Abstract. Copying, or cloning, is a basic operation used in the specification of many applications in computer science. However, when dealing with complex structures, like graphs, cloning is not a straightforward operation since a copy of a single vertex may involve (implicitly) copying many edges. Therefore, most graph transformation approaches forbid the possibility of cloning. We tackle this problem by providing a framework for graph transformations with cloning. We use attributed graphs and allow rules to change attributes. These two features (cloning/changing attributes) together give rise to a powerful formal specification approach. In order to handle different kinds of graphs and attributes, we first define the notion of attributed structures in an abstract way. Then we generalise the sesqui-pushout approach of graph transformation in the proposed general framework and give appropriate conditions under which attributed structures can be transformed. Finally, we instantiate our general framework with different examples, showing that many structures can be handled and that the proposed framework allows one to specify complex operations in a natural way.

1 Introduction

Graph structures and graph transformation have been successfully used as foundational concepts of modelling languages in a wide range of areas related to software engineering. Such a success mainly stems from the intuitive and pictorial features of graphs which ease the writing as well as the understanding of specifications. Several ways to define graph transformation rules have been proposed (see e.g., [21][11][13] for a survey). We can distinguish two main approaches: The algorithmic approach which is rather pragmatic and defines graph transformation rules by means of the algorithms used to transform the graphs (e.g. [3]) and the algebraic approach which is more abstract (e.g. [14]). This latter borrows notions from category theory to define graph transformation rules. The most popular algebraic approaches are the double pushout (DPO) [14][7] and the single pushout (SPO) [12].

* This work has been partly funded by the project CLIMT of the French Agence Nationale de la Recherche (ANR-11-BS02-016) and by the project TGV of CNRS-INRIA-FAP’s (# 156779).
Very often, graph structures are endowed with attributes. Such attributes, which enrich nodes and edges with data values, have been proven very useful to enhance the expressiveness of visual modelling frameworks (see, e.g., UML diagrams). These attributes can be simple names of an alphabet (labels) or elaborated expressions of a given language. Several investigations tackling attributed graph transformations have been proposed in the literature, see e.g. [18,17,10,19,15]. These proposals follow the so-called double pushout approach to define graph transformation steps. This approach can be used in many applications (see e.g. [7]) but it forbids actions which consist in cloning nodes together with their incident edges (merging of nodes is also usually forbidden). Moreover, this approach also prevents the application of rules that erase a node when there are edges connected to this node in the graph that represents the state (erasing nodes is only possible if all connected arcs are explicitly deleted by the rule).

However, there are applications in which these restrictions of DPO would lead to rather complex specifications. For instance, duplicating or erasing some component may be very useful in the development process of an architecture, and should be a simple operation. Also, making a security copy of a virtual machine in a cloud (for fault-tolerance reasons) is a very reasonable operation, as well as switching down a (physical) machine from the infrastructure of a cloud. To model such situations we may profit from cloning/merging as basic operations in a formalism. But we certainly need to use attributed structures to get a suitable formalism for real applications. In this paper, we propose a framework that has both the ability to model cloning/merging of entities in a natural way, and also the feature of using attributes together with the graphs.

To develop our proposal, we follow a more recent approach of graph transformation known as the sesqui-pushout approach (SqPO) [6]. This latter is a conservative extension of DPO with some additional features such as deletion or cloning.

A rule is defined, as in the DPO approach, by means of a span of the form $(l : L \leftarrow K \rightarrow R : r)$ where the morphisms $l$ and $r$ are not necessarily monos. The fact that $l$ is not mono allows one to duplicate some nodes and edges. Notice that most proposals dealing with attributed graphs assume $l$ to be mono. A rewrite step can be depicted as follows where the left square is a final pullback complement and the right square is a pushout. The intuition is analogous to the DPO approach: the left square specifies what is removed (and also what is cloned) by the rule application and the right square creates the new items. The difference, besides allowing non injective rules, is that when applying the rule the so called dangling condition does not need to be checked: if there are edges in $G$ connected to nodes in the image of $m$ that is deleted by the rule, these edges are automatically removed by the rule application. In DPO, in such a situation a rule would not be applicable.

\[
\begin{array}{ccc}
L & \xleftarrow{l} & K \xrightarrow{r} R \\
\downarrow m & \downarrow d & \downarrow h \\
G & \xleftarrow{l_1} & D \xrightarrow{r_1} H
\end{array}
\]

Sesqui-pushout: $G \xrightarrow{\text{sqpo}} H$
In order to consider different kinds of graphs and attributes, we present our approach in a general setting. That is to say, we consider structures of the form \( \hat{G} = (G, A, \alpha) \) made of an object \( G \) whose elements may be attributed, an object \( A \) defining attributes and a partial function \( \alpha \) which assigns to some elements of \( G \) attributes in \( A \). The fact that \( \alpha \) is partial turns out to be very useful to write transformation rules that change the attributes of some elements of \( G \) (see, e.g. [16,4]). We do not assume \( G \) to be necessarily a graph nor do we assume \( A \) to be necessarily an algebra. We thus elaborate a framework which can be instantiated with different kinds of structures and attributes fulfilling some criteria we introduce in this paper. Therefore we can handle different graphs with various kinds of attributes (algebras, lambda-terms, finite labels, syntactic theories, etc.). Similar objectives, with different outcome, have been recently investigated in [15] for the DPO approach.

The rest of the paper is organized as follows. The next section introduces the category of attributed structures and provides some definitions which may help the understanding of the paper. Section 3 recalls briefly the useful definitions regarding the sesqui-pushout approach. Then, Section 4 shows how to lift SqPO rewriting in the context of attributed structures. Sections 5 and 6 illustrate our approach through some examples while related work are discussed in Section 7. Concluding remarks are given in Section 8. The missing proofs may be found in the Appendix.

2 Attributed Structures

In this section we define the notion of attributed structures and set some notations.

**Structures.** Let \( G \) be a category and \( S : G \to \text{Set} \) a functor from \( G \) to the category of sets. For instance, \( G \) may be the category of graphs \( \text{Gr} \) [21] and \( S \) may be either the vertex functor \( V \) defined by \( V(G) = V_G \) and \( V(g) = g_V \), or the edge functor \( E \) defined by \( E(G) = E_G \) and \( E(g) = g_E \), or the functor \( V + E \) which maps each graph \( G \) to the disjoint union \( V_G + E_G \) and each morphism \( g : G_1 \to G_2 \) to the map \( g_V + g_E \).

**Attributes.** Let \( A \) be a category and \( T : A \to \text{Set} \) a functor from \( A \) to the category of sets. For instance, \( A \) may be the category \( \text{Alg}(\Sigma) \) of \( \Sigma \)-algebras [22] for some signature \( \Sigma = (S, \Omega) \), or more generally the category \( \text{Mod}(Sp) \) of models of an equational specification \( Sp = (\Sigma, E) \), made of a signature \( \Sigma \) and a set of equations \( E \). Then the functor \( T : A \to \text{Set} \) may be such that \( T(A) = \sum_{s \in S} A_s \), i.e., \( T \) maps each \( \Sigma \)-algebra \( A \) to the disjoint union of its carriers, or more generally \( T(A) = \sum_{s \in S'} A_s \) for some fixed subset \( S' \) of \( S \).

In the following, we sometimes write \( Fx \) instead of \( F(x) \) when a functor \( F \) is applied to an object or a morphism \( x \).

**Definition 1.** The category of attributed structures \( \text{AttG} \) (with respect to the functors \( S \) and \( T \)) is the comma category \((S \downarrow T)\). Thus, an attributed structure is a triple \( \hat{G} = (G, A, \alpha) \) made of an object \( G \) in \( G \), an object \( A \) in \( A \) and a map \( \alpha : S(G) \to T(A) \) (in \( \text{Set} \) ); and a morphism of attributed structures

\[
\hat{g} : (G, A, \alpha) \to (G', A', \alpha') \quad \text{is a pair \( g : G \to G' \) and \( \alpha' \circ S(g) = T(g) \circ \alpha \).}
\]
\[ \widehat{g} : \widehat{G} \to \widehat{G}', \text{ where } \widehat{G} = (G, A, \alpha) \text{ and } \widehat{G}' = (G', A', \alpha'), \text{ is a pair } \widehat{g} = (g, a) \text{ made of a morphism } g : G \to G' \text{ in } \mathbf{G} \text{ and a morphism } a : A \to A' \text{ in } \mathbf{A} \text{ such that } \alpha' \circ Sg = Ta \circ \alpha \text{ (in } \mathbf{Set}). \]

\[
\begin{array}{ccc}
\widehat{G} & \xrightarrow{\widehat{g}} & \widehat{G}' \\
\downarrow & & \downarrow \\
G & \xrightarrow{g} & G'
\end{array}
\]

\[
\begin{array}{ccc}
SG & \xrightarrow{\alpha} & TA \\
\downarrow & & \downarrow \alpha \\
Sg & = & Ta \\
\downarrow & & \downarrow \\
SG' & \xrightarrow{\alpha'} & T'A'
\end{array}
\]

**Partial maps.** Let \( \mathbf{Part} \) be the category of sets with partial maps, which contains \( \mathbf{Set} \). A partial map \( f \) from \( X \) to \( Y \) is denoted \( f : X \rightharpoonup Y \) and its domain of definition is denoted \( \mathcal{D}(f) \). The partial order between partial maps is denoted \( \leq \), it endows \( \mathbf{Part} \) with a structure of 2-category. By composing \( S \) and \( T \) with the inclusion of \( \mathbf{Set} \) in \( \mathbf{Part} \) we get two functors \( S_p : \mathbf{G} \to \mathbf{Part} \) and \( T_p : \mathbf{A} \to \mathbf{Part} \).

