlation function $\langle s(\vec{x})s(\vec{y}) \rangle_c$ by

$$\chi(\beta) = \sum_{\vec{x}} \langle s(0)s(\vec{x}) \rangle_c = 1 + \sum_{r=1}^{\infty} a_r \beta^r;$$

(2)

and the second moment of the correlation function is defined as

$$\mu_2(\beta) = \sum_{\vec{x}} \vec{x}^2 \langle s(0)s(\vec{x}) \rangle_c = \sum_{r=1}^{\infty} b_r \beta^r.$$

(3)

In terms of $\chi$ and $\mu_2$ the second-moment correlation length $\xi$ is defined by

$$\xi^2(\beta) = \frac{\mu_2(\beta)}{6\chi(\beta)}.$$  

(4)

For easy reference we report here the complete expansions of $\chi$ and $\mu_2$, rather than only the lastly computed two coefficients. For the susceptibility on the sc lattice we have

$$\chi^{sc}(v) = 1 + 6v + 30v^2 + 150v^3 + 726v^4 + 3510v^5 + 16710v^6 + 79494v^7 + 375174v^8 + 1769686v^9 + 8306862v^{10}$$

$$+38975286v^{11} + 182265822v^{12} + 852063558v^{13} + 3973784886v^{14} + 18527532310v^{15} + 8622866794v^{16}$$

$$+4012253680v^{17} + 1864308847838v^{18} + 8660961643254v^{19} + 40190947325670v^{20} + 186475198518726v^{21}$$

$$+864404776466406v^{22} + 4006394107568934v^{23} + \ldots$$

for the second moment on the sc lattice:

$$\mu_2^{sc}(v) = 6v + 72v^2 + 582v^3 + 4032v^4 + 25542v^5 + 153000v^6 + 880422v^7 + 4920576v^8 + 26879670v^9 + 144230088v^{10}$$

$$+762587910v^{11} + 3983525952v^{12} + 20595680694v^{13} + 105558845736v^{14} + 536926539990v^{15} + 271314804256v^{16}$$

$$+13630071574614v^{17} + 6812177934520v^{18} + 338895833104998v^{19} + 1678998083744448v^{20} + 82871364767862v^{21}$$

$$+40764741656730408v^{22} + 199901334823355526v^{23} + \ldots$$

for the susceptibility on the bcc lattice:

$$\chi^{bcc}(v) = 1 + 8v + 56v^2 + 392v^3 + 2648v^4 + 17864v^5 + 118760v^6 + 789032v^7 + 5201048v^8 + 34268104v^9 + 224679864v^{10}$$

$$+112340878432v^{11} + 673345306832v^{12} + 4040430292128v^{13} + 25262619881120v^{14} + 161557405566080v^{15}$$

$$+969344633392000v^{16} + 5816067760144000v^{17} + 35358406560896000v^{18} + 218150437765452800v^{19}$$

$$+1308902666598780800v^{20} + 7853415999552992000v^{21} + 47120505597318579200v^{22} + 28272303358231398400v^{23} + \ldots$$

for the second moment on the bcc lattice:

$$\mu_2^{bcc}(v) = 6v + 72v^2 + 582v^3 + 4032v^4 + 25542v^5 + 153000v^6 + 880422v^7 + 4920576v^8 + 26879670v^9 + 144230088v^{10}$$

$$+762587910v^{11} + 3983525952v^{12} + 20595680694v^{13} + 105558845736v^{14} + 536926539990v^{15} + 271314804256v^{16}$$

$$+13630071574614v^{17} + 6812177934520v^{18} + 338895833104998v^{19} + 1678998083744448v^{20} + 82871364767862v^{21}$$

$$+40764741656730408v^{22} + 199901334823355526v^{23} + \ldots$$

III. ANALYSIS OF THE SERIES

In terms of the reduced inverse temperature \( \tau^# = 1 - \beta/\beta^c \), the asymptotic critical behavior of the susceptibility is expected to be

\[
\chi^#(\beta) \simeq C_+^#(\tau^#)^{-\gamma} \left( 1 + a^+\chi^#(\tau^#)^\theta + \ldots + e^+\chi^# \tau^# + \ldots \right)
\]  