**Definition 2.** The category of partially attributed structures \( \mathbf{PAttG} \) (with respect to the functors \( S \) and \( T \)) is defined as follows. A partially attributed structure is a triple \( \widehat{G} = (G, A, \alpha) \) made of an object \( G \) in \( \mathbf{G} \), an object \( A \) in \( \mathbf{A} \) and a partial map \( \alpha : S_p(G) \to T_p(A) \) (in \( \mathbf{Part} \) ; and a morphism of partially attributed structures \( \widehat{g} : \widehat{G} \to \widehat{G}' \), where \( \widehat{G} = (G, A, \alpha) \) and \( \widehat{G}' = (G', A', \alpha') \), is a pair \( \widehat{g} = (g, a) \) made of a morphism \( g : G \to G' \) in \( \mathbf{G} \) and a morphism \( a : A \to A' \) in \( \mathbf{A} \) such that \( \alpha' \circ Sg \geq T_p a \circ \alpha \) (in \( \mathbf{Part} \)).

\[
\begin{array}{ccc}
\widehat{G} & \xrightarrow{\widehat{g}} & \widehat{G}' \\
\downarrow & & \downarrow \\
G & \xrightarrow{g} & G'
\end{array}
\]

\[
\begin{array}{ccc}
SG & \xrightarrow{\alpha} & TA \\
\downarrow & & \downarrow \alpha \\
S_p G & \geq & T_p A \\
\downarrow & & \downarrow \\
S_p G' & \xrightarrow{\alpha'} & T_p A'
\end{array}
\]

Such a morphism of partially attributed structures is called strict when \( \alpha' \circ S_p(g) = T_p(a) \circ \alpha \).

**Remark 1.** Clearly, \( \mathbf{AttG} \) is a full subcategory of \( \mathbf{PAttG} \) and every morphism in \( \mathbf{AttG} \) is a strict morphism in \( \mathbf{PAttG} \). The subcategory \( \mathbf{AttG} \) of \( \mathbf{PAttG} \) is called the subcategory of totally attributed structures.

**Definition 3.** A morphism of (partially) attributed structure \( \widehat{g} : \widehat{G} \to \widehat{G}' \) preserves attributes if \( \widehat{G} = (G, A, \alpha), \widehat{G}' = (G', A, \alpha') \) and \( \widehat{g} = (g, id_A) \) for some object \( A \) in \( \mathbf{A} \).

**Notations.** We will omit the subscript \( p \) in \( S_p \) and \( T_p \). Let \( (G, A, \alpha) \) be a (partially) attributed structure, the notation \( x : t \) means that \( x \in S(G), t \in T(A) \) and \( \alpha(x) = t \) (i.e., \( x \) has \( t \) as attribute), and the notation \( x : \perp \) means that \( x \in S(G), x \not\in \mathcal{D}(\alpha) \) (i.e., \( x \) has no attribute). Let \( (G, A, \alpha) \) and \( (G', A', \alpha') \) be attributed structures, let \( g : G \to G' \) in \( \mathbf{G} \) and \( a : A \to A' \) in \( \mathbf{A} \), then \( (g, a) : (G, A, \alpha) \to (G', A', \alpha') \) is a morphism of attributed structures if and only if for all \( x \in S(G) \) and \( t \in T(A) \) \( x : t \implies g(x) : a(t) \). Let
(G, A, α) and (G′, A′, α′) be partially attributed structures, let g : G → G′ in G and a : A → A′ in A, then (g, a) : (G, A, α) → (G′, A′, α′) is a morphism of partially attributed structures if and only if for all x ∈ SG and t ∈ TA x ∈ D(α) ⟹ g(x) ∈ D(α′) and then x : t ⟹ g(x) : α(t), and (g, a) is strict if and only if for all x ∈ SG and t ∈ TA x ∈ D(α) ⇐= g(x) ∈ D(α′), and then x : t ⟹ g(x) : α(t). The notation x : ⊥ can be misleading: of course we can extend a : TA → TA′ as a : TA + {⊥} → TA′ + {⊥} by setting a(⊥) = ⊥, but then it is false that x : t ⟹ g(x) : α(t) for each x ∈ SG and t ∈ TA + {⊥}. In fact, for each morphism of partially attributed structures (g, a) we have g(x) : ⊥ ⟹ x : ⊥, and it is only when g is strict that in addition x : ⊥ ⟹ g(x) : ⊥.

**Definition 4.** The **underlying structure functor** is the functor \( U_G : \text{PAttG} \rightarrow G \) which maps an attributed structure \((G, A, α)\) to the object \(G\) and \((g, a)\) to the morphism \(g\). The **underlying attributes functor** is the functor \( U_A : \text{PAttG} \rightarrow A \) which maps an attributed structure \((G, A, α)\) to the object \(A\) and \((g, a)\) to the morphism \(a\).

### 3 Sesqui-Pushouts

In this section we briefly recall the definition of sesqui-pushout (SqPO) rewriting, introduced in [6]. A sesqui-pushout rewriting step is made of a final pullback complement (FPBC) followed by a pushout (PO). The definitions of FPBC and SqPO are reminded here, in any category \(C\). The initiality property of POs and the finality property of FPBCs imply that POs, FPBCs and SqPOs are unique up to isomorphism, when they exist.

**Definition 5.** The **final pullback complement (FPBC)** of a morphism \(m_L : L \rightarrow G\) along a morphism \(l : K \rightarrow L\) is a pullback (PB) (below on the left) such that for each pullback (below on the right)

\[
\begin{array}{ccc}
L & \xleftarrow{l} & K \\
\downarrow{m_L} & & \downarrow{m_K} \\
G & \xleftarrow{l_1} & D
\end{array}
\]

\[
\begin{array}{ccc}
L & \xleftarrow{l'} & K' \\
\downarrow{m_L} & & \downarrow{m_K'} \\
G & \xleftarrow{l'_1} & D'
\end{array}
\]

and each morphism \(f : K' \rightarrow K\) such that \(l \circ f = l'\) there is a unique morphism \(f_1 : D' \rightarrow D\) such that \(l_1 \circ f_1 = l'_1\) and \(f_1 \circ m' = m_K \circ f_\).
Definition 6. The sesqui-pushout of a morphism \( m_L : L \to G \) along a span of morphisms \( (l : L \leftarrow K \to R : r) \) is the FPBC of \( m_L \) along \( l \) followed by the PO of \( m_K \) along \( r \) (see diagram below).

\[
\begin{array}{ccc}
L & \xrightarrow{l} & K & \xrightarrow{r} & R \\
\downarrow{m_L} & \xrightarrow{(FPBC)} & \downarrow{m_K} & \xrightarrow{(PO)} & \downarrow{m_R} \\
G & \xrightarrow{l_1} & D & \xrightarrow{r_1} & H
\end{array}
\]

A comparison of SqPO with DPO and SPO approaches can be found in [6], where it is stated that “Probably the most original and interesting feature of sesqui-pushout rewriting is the fact that it can be applied to non-left-linear rules as well, and in this case it models the cloning of structures.”

In the category of graphs, under the assumption that \( m_L : L \to G \) is an inclusion, the result of the sesqui-pushout can be described as follows [6, Section 4.1], [9]. With respect to a rule \( (l : L \leftarrow K \to R : r) \), let us call tri-node a triple \((n_L, n_K, n_R)\) where \( n_L, n_K \) and \( n_R \) are nodes in \( L, K \) and \( R \) respectively and where \( n_L = l(n_K) \) and \( n_R = r(n_K) \). Since \( m_L \) is an inclusion, \( L \) is a subgraph of \( G \). Let \( \mathcal{T} \) be the subgraph of \( G \) made of all the nodes outside \( L \) and all the vertices between these nodes. Let \( \hat{L} \) be the set of edges outside \( L \) with at least one endpoint in \( L \) (called the linking edges), so that \( G \) is the disjoint union of \( L, \mathcal{T} \) and \( \hat{L} \). Then, up to isomorphism, \( m_R \) is an inclusion and \( H \) is obtained from \( G \) by replacing \( L \) by \( R \) and by “gluing \( R \) and \( \mathcal{T} \) in \( H \) according to the way \( L \) and \( \mathcal{T} \) are glued in \( G \)”, which means precisely that \( H \) is the disjoint union of \( R, \mathcal{T} \) and the following set \( \hat{R} \) of linking edges (see [9] for more details):

- if \( n \) is a node in \( R \) and \( p \) a node in \( \mathcal{T} \), there is an edge from \( n \) to \( p \) in \( \hat{R} \) for each tri-node \((n_L, n_K, n_R)\) with \( n_R = n \) and each edge from \( n_L \) to \( p \) in \( \hat{L} \);
- if \( n \) is a node in \( \mathcal{T} \) and \( p \) a node in \( R \), there is an edge from \( n \) to \( p \) in \( \hat{R} \) for each tri-node \((p_L, p_K, p_R)\) with \( p_R = p \) and each edge from \( n \) to \( p_L \) in \( \hat{L} \);
- if \( n \) and \( p \) are nodes in \( R \), there is an edge from \( n \) to \( p \) in \( \hat{R} \) for each tri-node \((n_L, n_K, n_R)\) with \( n_R = n \), each tri-node \((p_L, p_K, p_R)\) with \( p_R = p \) and each edge from \( n_L \) to \( p_L \) in \( \hat{L} \).

4 Attributed Sesqui-Pushout Rewriting

In this section we define rewriting of attributed structures based on sesqui-pushouts, then we construct such SqPOs from SqPOs of the underlying (non-attributed) structures.

Definition 7. Given an object \( A \) of \( \mathbf{A} \), a rewriting rule with attributes in \( A \) is a span \((\hat{l} : \hat{L} \leftarrow \hat{K} \to \hat{R} : \hat{r})\), or simply \((\hat{l}, \hat{r})\), made of morphisms \( \hat{l} \) and \( \hat{r} \) in \( \mathbf{PAttG} \) which preserve attributes and such that \( \hat{L} \) and \( \hat{R} \) are totally attributed structures. A match for a rule \((\hat{l}, \hat{r})\) in an attributed structure \( \hat{G} \) is a morphism \( \hat{m} = (m, \alpha) : \hat{L} \to \hat{G} \) in \( \mathbf{AttG} \) such that the map \( \alpha m \) is injective. The SqPO rewriting step (or simply the rewriting step) applying a rule \((\hat{l}, \hat{r})\) to a match \( \hat{m} \) is the sesqui-pushout of \( \hat{m} \) along \((\hat{l}, \hat{r})\) in the category \( \mathbf{PAttG} \).
From the definition above, a rewrite rule is characterised by (i) the object $A$ of attributes, (ii) the attributed structures $\hat{L}$, $\hat{K}$, and $\hat{R}$ and (iii) the span of structures $(l : L \leftarrow K \rightarrow R : r)$. A match $\bar{m}$ must have an injective underlying morphism of structures but it may modify the attributes. In contrast, the morphisms $\hat{l} = (l, \text{id}_A)$ and $\hat{r} = (r, \text{id}_A)$ in a rule have arbitrary underlying morphisms of structures $l$ and $r$, thus allowing items to be added, deleted, merged or cloned, but they must preserve attributes since their underlying morphism on attributes is the identity $\text{id}_A$. However, since $\hat{K}$ is only partially attributed, any element $x \in SK$ without attribute may be mapped to $l(x) : a$ in $\hat{L}$ and to $r(x) : a'$ in $\hat{R}$ with $a \neq a'$. Thus the assignment of attributes to vertices/edges may change in the transformation process.

In the following when $(m, a)$ is a match we often assume that $Sm$ is an inclusion, rather than any injection; in this way the notations are simpler while the results are the same, since all constructions (PO, PB, FPBC) are up to isomorphism.

The construction of a sesqui-pushout in $\text{PAttG}$ can be made in two steps: first a sesqui-pushout in $G$, which depends only on the properties of the category $G$, then its lifting to $\text{PAttG}$, which does not depend any more on $G$. Moreover, this lifting is quite simple: since the morphisms $l$ and $r$ do not modify the attributes, it can be proved that $m_K$ and $m_R$ have the same underlying morphism on attributes as $m_L$. This is stated in Theorem 1.

**Theorem 1.** Let us assume that the functors $U_G : \text{PAttG} \rightarrow G$, $U_A : \text{PAttG} \rightarrow A$, $S : G \rightarrow \text{Set}$ and $T : A \rightarrow \text{Set}$ preserve PBs and that the functor $S$ preserves POs. Let $(l : L \leftarrow K \rightarrow R : r)$ be a rewriting rule and $\bar{m}_L = (m_L, a) : \hat{L} \rightarrow \hat{G}$ a match. If diagram $\Delta$ (below on the left) is a SqPO rewriting step in $G$ then diagram $\hat{\Delta}$ (below on the right) is a SqPO rewriting step in $\text{PAttG}$ and $(m_R, a)$ is a match.

\[
\begin{array}{ccc}
\Delta : & L & \rightarrow R \\
\downarrow m_L & \downarrow m_K & \downarrow m_R \\
G & \rightarrow & H \\
\end{array}
\]

\[
\hat{\Delta} : & \hat{L} & \rightarrow \hat{R} \\
\downarrow \hat{m}_L & \downarrow \hat{m}_K & \downarrow \hat{m}_R \\
\hat{G} & \rightarrow \hat{H} \\
\end{array}
\]

**Proof.** Since a sesqui-pushout is a FPBC followed by a PO, this proof relies on similar results about the lifting of FPBCs and the lifting of POs in Appendix A and B respectively.

Let us summarize what may occur for an element $x \in SD$. If $x \notin SK$ then only one case may occur:

\[
l_1(x) : t_1 \leftarrow x : t_1 \rightarrow r_1(x) : t_1
\]

If $x \in SK$ then two cases may occur:

\[
l(x) : t \leftarrow x : t \rightarrow r(x) : t \\
\downarrow \downarrow \downarrow \downarrow \\
l_1(x) : a(t) \leftarrow x : a(t) \rightarrow r_1(x) : a(t)
\]

\[
l(x) : t \leftarrow x : \bot \rightarrow r(x) : t' \\
\downarrow \downarrow \downarrow \downarrow \\
l_1(x) : a(t) \leftarrow x : \bot \rightarrow r_1(x) : a(t')
\]
5 Graph Transformations with Simply Typed $\lambda$-terms as Attributes

In this section we consider simply typed $\lambda$-terms as attributes. The choice of the $\lambda$-calculus can be motivated by the possibility to perform higher-order computations (functions can be passed as parameters). We refer to [2] for more details concerning the simply-typed $\lambda$-calculus, though basic notions of $\lambda$-calculus are enough to understand the example provided in this section.

First, let us choose the categories $\mathbf{G}$ and $\mathbf{A}$ and the functors $S$ and $T$. Let $\mathbf{G} = \mathbf{Gr}$ be the category of graphs. Let $S : \mathbf{G} \to \mathbf{Set}$ be the functor which maps each graph to the disjoint union of its set of vertices and its set of edges. We define the category $\mathbf{A}$ as the category where objects are sets $\Lambda(X)$ of simply typed $\lambda$-terms, à la Church, built over variables in $X$. For the sake of simplicity we only consider one base type $\iota$. Simply typed $\lambda$-terms in $\Lambda(X)$, noted $t$, and types, noted $\tau$, are defined inductively by: $\tau ::= \iota \mid \tau \to \tau$ and $t ::= x \mid (t \ t) \mid \lambda x^\tau.t$ with $x \in X$. A morphism $m$ from $\Lambda(X)$ to $\Lambda(X')$ is totally defined by a substitution from $X$ to $\Lambda(X')$. The functor $T : \mathbf{A} \to \mathbf{Set}$ is such that $T(\Lambda(X))$ is the set of normal forms of elements in $\Lambda(X)$. Other choices for $T$ are possible, for instance $T(\Lambda(X))$ could be chosen to be $\Lambda(X)$ itself. However in this case there would be no reduction in the attributes while rewriting. With the definitions as above, the functors $U_G : \mathbf{PAttG} \to \mathbf{Gr}$, $U_A : \mathbf{PAttG} \to \mathbf{A}$, $S : \mathbf{Gr} \to \mathbf{Set}$ and $T : \mathbf{A} \to \mathbf{Set}$ preserve pullbacks, and $S$ preserves pushouts.