(5)
as the critical point \( \beta^#_c \) is approached from below. (Here and in what follows, the superscript # stands for either sc or bcc, as appropriate, and will be dropped whenever unnecessary. The index +(−) denotes, as usual, quantities associated with the high (low) temperature side of the critical point.) Similarly, for the correlation length \( \xi \), we expect

\[
\xi^#(\beta) \simeq f_+^#(\tau^#)^{-\nu} \left( 1 + a^+\xi^#(\tau^#)^\theta + \ldots + e^+\xi^# \tau^# + \ldots \right)
\]  

(6)
as \( \tau \to 0^+ \).

The exponents \( \gamma, \nu, \) and \( \theta \) are universal quantities, whereas the critical amplitudes \( C^#, f^#, \) the amplitudes \( a^\chi^#, \) \( a^\xi^# \) of the leading nonanalytic correction-to-scaling terms and the amplitudes \( e^\chi^#, e^\xi^# \) of the leading analytic corrections are nonuniversal, as suggested by the superscript #. Experimentally accessible universal combinations can be formed out of the critical amplitudes[23]. Here we shall be concerned with series estimates of the universal ratios \( C_+^c/C_-, f_+^c/f_- \) and \( a^\chi^c/a^\xi^c \). Notice that for the critical amplitudes we have adopted the notation of Ref[23] and of other recent studies rather than that of Ref[23].

A. Estimates of the critical points

As a first step of the analysis, we shall examine the series for the susceptibility whose coefficients have the smoothest pattern of behavior, so that they are generally used to estimate the critical temperatures. These estimates will also be used to bias the determination of the critical exponents and of the universal amplitude ratios, therefore their accuracy is crucial. Let us begin by considering the results obtained by a very efficient variant of the ratio method introduced by J. Zinn-Justin[23] (see also[24]).

We evaluate \( \beta^c \) from the sequence

\[
(\beta^c)_n = (a_{n-2}a_{n-3}/a_{n}a_{n-1})^{1/4} \exp[\frac{s_n + s_n - 2}{2s_n(s_n - s_n - 2)}] = \beta^c + O(\frac{1}{n^{1+\#}})
\]  

(7)

where

\[
s_n = \left( \ln(\frac{a_{n-2}^2}{a_n a_{n-4}})^{-1} + \ln(\frac{a_{n-3}^2}{a_{n-1} a_{n-5}})^{-1} \right)/2
\]  

(8)
This is an unbiased method, in the sense that no additional accurate information must be used together with the series in order to get the estimates of the critical parameters, but we found useful to improve the procedure by biasing it with the value of \( \theta \) as follows. For sufficiently large \( n \), the sequence of estimates \( (\beta_c)_n \) shows very small regular oscillations due to the loose structure of the lattice. Moreover the odd and even subsequences of \( (\beta_c)_n \) have a residual decreasing trend which is very nearly linear on a \( 1/n^{1+\theta} \) plot, as suggested by eq. (7). Therefore, simply taking the highest order term of the sequence \( (\beta_c)_n \) as the final estimate, would be an inadequate choice. We have preferred to extrapolate separately to \( n \to \infty \) the successive odd and even pairs of estimates \( (\beta_c)_n \), assuming that we know the value of \( \theta \) well enough. The two sequences of extrapolated values need further extrapolation which allows also for the small residual curvature of the plot and leads to the final estimates \( \beta_c^{cc} = 0.221654(1) \), in the case of the sc lattice, and \( \beta_c^{bcc} = 0.1573725(6) \), in the case of the bcc lattice. The errors we have reported, account generously both for the present uncertainty in \( \theta \) (whose effects in this analysis are very small anyway) and for the uncertainty of the second extrapolation. For the correction-to-scaling exponent we have assumed the value \( \theta = 0.504(8) \), obtained by the FD perturbative RG.