Graph transformations can be coupled with $\lambda$-term evaluation. For instance, a vertex, $n$, of a right-hand side, $R$, of a rule may be attributed with a lambda-term, $t$, containing free variables which occur in the left-hand side $L$. A match, $\sigma$ of such a rule instantiates the free variables. Firing the rule will result in (i) the computation of the normal form of the lambda-term $\sigma(t)$ and (ii) its attribution to the image of vertex $n$ in the resulting transformed graph. Below we give an example of such a rule and illustrate it on the graph $\lambda G$.

$$
\begin{array}{c|c|c}
\lambda G & \lambda D & \lambda H \\
\hline
\begin{array}{c}
\underbrace{n:x} \\
\overbrace{p:f}
\end{array}
& \begin{array}{c}
\underbrace{m:\perp} \\
\overbrace{p:f}
\end{array}
& \begin{array}{c}
\underbrace{n:(f \ x \ y)} \\
\overbrace{m:y}
\end{array} \\
\begin{array}{c}
\underbrace{n:w} \\
\overbrace{p:\lambda s'.\lambda t'.s}
\end{array}
& \begin{array}{c}
\underbrace{m:\lambda u'.u} \\
\overbrace{p:\lambda s'.\lambda t'.s}
\end{array}
& \begin{array}{c}
\underbrace{n:w} \\
\overbrace{p:\lambda s'.\lambda t'.s}
\end{array} \\
\begin{array}{c}
\underbrace{m:\perp} \\
\overbrace{p:\lambda s'.\lambda t'.s}
\end{array}
& \begin{array}{c}

\end{array}
& \begin{array}{c}
\underbrace{m:\lambda u'.u} \\
\overbrace{p:\lambda s'.\lambda t'.s}
\end{array}
\end{array}
$$

Graph morphisms are represented via vertex name sharing, and $U_A$ can be deduced from them (for instance attribute $x$ in $L$ is instantiated by attribute $w$ in $\lambda G$ because of the match on vertex $n$, likewise $f$ is instantiated by $\lambda s'.\lambda t'.s$ and $y$ is instantiated by $\lambda u'.u$). In this example several features of our framework are underlined. First, notice that vertex $m$ in $L$ is cloned, as a structure, into
This cloning of structure implies that the edges incident to m in λG are to be duplicated for m and m′ in λH. As for attributes, the example shows that the structure can be cloned while the attributes can be changed (this is the case for the attribute of vertex m′). The edge between vertices n and p is erased since it is matched and is not present in K nor in R. Furthermore, the attribute of n in R shows a higher-order computation. Via the match, f is substituted by the function λs′.λt′.s and is applied to the instances of x and y. In λH the attribute of n is the normal form of (λs′.λt′.s w λu′.u) which is w. Attributes can be easily copied, e.g., f occurs twice in R. Finally, attributes of a vertex can be modified thanks to the partiality of the attribution in K. It is witnessed on vertices n and even m′ which is a clone of m. In fact m′ clones only the incident edges of m, one would have to write m′: y to copy the attribute of m as well.

Free variables are used to provide arguments of lambda-terms. This allows us to simulate the attribute dependency relation introduced in [5].

### 6 Graph Transformations with Attributes Defined Equationally: Administration of Cloud Infrastructure

In this section we explore how our framework allows us to take into account attributed graph transformations with attributes built over equational specifications. First we instantiate the definition with appropriate categories and functors, and then model an example.

Let the category G and functor S : G → Set be defined as in section [6]. Let T : A → Set be the functor which maps each model of Sp = (Σ, E), with Σ = (S, Ω), to the disjoint union of the carriers sets As for s in some given set of sorts S. With the definitions as above, the functors UG : PAttG → Gr, UA : PAttG → Mod(Sp), S : Gr → Set and T : Mod(Sp) → Set preserve pullbacks, and S preserves pushouts.

Cloud Computing is very popular nowadays [1]. The general idea is that there is a pool, called cloud, of resources (equipment, services, etc.) that may be requested by users. A user may, for example, request a machine with some specific configuration and services from the cloud. The cloud administrator chooses an actual physical machine that is available and installs on it a virtual machine (short VM) according to the user specification. The user does not have to know neither where this machine is nor how the services are implemented, communication with his machine is done via the cloud. The cloud administrator has many tasks to perform, besides communicating with the clients (users). Typical operations involve load balance among the machines, optimisation of the use of machines, etc. In the following we provide the specification using graph transformations of some operations of a cloud administrator. First we define the static structure, defining data types and the states of the system (as attributed graphs), and then we define the operations (as rules). Since the purpose of this case study is to show the use of our framework, we will not describe a complete set of attributes and rules needed to specify the behaviour of a cloud administrator, but concentrate on those parts that make explicit use of the features of the approach.
6.1 Cloud Administration: Static Part

To model this scenario, we will use graphs with many attributes. The approach presented in the previous sections could be easily extended to families of attributes. Alternatively, one could use just one record attribute, but we prefer the former representation since the specification becomes more readable. The attributes that will be used are:

**Vertex attributes:** `nodeType`, represent the different entities involved in this system, that is, cloud administrator, users, machines and virtual machines. In the graphical notation, this attribute will be denoted by a corresponding image (nodeName1, nodeName2, nodeName3 and nodeName4, resp.); `ident`, models the identifier of the vertex; `size`, denotes the size of the machine and virtual machine; `free`, describes the amount of unused space in a machine; `type`, describes the type of a virtual machine (as a simplification, we assumed that there is a set of standard virtual machines that may be requested by users, identified by their types); `config`, this models the internal configuration of the cloud administrator, probably this would be a set of tables and variables describing the current state of machines and virtual machines;

**Edge attributes:** `edgeType`, some arcs will represent physical relations (like a cloud administrator is connected to all machines monitored by it) or "knows"-relations (like a user may know a cloud administrator) and others will represent messages that are sent in the system. Messages will be denoted by dashed arrows, all other relations will be solid edges; `type`, analogous to the types of vertices; `id`, used in messages that require a parameter (identifier of a virtual machine).

The data types used in the state graph are defined in specification `CloudSp` (Figure 1). This specification includes sorts for booleans and natural numbers with usual operations and equations, sort `T` for the different types of virtual machines, and a sort `C` to describe configurations of a cloud administrator. Such configurations are records containing the current status of the cloud. Due to space limitations, we will not define details of configurations, just use some basic operations (equations will be also omitted).

For example, the graph `G1` depicted in Fig. 2 describes two users and one cloud administrator that knows one machine, `M1`, and two types of virtual machines, `T1` and `T2`. Actually, the administrator stores the images of the corresponding virtual machines such that, when a request is done, it creates a copy of this image in an available machine. Images are modelled by a special identifier (0). There are also two request messages, one from each user.

6.2 Cloud Administration: Dynamic Part

Figure 2 also shows some rules that describe the behaviour of the cloud administrator. Rule `CreateVM` models the creation of a new virtual machine. This may happen when there is a request from a user (dashed edge in `L1`) having as
Cloud_Sp :
sorts B, N, C, T
opns
  ... boolean operators...
  ... natural numbers operators...
  newId: C × N → B checks whether an id is not used in a config
  enoughSpace: C × N → B checks if there is enough space in a config
  newVM: C × N × N × N × T → C includes a new virtual machine in a config
  replVM: C × N × N → C replicates a virtual machine in a config
  newMch: C × N × N × Nat → C includes a new machine in a config
  mergeMch: C × N × N → C merges two machines in a config
  replicateAdm?: C → B checks whether a new administrator is needed
eqns
  ...

Fig. 1. Specification Cloud_Sp

attribute the type of virtual machine that is created and the cloud administrator has a corresponding image and a machine to install this VM. Some additional constraints over the attributes are modelled by equations (written below the rule): the identifier that will be used for the new VM is fresh (newId(c, idVM)), there is enough free space in the chosen machine (nVM ≤ f). The remaining equations describe the values that some attributes will receive when this rule is applied: variable f' depicts the amount of free space in the machine after the installation of the new VM, and c' is the updated configuration of the cloud administrator. Note that the two instances of the VM in K1 are copies of the corresponding vertex in L1, just the identifier attribute in the second copy is left undefined, the attributes config and free are also undefined, since their values will change. Finally, in R1, this second copy is updated with the new identifier (idVM) and it is installed in the machine and sent to the user, and the attributes of the cloud administrator and machine are updated accordingly. Application of this rule to graph G1 is given by the span G1 ← D → G2 on top of Fig. 2.

Rule replicateVM creates a copy (replica) of a VM in another physical machine. This operation is important for fault tolerance reasons. When this rule is applied, all references to the original VM will also point to the new VM. The configuration of the cloud administrator is updated because any change in one virtual machine must now be propagated to its copy. Rule replicateAdm is used to replicate the cloud administrator itself. This kind of operation may be necessary, for example, when the number of clients becomes too large or for dependability reasons. The rule that specifies the operation has an equation that checks whether this replication is needed (replicateAdm?(c)). In case this is true in the current configuration, the administrator is copied and the two

---

4 To enhance readability, when working with boolean expressions in equations, we omit the right side of the equation. For example, we write simply newId(c, Id) instead of newId(c, Id) = true.
Fig. 2. Graph and Rules of the Cloud Administrator
configurations (the original and the copy) are updated (because now they must know that some synchronisation is needed to perform the operations). Since these are copies, they manage the same machines and VMs, but now clients may send requests to either of the administrators (when this rule is applied, all edges that were connected to one administrator will also be connected to the copy).

Rules \textit{TurnOnMachine} and \textit{TurnOffMachine} model the creation and deletion of machines in the system. We assumed that there is an unlimited number of machines that may be connected to the system, and thus there is a need for more capacity (not\((\text{enoughSpace}(c, nVM))\) is true), a new machine may be added. We specified a simple version of turning off a machine by merging the vertices that correspond to two different machines. This can be done if the administrator notices that there is enough free space in one machine to accommodate VMs that are in another machines (\((nM1 - f1 \leq f2)\) is true). When this rule is applied, all VMs that were in both machines will end up in the machine with identifier \textit{id2}.

7 Related Work

Various definitions of attributed graphs have been proposed in the literature. Labelled graphs, e.g. [16], in which attributes are limited to a simple set of a vocabulary, could be considered as a first step towards attributed graphs. Such a set of vocabulary can be replaced by a specific, possibly infinite, set (of attributes) such as integers yielding particular definition of attributed graphs. This approach has been proposed for instance in [20] and could be considered as a particular case of the definition of attributed graphs we proposed in this paper.

The most popular way to define the data part in attributed graphs is based on algebraic specifications, see e.g. [18,17,4,10]. E-Graphs [10] is one of the principal contribution in this perspective, where an attributed graph gathers, in addition to its own vertices and edges, additional vertices and edges corresponding to the attribution part. The latter vertices correspond to possible attribution values. Such vertices might be infinite whenever the set of attributes is infinite. An attribution edge goes from a vertex or an edge of the considered graph to an attribution vertex. Attribution edges are used to represent graphically attribution functions. Due to the representation of each attribute as a vertex, an E-graph is infinite in general.

To overcome the infinite structures of E-graphs, Symbolic graphs [19] have been proposed. They are E-graphs which have variables as attributes. Such variables can be constrained by means of first order logic formulae. Hence a symbolic graph represents in concise way a (possibly infinite) set of (ground) E-graphs.

In this paper, we have proposed a general definition of attributed structures where the data part is not necessarily specified as an algebra. Our approach is very close to the recent paper by U. Golas [15] where an attributed graph is also defined as a tuple \((G, A, \alpha)\) where \(G\) is a given structure, \(A\) consists of attribution values and \(\alpha\) is a family of partial attribution functions. The main difference with our proposal lies in the consideration of attribution functions \(\alpha\). For sake
of simplicity, we considered simply partial functions for $\alpha$. Generalization to families of functions as in [15] is straightforward.

Besides the variety of definitions of attributed graphs as mentioned above, attributed graph transformation rules have been based mainly on the double pushout approach which departs from the sesquipushout approach we have used in our framework. For a comparison of the double and the sesquipushout approaches we refer the reader to [6]. As far as we are aware of, the present paper presents the first study of attributed graph transformations following the sesquipushout approach and thus featuring the possibility of vertex and edge cloning in presence of attributes. Thanks to partial morphisms, rules allow also deletion and change of attributes.

8 Conclusion

In this paper we presented an approach to transformations of attributed structures that allows cloning and merging of items. This approach is based on the SqPO approach to graph transformations, and thus also allows deletion in unknown context. Concerning the attributes, our framework is general in the sense that many different kinds of attributes can be used (not just algebras, as in most attributed graph transformation definitions) and allows that rules change the attributes associated to vertices/edges. The resulting formalism is very interesting and we believe that it can be used to provide suitable specifications of many classes of applications like cloud computing, adaptive systems, and other highly dynamically changing systems.

As future work, we plan to develop more case studies to understand the strengths and weaknesses of this formalism for practical applications. We also want to study analysis methods. Since we are allowing non-injective rules, great part of the theory of graph transformations can not be used directly and we need to investigate which results may hold. Concerning verification of properties, we intent to extend the analysis of graph transformations using theorem provers [8] to attributed SqPO-rewriting.

Appendix

Theorem 1 about the lifting of sesqui-pushouts from the category of structures $G$ to the category of attributed structures $\text{PAttG}$ relies on two Propositions which are stated and proved in this Appendix: Proposition 1 about the lifting of pushouts in Section A and Proposition 2 about the lifting of final pullback complements in Section B.

A Lifting Pushouts to attributed structures

Remark 2. In the category of sets, let us consider a commutative square as follows:

$$
\begin{array}{c}
X \\
\downarrow i \\
Y \\
\downarrow f_1
\end{array}
\begin{array}{c}
\quad f \\
\quad (=) \\
\quad i' \\
\downarrow f_1
\end{array}
\begin{array}{c}
X' \\
\downarrow i' \\
Y'
\end{array}
$$

Let us assume that $i$ is an inclusion, so that $Y = X + C$ where $C$ is the complement of $X$ in $Y$. This square is a PO (up to isomorphism) if and only if $i'$ is an inclusion, so that $Y' = X' + C'$ where $C'$ is the complement of $X'$ in $Y'$, and moreover $C' = C$ and $f_1 = f + id_C$:

$$
\begin{array}{c}
X \\
\downarrow i \\
Y = X + C \\
\downarrow f_1 = f + id_C
\end{array}
\begin{array}{c}
\quad f \\
\quad (PO) \\
\quad i' \\
\downarrow f_1 = f + id_C
\end{array}
\begin{array}{c}
X' \\
\downarrow i' \\
Y' = X' + C
\end{array}
$$

It follows that injections are stable under POs in $\text{Set}$.

Proposition 1. Let us assume that the functor $S : G \to \text{Set}$ preserves POs. Then the functor $U_G : \text{PAttG} \to G$ lifts POs of matchings along attribute-preserving morphisms, in the following precise way. Let $(r, id_A) : \hat{K} \to \hat{R}$ be a morphism in $\text{PAttG}$. Let $(m_K, a) : \hat{K} \to \hat{D}$ be a matching, so that we can denote $SD = SK + C$ with $Sm_K$ the canonical inclusion. Let $\Delta_{po}$ (below on the left) be a PO in $G$, then we can denote $SH = SR + C$ with $Sm_R$ the canonical inclusion and $Sr_1 = Sr + id_C$. Let $\alpha_H : SH \to JA_1$ be defined as $Ja \circ \alpha_R$ on $SR$ and as $\alpha_D$ on $C$. Then $(m_R, a)$ is a matching, $(r_1, id_{A_1})$ is a morphism in $\text{PAttG}$ and $\hat{\Delta}_{po}$ (below on the right) is a PO in $\text{PAttG}$.

\[ \Delta_{po} : \]

\[ \hat{\Delta}_{po} : \]
Proof. We have:

- \( SD = SK + C \) with coprojections \( Sm_K : SK \to SD \) and (say) \( i_D : C \to SD \),
- \( SH = SR + C \) with coprojections \( Sm_R : SR \to SH \) and (say) \( i_H : C \to SH \),
- \( Sr_1 \) is characterized by \( Sr_1 \circ i_D = i_H \) and \( Sm_K \circ Sr = Sm_R \circ Sr \),
- \( \alpha_H \) is defined by \( \alpha_H \circ i_H = \alpha_D \circ i_D \) and \( \alpha_H \circ Sm_R = Ja \circ \alpha_R \).

We have to check the following properties.