Also in the rest of this note the central values of all \( \theta \)-biased estimates will refer to this value. However, in the calculations of this and the next subsection, we have also considered a much larger uncertainty, in order to make sure that our results are compatible with somewhat higher central values such as \( \theta = 0.52(3) \), proposed in Ref. [22] (as well as in Ref. [23] with a smaller error), or with \( \theta = 0.53(1) \) suggested in Ref. [24]. An even larger central value \( \theta = 0.54(3) \) was indicated in Ref. [25] while an experimental measure reported in Ref. [26] yields \( \theta = 0.57(9) \). In the case of the bcc lattice, as an example of our extrapolation procedure, we have reported in Table 1 the last eight terms of the sequence \( (\beta_c)_n \) and the results of the initial extrapolation of the last six successive alternate pairs of terms. Our final result for the critical inverse temperature of the Ising model on the sc lattice is completely compatible, although much less precise than the value \( \beta_c^{cc} = 0.22165459(10) \) obtained from an extensive Monte Carlo (MC) study by a dedicated Cluster Processor [27] and generally considered as the best available estimate. Our central value of \( \beta_c^{bcc} \), obtained similarly, is only slightly smaller, but more precise than the value \( \beta_c^{bcc} = 0.157373(2) \) suggested in Nickel and Rehr analysis [28]. We should finally mention that Prof. D. Stauffer kindly informed us that he still tends to favor the somewhat larger central estimate \( \beta_c^{cc} = 0.221659 \), basing on the HT analysis in Ref. [29], as well as on his own recent simulation of the critical dynamics and on analogous work in Ref. [30]. We also recall that a similar value \( \beta_c^{cc} = 0.2216595(26) \) was indicated a decade ago in the Monte Carlo simulation of Ref. [30]. In the context of our analysis, these values lie approximately halfway between the highest order approximant \( (\beta_c^{cc})_{23} \approx 0.221667 \) and our final estimate obtained from extrapolation. To close this section, three remarks are in order. First: the reliability of our analysis procedure has been corroborated by repeating it with the recently computed \( O(\beta_{26}) \) series for the self-avoiding-walk (saw) model on the sc lattice [31]. This is a relevant test because the structure of the corrections to scaling (namely the sign and size of the correction amplitude and the value of the confluent exponent \( \xi \)) is expected to be quite similar to the Ising sc case. For the saw model we have observed that the central value for \( \beta_s \) indicated by our procedure is essentially stabilized after reaching the order \( \beta_{23} \) and agrees closely with that indicated in Ref [31], while the error decreases as higher order coefficients are included in the analysis. Our procedure has also been tested and confirmed by other arguments in Ref. [31]. Second: due to the higher coordination number of the bcc lattice, the corresponding series have a greater “effective length” than the sc series, and therefore all estimates obtained for the bcc lattice will be systematically more accurate. Third: as expected, the inclusion in our analysis of the two additional coefficients for the expansion of \( \chi \) on the bcc lattice, computed in Ref. [32], does not essentially modify our central estimate of \( \beta_{c}^{bcc} \), but only reduces its uncertainty to the value reported here.

### B. Estimates of the critical exponents

By using a related variant of the ratio method and by analogous arguments, fairly good estimates can be obtained also for the exponents \( \gamma \) and \( \nu \). We construct the approximation sequence

\[
\gamma_n = 1 + \frac{2(s_n + s_{n-2})}{(s_n - s_{n-2})^2} = \gamma + \mathcal{O}\left(\frac{1}{n^\theta}\right)
\]

with the same definition as above for \( s_n \). Also in this case, for sufficiently large \( n \), the successive estimates \( \gamma_n \), (as well as the analogous ones \( \nu_n \) obtained from the series coefficients of \( \xi^2 \)), appear to be nearly linear on a \( 1/n^\theta \) plot, and therefore we can follow an extrapolation procedure completely analogous to the one previously described. However, in the exponent calculation, the corrections are a priori larger and therefore the procedure involves relative errors larger than in the case of \( \beta_c \). In order to illustrate this numerical procedure in the case of the bcc lattice, we have reported in Table 1 the last eight terms of the sequence \( \gamma_n \) and the results of the extrapolation of the last six successive alternate pairs of terms. The estimates inferred from the analysis of these data are: \( \gamma = 1.2378(10) \) and \( \nu = 0.629(2) \) in the case of the sc series and \( \gamma = 1.2373(6) \) \( \nu = 0.629(1) \) from the bcc series. As expected, the
relative uncertainties for the exponent $\nu$ are larger because of the slower approach of the second moment series to its asymptotic behavior. The dependence of these estimates on the value of $\theta$ used in the extrapolation can be expressed as follows: $\gamma = 1.2378 + 0.016(\theta - 0.504) \pm 0.0010$ and $\nu = 0.629 + 0.02(\theta - 0.504) \pm 0.0020$ in the case of the sc lattice; $\gamma = 1.2373 + 0.012(\theta - 0.504) \pm 0.0006$ and $\nu = 0.629 + 0.016(\theta - 0.504) \pm 0.0010$ in the case of the bcc lattice.

In order to confirm these estimates for the exponents, we shall resort also to (unbiased and biased) analyses by inhomogeneous differential approximants (DA’s). By unbiased DA’s, we obtain somewhat larger estimates both for the critical inverse temperatures and for the exponents, which, however, show a clear decreasing trend. Therefore also these data should be further extrapolated, but, unfortunately, this is not as straightforward as in the case of the Zinn-Justin method. Thus we did not insist on this route and preferred to perform biased series analyses, either i) by the first-order simplified differential approximants (SDA) introduced and discussed in Ref.\cite{39} in which both $\beta_c$ and the correction-to-scaling exponent $\theta$ are fixed, or alternatively ii) by conventional second order inhomogeneous DA’s, in which $\theta$ and $\beta_c$ are varied in a small neighbourhood of their expected values, following the method of Ref.\cite{38}. Let us also add that in all cases in which we have relied on SDA’s, we have also repeated the same calculation, first subjecting the series to the biased variable change introduced by R. Roskies\cite{37} in order to regularize the leading correction to scaling and then computing simple Padé approximants. In this way we have always obtained completely consistent results, although they are sometimes affected by larger uncertainties.

We have used the procedure i) to study the residue of the log-derivative of $\chi$ or of $\xi^2$ at the critical singularity. In the case of the sc lattice series, rather than our own estimate of $\beta_c$, we have used the more accurate (but otherwise completely consistent) value $\beta_c^{sc} = 0.22165459(10)$ of Ref.\cite{23}. Thus we estimate $\gamma = 1.2378(10)$ and $\nu = 0.6306(8)$.

In the analysis of the bcc lattice series, we have taken as a bias the value suggested by our extended ratio-method analysis $\beta_c^{bcc} = 0.1573725(6)$. In this case we get the values $\gamma = 1.2375(6)$ and $\nu = 0.6302(4)$. By using Fisher scaling law, we get $\eta = 0.037(3)$ from the sc series and $\eta = 0.036(2)$ from the bcc series. For both lattices we have used the same value (and uncertainty) of $\theta$ as previously discussed and we have easily allowed for the residual decreasing trend of the exponent estimates, because SDA’s values show a smaller spread than DA’s. We can also mention that in the bcc lattice case, the linearized dependence of the exponent central estimates on the bias values of $\beta_c$ and $\theta$ can be described as follows: $\gamma = 1.2375 + 0.01(\theta - 0.504) + 90.0(\beta_c - 0.1573725)$ and $\nu = 0.6302 + 0.015(\theta - 0.504) + 40.0(\beta_c - 0.1573725)$.

We shall take as our final estimates for the exponents those obtained by SDA’s from the bcc lattice, which are best converged.

The so-called M2 method of Ref.\cite{38} is a very useful extension of the above mentioned Roskies’ procedure. In the case of the bcc lattice it suggests $\beta_c^{bcc} = 0.1573720(4)$ with $\gamma = 1.2374(4)$ and $\theta = 0.56(3)$, in good consistency with the other approaches. On the other hand, in the case of the sc lattice, the results of the M2 method at order $\beta^{21}$, namely $\beta_c^{sc} = 0.221659(2)$ $\gamma = 1.2395(5)$ with $\theta = 0.50(2)$ are not essentially changed with respect to those obtained in Ref.\cite{37} from the analysis of our previous $O(\beta^{21})$ series.