- \( \Delta_p \) is a matching in \( \text{PAttG} \). Indeed, \( \alpha_H \circ Sm_R = Ja \circ \alpha_R : SR \to JA_1 \) by definition of \( \alpha_H \) and \( Sm_R \) is an injection by assumption.
- \( (r_1, id_{A_1}) \) is a morphism in \( \text{PAttG} \). This means that \( \alpha_H \circ Sr_1 \geq \alpha_D : SD \to JA_1 \), which is equivalent to \( \alpha_H \circ Sr_1 \circ i_D \geq \alpha_D \circ i_D : C \to JA_1 \) and \( \alpha_H \circ Sm_K \geq \alpha_D \circ Sm_K : SK \to JA_1 \).
  - On \( i_D(C) \) we have \( \alpha_H \circ Sr_1 \circ i_D = \alpha_H \circ i_H = \alpha_D \circ i_D \).
  - On \( m_K(SK) \) we have \( \alpha_H \circ Sr_1 \circ Sm_K = \alpha_H \circ Sm_R \circ Sr = Ja \circ \alpha_R \circ Sm_K \).
    We know that \( \alpha_R \circ Sr \geq \alpha_K \) because \( (r, id_A) \) is a morphism in \( \text{PAttG} \), thus we get \( \alpha_H \circ Sr_1 \circ Sm_K \geq Ja \circ \alpha_K \). And we know that \( \alpha_D \circ Sm_K = Ja \circ \alpha_K \) because \( (m_K, a) \) is a strict morphism in \( \text{PAttG} \), so that we get \( \alpha_H \circ Sr_1 \circ Sm_K \geq \alpha_D \circ Sm_K \).
- \( \Delta_{po} \) is a commutative square in \( \text{PAttG} \). This is obvious, since both its underlying square in \( G \) and its underlying square in \( A \) are commutative.
- \( \Delta_{po} \) is a PO in \( \text{PAttG} \). Let us consider a commutative square in \( \text{PAttG} \):

\[
\begin{array}{ccc}
(K, A, \alpha_K) & \xrightarrow{(r, id_A)} & (R, A, \alpha_R) \\
\downarrow{(m_K, a)} & \downarrow{(m', a')} & \downarrow{(r', b)} \\
(D, A_1, \alpha_D) & \xrightarrow{(r_1, id)} & (H, A_1, \alpha_H)
\end{array}
\]

and let us look for a morphism \( (f, c) : (H, A_1, \alpha_H) \to (H', A', \alpha') \) in \( \text{PAttG} \) such that \( (f, c) \circ (m_R, a) = (m', a') \) and \( (f, c) \circ (r_1, id_{A_1}) = (r', b) \).

Thus, we are looking for:

- A morphism \( f : H \to H' \) in \( G \) such that \( f \circ m_R = m' \) and \( f \circ r_1 = r' \):
  there is exactly one choice for \( f \) since \( \Delta_{po} \) is a PO in \( G \).
- A morphism \( c : A_1 \to A' \) in \( A \) such that \( c \circ a = a' \) and \( c \circ id_{A_1} = b \):
  there is exactly one choice for \( c \) (since \( b \circ a = a' \)), it is \( c = b \).
Let us assume that \( i \) follows:

In the category of sets, let us consider a commutative square as follows:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & X' \\
\downarrow & & \downarrow \\
Y & \xrightarrow{f_1} & Y'
\end{array}
\]

Remark 3. In the category of sets, let us consider a commutative square as follows:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & X' \\
\downarrow & & \downarrow \\
Y & \xrightarrow{f_1} & Y'
\end{array}
\]

Let us assume that \( i \) is an inclusion, so that \( Y = X + C \). This square is a PB (up to isomorphism) if and only if \( i' \) is an inclusion, so that \( Y' = X' + C' \), and \( f_1 = f + \gamma \) for some \( \gamma : C' \rightarrow C \):

\[
\begin{array}{ccc}
X & \xrightarrow{f} & X' \\
\downarrow & & \downarrow \\
Y = X + C & \xrightarrow{f_1=f+\gamma} & Y' = X' + C'
\end{array}
\]
It follows that injections are stable under PBs in $\textbf{Set}$, which is a special instance of the well-known fact that monomorphisms are stable under PBs in all categories. Moreover, this PB is a FPBC (up to isomorphism) if and only if $C' = C$ and $\gamma = \text{id}_C$:

$$
\begin{array}{cccccc}
X & \xrightarrow{f} & X' \\
\downarrow{i} & \downarrow{(FPBC)} & \downarrow{i'} \\
Y = X + C & \xleftarrow{f_1 + \text{id}_C} & Y' = X' + C
\end{array}
$$

**Lemma 1 (PBs in $\text{PAttG}$).** Let us assume that the functors $U_G : \text{PAttG} \rightarrow \text{G}$, $U_A : \text{PAttG} \rightarrow \text{A}$, $S : \text{G} \rightarrow \text{Set}$ and $J : \text{A} \rightarrow \text{Set}$ preserve PBs. Let us consider a PB in $\text{PAttG}$:

$$
\begin{array}{c}
(L, A, \alpha_L) \xleftarrow{\langle l, b \rangle} (K, A', \alpha_K) \\
(m_L, a) \xrightarrow{(PB)} \langle m_K, a' \rangle \\
(G, A_1, \alpha_G) \xleftarrow{\langle l_1, b_1 \rangle} (D, A'_1, \alpha_D)
\end{array}
$$

If $(m_L, a)$ is a matching then $(m_K, a')$ is a matching and $(S_1)^{-1}(Sm_L(SL)) \subseteq Sm_K(SK)$.

**Proof.** Since $S \circ U_G : \text{PAttG} \rightarrow \text{Set}$ preserves PBs, it follows from Remark $\footnote{3}$ that $m_K$ is injective and that $(S_1)^{-1}(Sm_L(SL)) \subseteq Sm_K(SK)$. It remains to prove that $(m_K, a')$ is strict. If this does not hold, then there is some $x \in SK$ such that $x \notin D(\alpha_K)$ and $Sm_K(x) \in D(\alpha_D)$. Let $y = Sm_K(x)$, $x_0 = Sl(x)$ and $y_0 = l_1(y) = m_L(x_0)$. Since $y \in D(\alpha_D)$, $(l_1, b_1)$ is a morphism and $(m_L, a)$ a strict morphism, we have $y_0 \in D(\alpha_G)$ and $x_0 \in D(\alpha_L)$. More precisely, let $y : u$ and $x_0 : t_0$, then $y_0 : u_0$ where $u_0 = a(t_0) = b_1(u)$. Since $J \circ U_A : \text{PAttG} \rightarrow \text{Set}$ preserves PBs, there is a unique $t \in JA'$ such that $t_0 = Jb(t)$ and $u = Ja'(t)$. Let us define $K' = (K, A', \alpha_K')$ where $\alpha_K'$ extends $\alpha_K$ simply by mapping $x$ to $t$. Then $b$ and $a'$ may be extended accordingly. The resulting square is commutative in $\text{PAttG}$ but there is no morphism from $K'$ to $K$ in $\text{PAttG}$, which contradicts the fact that the given square is a PB in $\text{PAttG}$.

**Proposition 2.** Let us assume that the functors $U_G : \text{PAttG} \rightarrow \text{G}$, $U_A : \text{PAttG} \rightarrow \text{A}$, $S : \text{G} \rightarrow \text{Set}$ and $J : \text{A} \rightarrow \text{Set}$ preserve PBs. Then the functor $U_G : \text{PAttG} \rightarrow \text{G}$ lifts FPBCs of matchings along attribute-preserving morphisms, in the following precise way. Let $(l, id_A) : K \rightarrow \tilde{L}$ be a morphism in $\text{PAttG}$. Let $(m_L, a) : \tilde{L} \rightarrow \tilde{G}$ be a matching, so that we can denote $SG = SL + C$ with $Sm_L$ the canonical inclusion. Let $\Delta_{fpbc}$ (below on the left) be a FPBC in $\text{G}$, then we can denote $SD = SK + C_1$ with $Sm_K$ the canonical inclusion and $S_1 = Sl + \gamma$ for some $\gamma : C_1 \rightarrow C$, by Remark $\footnote{3}$. Let $\alpha_D : SD \rightarrow JA_1$ be defined as $Ja \circ \alpha_K$ on $SK$ and as $\alpha_G \circ S_1$ on $C_1$. Then $(m_K, a)$ is a matching, $(l_1, id_A)$
is a morphism in $\text{PAttG}$ and $\tilde{\Delta}_{fpbc}$ (below on the right) is a $\text{FPBC}$ in $\text{PAttG}$.

$$
\Delta_{fpbc}:
\begin{array}{ccc}
L & \xrightarrow{l} & K \\
m_L & \downarrow{(FPBC)} & m_K \\
G & \xleftarrow{i_1} & D
\end{array}
\quad
\tilde{\Delta}_{fpbc}:
\begin{array}{ccc}
(L, A, \alpha_L) & \xleftarrow{(l, id_A)} & (K, A, \alpha_K) \\
(m_L, a) & \downarrow{(FPBC)} & (m_K, a) \\
(G, A_1, \alpha_G) & \xleftarrow{(l_1, id_A_1)} & (D, A_1, \alpha_D)
\end{array}
$$

**Proof.** We have:

- $SD = SK + C_1$ with coprojections $Sm_K : SK \to SD$ and (say) $i_D : C_1 \to SD$.
- $\alpha_D$ is defined by $\alpha_D \circ i_D = \alpha_G \circ Sl_1 \circ i_D$ and $\alpha_D \circ Sm_K = Ja \circ \alpha_K$.