In conclusion, provided that the sequences of estimates are carefully extrapolated using the independently computed value of $\theta$, the determination of the exponents by the improved ratio method and by biased DA’s or SDA’s are completely consistent, though the latter method gives slightly more accurate results. At this order of expansion, asymptotic trends seem to be already stabilized and the uncertainties in the HT series estimates are significantly reduced. A sample of recent estimates of the critical exponents is reported in Table 2 and briefly commented in the rest of this subsection. The agreement of our results with the values $\gamma = 1.2396(13)$ and $\nu = 0.6304(13)$, indicated by the FD perturbative RG\cite{41}, or the values $\gamma = 1.2380(50)$ and $\nu = 0.6305(25)$, suggested by the $\epsilon$-expansion\cite{42}, is still good. However, we should observe that, in the years, as the length of the HT series has increased, the exponent estimates have been moving towards the slightly lower central values $\gamma \approx 1.237$ and $\nu \approx 0.630$. Indeed very similar values had already been suggested some time ago by J.H. Chen, M. E. Fisher and B. G. Nickel\cite{43} who studied soft spin models of the Ising universality class, chosen so to have negligible amplitudes for the leading corrections to scaling. Within this approach, the analysis of HT series through order $\beta^{21}$ for the bcc lattice gave $\gamma = 1.237(2)$ and $\nu = 0.6300(15)$. A study\cite{44} of the HT series through $O(\beta^{20})$ for the sc lattice, along the same lines as in Ref.\cite{33}, indicates $\gamma = 1.237(4)$ and $\nu = 0.63002(23)$. Recently, this method was adapted also to MC simulations in Ref.\cite{44}, which reports $\gamma = 1.2372(17)$ and $\nu = 0.6303(6)$. Analogously in Ref.\cite{33} the estimates $\nu = 0.6296(7)$ and $\eta = 0.0358(9)$ are obtained, implying $\gamma = 1.2367(20)$. Even lower central estimates of the exponents, namely $\gamma = 1.2353(25)$ and $\nu = 0.6294(10)$ have been obtained in a MC simulation of the Ising model by a finite-size scaling analysis\cite{45} which allows for the corrections to scaling.

C. Estimates of universal amplitude ratios

By taking advantage also of the low-temperature expansion of $\chi$ on the sc lattice, extended in Ref.\cite{23} to order $u^{26}$, (here $u = \exp(-4\beta)$), and of the other series for the bcc lattice computed to order $u^{23}$ in Ref.\cite{23}, we can give a new
direct estimate of the universal ratio $C_+/C_-$. Using the low-temperature series for $\xi^2$, computed for the sc lattice in Ref.\textsuperscript{34}, through $u_{33}$, we can also compute the ratio $f_+^{sc}/f_-^{sc}$. These quantities have been repeatedly evaluated in recent years by various techniques, with increasing accuracy.

We have used first order SDA’s to compute $C_{\pm}^{\#} = \lim_{\tau \to \pm \infty} |\tau|^{\gamma_{\pm}}$. In the sc lattice case, by choosing $\beta^{sc}_{+} = 0.22165459$, $\gamma = 1.2375$ and $\theta = 0.5$, we obtain $C^{sc}_{+}/C^{sc}_{-} = 4.762(8)$. Here the uncertainty refers to the sharp bias values above indicated. In order to compare this result with others obtained by slightly different assumptions, the dependence of our estimate on the bias values $\gamma_b$ and $\theta_b$ for the critical and the correction exponents can be linearly approximated by $C^{sc}_{+}/C^{sc}_{-} = 4.762 + 0.06(1.2375 - \gamma_b) + 0.7(\theta_b - 0.5) \pm 0.008$. The ratio is insensitive to the choice of $\beta^{sc}_{+}$ within its quoted uncertainty. In the case of the bcc lattice, we have used the same bias values for $\gamma$ and $\theta$ together with $\beta^{bcc}_{+} = 0.1573725$, obtaining $C^{bcc}_{+}/C^{bcc}_{-} = 4.76(3)$. In this case the error (mainly coming from the uncertainty of $C^{bcc}_{+}$) is larger, but the result is completely consistent with the sc lattice estimate.