We have to check the following properties.

- $(m_K, a)$ is a matching in $\text{PAttG}$. Indeed, $\alpha_D \circ Sm_K = Ja \circ \alpha_K : SK \to JA_1$ by definition of $\alpha_D$ and $Sm_K$ is an injection by assumption.
- $(l_1, id_A_1)$ is a morphism in $\text{PAttG}$. This means that $\alpha_G \circ Sl_1 \geq \alpha_D : SD \to JA_1$, which is equivalent to $\alpha_G \circ Sl_1 \circ i_D \geq \alpha_D \circ i_D : C_1 \to JA_1$ and $\alpha_G \circ Sl_1 \circ Sm_K \geq \alpha_D \circ Sm_K : SK \to JA_1$.
  - On $i_D(C_1)$ we have $\alpha_G \circ Sl_1 \circ i_D = \alpha_D \circ i_D$.
  - On $m_K(SK)$ we have $\alpha_G \circ Sl_1 \circ Sm_K = \alpha_G \circ Sl \circ Sl$ since the square $\Delta_{fpbc}$ is commutative. We know that $\alpha_G \circ Sm \leq Ja \circ \alpha_L$ because $(m_K, a)$ is a morphism in $\text{PAttG}$, and that $\alpha_L \circ Sl \geq \alpha_K$ because $(l, id_A)$ is a morphism in $\text{PAttG}$, thus we get $\alpha_G \circ Sm \circ Sl \geq Ja \circ \alpha_L \circ Sl \geq Ja \circ \alpha_K$, so that $\alpha_G \circ Sl_1 \circ Sm_K \geq Ja \circ \alpha_K$. From the definition of $\alpha_D$ on $m_K(SK)$ we get $\alpha_G \circ Sl_1 \circ Sm_K \geq \alpha_D \circ Sm_K$.
- $\tilde{\Delta}_{fpbc}$ is a commutative square in $\text{PAttG}$. This is obvious, since both its underlying square in $G$ and its underlying square in $A$ are commutative.
- $\Delta_{fpbc}$ is a PB in $\text{PAttG}$. Let us consider a commutative square in $\text{PAttG}$:

$$(L, A, \alpha_L) \xleftarrow{(l', b)} (K', A', \alpha')$$

and let us look for a morphism $(f, c) : (K', A', \alpha') \to (K, A, \alpha_K)$ in $\text{PAttG}$ such that $(m_K, a) \circ (f, c) = (m', a')$ and $(l, id_A) \circ (f, c) = (l', b)$.

$$
\begin{array}{ccc}
(L, A, \alpha_L) & \xleftarrow{(l, id)} & (K, A, \alpha_K) \\
(m_L, a) & \downarrow{(m_K, a)} & (m_K, a) \\
(G, A_1, \alpha_G) & \xleftarrow{(l_1, id)} & (D, A_1, \alpha_D)
\end{array}
\quad
\begin{array}{ccc}
(K', A', \alpha') & \xleftarrow{(f', c)} & (K', A', \alpha') \\
(l_1, id_A_1) & \downarrow{(l_1, id_A_1)} & (l_1, id_A_1) \\
(D, A_1, \alpha_D) & \xleftarrow{(l_1, id_A_1)} & (D, A_1, \alpha_D)
\end{array}
$$
Thus, we are looking for:

- A morphism $f : K' \to K$ in $G$ such that $m_K \circ f = m'$ and $l \circ f = l'$; there is exactly one choice for $f$ since $\Delta_{f_{\text{pb}}}^c$ is a PB in $G$.
- A morphism $c : A' \to A$ in $A$ such that $a \circ c = a'$ and $id_A \circ c = b$; there is exactly one choice for $c$ (since $a \circ b = a'$), it is $c = b$.

Now we have to check that $\alpha_K \circ Sf \geq Jb \circ \alpha'$: $SK' \to JA$. Let us denote $\varphi = \alpha_K \circ Sf$ and $\varphi' = Jb \circ \alpha'$.

- Let $\varphi'' = \alpha_L \circ Sl'$ and let us prove that $\varphi'' \geq \varphi$ and $\varphi'' \geq \varphi'$. Since $(l, id_A)$ is a morphism in $\text{PAttG}$ we have $\alpha_L \circ Sl \geq \alpha_K$, and since $l' = l \circ f$ this implies that $\varphi'' = \alpha_L \circ Sl' \geq \alpha_K \circ Sf = \varphi$. Since $(l', b)$ is a morphism in $\text{PAttG}$ we have $\varphi'' = \alpha_L \circ Sl' \geq Jb \circ \alpha' = \varphi'$. Thus, there is a partial function $\varphi''$ such that $\varphi'' \geq \varphi$ and $\varphi'' \geq \varphi'$. It follows that $\varphi$ and $\varphi'$ coincide on $D(\varphi') \cap D(\varphi)$. So, if we can prove that $D(\varphi') \subseteq D(\varphi)$ then we will get $\varphi \geq \varphi'$, as required.

- Now, let us consider a PB in $\text{PAttG}$ such that $(m_K, a)$ is a strict morphism in $\text{PAttG}$ we have $\alpha_D \circ Sm_K = Jb \circ \alpha_K$, so that $Jb \circ \varphi = Jb \circ \alpha_K \circ Sf = \alpha_D \circ Sm_K \circ Sf$ since $(m', a')$ is a morphism in $\text{PAttG}$ we have $\alpha_D \circ Sm' \geq Jb \circ \alpha'$. With $m' = m_K \circ f$ and $a' = a \circ b$ we get $\alpha_D \circ Sm_K \circ Sf \geq Jb \circ \alpha'$. Thus, we have $Ja \circ \varphi \geq Ja \circ \varphi'$. This implies that $D(Ja \circ \varphi') \subseteq D(Ja \circ \varphi)$, and since $Ja$ is a total function this means that $D(\varphi') \subseteq D(\varphi)$. It follows that $\varphi \geq \varphi'$, as explained above.

$\hat{\Delta}_{f_{\text{pb}}}^c$ is a FPBC in $\text{PAttG}$. Let us consider a PB in $\text{PAttG}$:

$$(L, A, \alpha_L) \xleftarrow{(l, b)} (K', A', \alpha'_{K})$$

$$(G, A_1, \alpha_G) \xleftarrow{(l', b_1)} (D', A_1', \alpha'_{D})$$

with a morphism $(f, c) : (K', A', \alpha'_{K}) \to (K, A, \alpha_K)$ in $\text{PAttG}$ such that $(l, id_A) \circ (f, c) = (l', b)$, which implies that $c = b$. And let us look for a morphism $(f_1, c_1) : (D', A_1', \alpha'_{D}) \to (D, A_1, \alpha_D)$ in $\text{PAttG}$ such that $(f_1, c_1) \circ (m', a') = (m_K, a) \circ (f, c)$ and $(l_1, id_{A_1}) \circ (f_1, c_1) = (l', b_1)$.

Thus, we are looking for:
A morphism $f_1 : D' \to D$ in $\mathbf{G}$ such that $f_1 \circ m' = m_K \circ f$ and $l_1 \circ f_1 = l'_1$; there is exactly one choice for $f_1$ since $\Delta_{fpcs}$ is a FPBC in $\mathbf{G}$.

A morphism $c_1 : A'_1 \to A_1$ in $\mathbf{A}$ such that $c_1 \circ a' = a \circ c$ and $\text{id}_{A_1} \circ c_1 = b_1$; there is exactly one choice for $c_1$ (since $b_1 \circ a' = a \circ b$ and $c = b$), it is $c_1 = b_1$.