The experimental measurements of this ratio range between 4.3 and 5.2\textsuperscript{27,39} and are perfectly compatible with our estimates. Other recent numerical evaluations are summarized in Table 3. However some comments are helpful for understanding these results. The previous evaluations by M.E. Fisher and coll.\textsuperscript{23,39} used shorter series and bias values $\gamma = 1.2395$ and $\beta^{sc}_{+} = 0.221630$ somewhat different from ours, thus yielding the slightly larger value 4.95(15). The ratio $C_+/C_-$ can also be obtained from approximate parametric representations of the scaling equation of state.\textsuperscript{43,44} Here we quote only the most recent such estimate: 4.77(2).

The MC simulation of Ref.\textsuperscript{34} gave the somewhat larger value 5.18(35), while the more recent and higher precision study of Ref.\textsuperscript{45} yields 4.75(3) and the work of Ref.\textsuperscript{45} reports 4.72(11).

Within the $\epsilon$–expansion approach to the RG, the estimate 4.73(16) is obtained, while the FD expansion gives the result 4.79(10).\textsuperscript{46} The value 4.72(17) was obtained in Ref.\textsuperscript{46}.

In a similar way, we have computed $f_+^{sc}/f_-^{sc} = 1.963(8)$, assuming $\nu = 0.6302$. The quoted uncertainty allows also for the uncertainties in the estimates of $\nu$ and $\theta$. Other estimates appearing in the recent literature are summarized in Table 4. Our result compares well with the estimate 1.96(1) obtained in Ref.\textsuperscript{44} by shorter series as well as with the recent estimate 1.961(7) of Ref.\textsuperscript{45}. The MC estimate of Ref.\textsuperscript{34} was 2.06(1), whereas in Ref.\textsuperscript{46} the value 1.95(2) is reported. The latest $\epsilon$–expansion estimate\textsuperscript{44} is 1.91 (with no indication of error bars) and the FD estimate\textsuperscript{46} is 2.013(28). The recent experimental estimates of this ratio range between 1.9(2) and 2.0(4).

We believe that the close agreement between our series estimates and the latest determinations of these universal ratios is due to the careful allowance of the confluent corrections to scaling by SDA’s. Indeed, even using the longer series presently available, simple Padé approximants, notoriously inadequate to describe the singular corrections to scaling, suggest estimates sizably larger, while the conventional DA’s lead to a wider spread in the estimates. Further improvements of the direct series determination of these ratios should probably await for an extension of the low-temperature series.

By using only the HT extended series presented here, we can also reevaluate the universal ratio $a_+^\xi/a_-^\chi$. Let us recall that, as observed in Ref.\textsuperscript{14}, and argued in earlier studies,\textsuperscript{29} for the spin-1/2 Ising model on the sc, the bcc and the fcc lattices, the amplitudes of the leading correction-to-scaling terms have a negative sign, both for the susceptibility and the correlation length. The values of these amplitudes can be most simply determined, also in this case, by using the SDA’s above mentioned. Our estimate for the universal ratio between these amplitudes: $a_+^{sc}/a_-^{sc} = 0.95(15)$ from the sc lattice series, and $a_+^{bcc}/a_-^{bcc} = 0.87(6)$ from the bcc lattice series, improves the accuracy of our previous result obtained from the analysis of shorter series. These results have to be compared with the FD result $a_+^\xi/a_-^\chi = 0.65(5)$ obtained in Ref.\textsuperscript{44} and with the HT result $a_+^{bcc}/a_-^{bcc} \approx 0.85$ of Ref.\textsuperscript{44}.

IV. CONCLUSIONS

We have extended through order $\beta^{sc}_{+}$ the HT expansions of the susceptibility and of the second correlation moment for the spin-1/2 Ising model, on the sc and the bcc lattices. As a first application of our calculation, we have updated the direct HT estimates of universal critical parameters of the Ising model with some improvement over previous analyses in the agreement and in the agreement with the latest calculations by approximate RG methods and by various numerical methods.

ACKNOWLEDGMENTS

This work has been partially supported by MURST. We thank Prof. A. Guttmann for his interest in our work and for making available to us Ref.\textsuperscript{14} before publication. We also thank Profs. L.N.Shchur, D. Stauffer and E. Vicari for their kind comments on the first version of this paper.