Now we have to check that $\alpha_D \circ Sf_1 \geq Jb_1 \circ \alpha'_D : SD' \to JA_1$. Let us denote $\psi = \alpha_D \circ Sf_1$ and $\psi' = Jb_1 \circ \alpha'_D$.

Let $\psi'' = \alpha_G \circ S l'_1$ and let us prove that $\psi'' \geq \psi$ and $\psi'' \geq \psi'$.

Since $(l_1, \text{id}_{A_1})$ is a morphism in $\mathbf{PAttG}$ we have $\alpha_G \circ S l_1 \geq \alpha_D$, and since $l'_1 = l_1 \circ f_1$ this implies that $\psi'' = \alpha_G \circ S l'_1 \geq \alpha_D \circ S f_1 = \psi$. Since $(l'_1, b_1)$ is a morphism in $\mathbf{PAttG}$ we have $\psi'' = \alpha_G \circ S l'_1 \geq Jb_1 \circ \alpha'_D = \psi'$. Thus, there is a partial function $\psi''$ such that $\psi'' \geq \psi$ and $\psi'' \geq \psi'$. It follows that $\psi$ and $\psi'$ coincide on $\mathcal{D}(\psi') \cap \mathcal{D}(\psi)$. So, if we can prove that $\mathcal{D}(\psi') \subseteq \mathcal{D}(\psi)$ then we will get $\psi \geq \psi'$, as required.

Now, let us prove that $\mathcal{D}(\psi') \subseteq \mathcal{D}(\psi)$, i.e., $\mathcal{D}(Jb_1 \circ \alpha'_D) \subseteq \mathcal{D}(\alpha_D \circ Sf_1)$.

Since $Jb_1$ and $Sf_1$ are total functions, we have to prove that for each $y' \in SD'$, $y' \in \mathcal{D}(\alpha'_D) \implies Sf_1(y') \in \mathcal{D}(\alpha_D)$. Thus, let us consider some $y' \in \mathcal{D}(\alpha'_D)$, let $y = Sf_1(y')$, and let us prove that $y \in \mathcal{D}(\alpha_D)$. Let $y_0 = S l_1(y) = S l'_1(y')$, since $(l'_1, b_1)$ is a morphism in $\mathbf{PAttG}$ and $y' \in \mathcal{D}(\alpha'_D)$ we have $y_0 \in \mathcal{D}(\alpha_G)$.

* If $y' = S m'(x')$ for some element $x'$ of $SK'$, then let $x_0 = S l'(x')$, so that $y_0 = S l'_1(y') = S l'_1 \circ m'(x') = S m_L(x_0)$. Since $(m_L, a)$ is a strict morphism in $\mathbf{PAttG}$ and $y_0 \in \mathcal{D}(\alpha_G)$ we have $x_0 \in \mathcal{D}(\alpha_L)$. In addition, $S(m_K \circ f)(x') = S(f_1 \circ m'(x')) = S f_1(y') \geq y$. Since we consider a PB in $\mathbf{PAttG}$, Lemma \text{[1]} states that the morphism $(m', a')$ is strict. Thus, since $y' \in \mathcal{D}(\alpha'_D)$, we have $x' \in \mathcal{D}(\alpha'_K)$. Since $x' \in \mathcal{D}(\alpha'_K)$ and since $(f, b)$ and $(m_K, a)$ are morphisms in $\mathbf{PAttG}$ we have $y = S(m_K \circ f)(x') \in \mathcal{D}(\alpha_D)$, as required.

* Otherwise, $y'$ is not in the image of $S m'$. Since we consider a PB in $\mathbf{PAttG}$, Lemma \text{[1]} states that $(S l'_1)^{-1}(S m_L(S L)) \subseteq S m'(SK')$. Thus, since $y' \notin S m'(SK')$, we have $y_0 \notin S m_L(S L)$, i.e., $y_0 \notin C_1$.

Then, according to the definition of $\alpha_D$, we have $y \in \mathcal{D}(\alpha_D)$, as required.

Thus, we have proved that $\mathcal{D}(\psi') \subseteq \mathcal{D}(\psi)$, which implies that $\psi \geq \psi'$, as explained above.

Let us summarize what may occur in $\widehat{\Delta}_{fpcs}$ for an element $x \in SD$ (here $t$ denotes an element of $TA$ and $t_1$ an element of $TA_1$). If $x \in C_1$ then two cases may occur:

\[ x : t_1 \leftarrow x : t_1 \quad x : \bot \leftarrow x : \bot \]

If $x \in SK$ then three cases may occur:

\[ l(x) : t \leftarrow x : t \quad l(x) : t \leftarrow x : \bot \quad l(x) : \bot \leftarrow x : \bot \]

\[ l(x) : a(t) \leftarrow x : a(t) \quad l(x) : a(t) \leftarrow x : \bot \quad l(x) : \bot \leftarrow x : \bot \]
C  Graph transformations with attributes defined equationally

In this appendix we check that the assumptions of Theorem 1 are satisfied in the case of attributed graph transformations with attributes built over equational specifications. The functors \( U_G \) and \( U_A \) are known from Definition 4, we have to choose the categories \( G \) and \( A \) and the functors \( S \) and \( T \). Let \( G = \text{Gr} \) be the category of graphs. Let \( S : \text{Gr} \to \text{Set} \) be the functor which maps each graph to the disjoint union of its set of vertices and its set of edges. Let \( S' \) be some fixed equational specification and let \( A = \text{Mod}(Sp) \) be the category of models of \( Sp \). Let \( T : A \to \text{Set} \) be the functor which maps each model of \( Sp \) to the disjoint union of the carriers sets \( A_s \) for \( s \) in some given set of sorts.

Proposition 3. With the definitions as above, the functors \( U_G : \text{PAttG} \to \text{Gr} \), \( U_A : \text{PAttG} \to \text{Mod}(Sp) \), \( S : \text{Gr} \to \text{Set} \) and \( T : \text{Mod}(Sp) \to \text{Set} \) preserve pullbacks, and \( S \) preserves pushouts.

Proof. The category of graphs is the functor category \( \text{Func}(C_{gr}, \text{Set}) \) where \( C_{gr} \) is the following small category:

\[
\begin{array}{c}
\circlearrowright v \\
\circlearrowleft e \\
\end{array}
\]

It follows that the category \( \text{Gr} \) has limits and colimits, in particular POs and PBs. The functors \( V, E : \text{Gr} \to \text{Set} \) map each graph \( G \) to its set of vertices \( V(G) \) and its set of edges \( E(G) \), respectively, and the functor \( S : \text{Gr} \to \text{Set} \) is \( S = V + E \), which maps each graph \( G \) to the disjoint union \( S(G) = V(G) + E(G) \). The functors \( V \) and \( E \) are the evaluation functors that evaluate each graph \( G \), considered as a functor \( G : C_{gr} \to \text{Set} \), at the objects \( v \) and \( e \) of \( C_{gr} \), respectively: \( V(G) = G(v) \) and \( E(G) = G(e) \). It follows that the functors \( V, E \) and \( S = V + E \) preserve limits and colimits, in particular POs and PBs.

Since \( \text{Mod}(Sp) \) is the category of models of an equational specification \( Sp \), it has limits and colimits. Let \( S' \) be some set of sorts of \( Sp \), i.e., some subset of \( S \). Let \( T_A = \sum_{s \in S'} A_s \) be the disjoint union of the carriers sets \( A_s \) for \( s \) in \( S' \).

The functor \( T \) is such that \( TA = \sum_{s \in S'} A_s \) for some set of sorts \( S' \) of \( Sp \). It preserves limits (but it does not preserve colimits, in general), thus it preserves PBs.

Let \( A_\emptyset \) be the empty model of \( Sp \), defined by the fact that all its carriers are empty: \( A_\emptyset \) is the empty object of the category \( \text{Mod}(Sp) \) and \( TA_\emptyset = \emptyset \). The functor \( U_G \) has a left adjoint, which maps each \( G \) to \( (G, A_\emptyset, \alpha_\emptyset) \) where \( D(\alpha_\emptyset) = \emptyset \). Thus, the functor \( U_G \) preserves limits, especially PBs.

Let \( G_\emptyset \) be the empty graph, it is an initial object of the category \( \text{Gr} \) and \( S(G_\emptyset) = \emptyset \). The functor \( U_A \) has a left adjoint, which maps each \( A \) to \( (G_\emptyset, A, \alpha_\emptyset) \) where \( D(\alpha_\emptyset) = \emptyset \). Thus, the functor \( U_A \) preserves limits, especially PBs.
