Because metastasis is associated with the majority of cancer-related deaths, its prevention is a clinical aspiration. Prostanoids are a large family of bioactive lipids derived from the activity of cyclooxygenase-1 (COX-1) and COX-2. Aspirin impairs the biosynthesis of all prostanoids through the irreversible inhibition of both COX isoforms. Long-term administration of aspirin leads to reduced distant metastases in murine models and clinical trials, but the COX isoform, downstream prostanoid, and cell compartment responsible for this effect are yet to be determined. Here, we have shown that aspirin dramatically reduced lung metastasis through inhibition of COX-1 while the cancer cells remained intravascular and that inhibition of platelet COX-1 alone was sufficient to impair metastasis. Thromboxane A₂ (TXA₂) was the prostanoid product of COX-1 responsible for this antimetastatic effect. Inhibition of the COX-1/TXA₂ pathway in platelets decreased aggregation of platelets on tumor cells, endothelial activation, tumor cell adhesion to the endothelium, and recruitment of metastasis-promoting monocytes/macrophages, and diminished the formation of a premetastatic niche. Thus, platelet-derived TXA₂ orchestrates the generation of a favorable intravascular metastatic niche that promotes tumor cell seeding and identifies COX-1/TXA₂ signaling as a target for the prevention of metastasis.

Because metastasis is associated with the majority of cancer-related deaths, its prevention is a clinical aspiration. Prostanoids are a large family of bioactive lipids derived from the activity of cyclooxygenase-1 (COX-1) and COX-2. Aspirin impairs the biosynthesis of all prostanoids through the irreversible inhibition of both COX isoforms. Long-term administration of aspirin leads to reduced distant metastases in murine models and clinical trials, but the COX isoform, downstream prostanoid, and cell compartment responsible for this effect are yet to be determined. Here, we have shown that aspirin dramatically reduced lung metastasis through inhibition of COX-1 while the cancer cells remained intravascular and that inhibition of platelet COX-1 alone was sufficient to impair metastasis. Thromboxane A₂ (TXA₂) was the prostanoid product of COX-1 responsible for this antimetastatic effect. Inhibition of the COX-1/TXA₂ pathway in platelets decreased aggregation of platelets on tumor cells, endothelial activation, tumor cell adhesion to the endothelium, and recruitment of metastasis-promoting monocytes/macrophages, and diminished the formation of a premetastatic niche. Thus, platelet-derived TXA₂ orchestrates the generation of a favorable intravascular metastatic niche that promotes tumor cell seeding and identifies COX-1/TXA₂ signaling as a target for the prevention of metastasis.

Introduction
Prostanoids are a family of bioactive lipids comprising prostaglandins (e.g., PGD₂, PGE₂, PGF₂α), thromboxane A₂ (TXA₂), and prostacyclin (PGI₂). The rate-limiting step of prostanoid biosynthesis is catalyzed by cyclooxygenase (COX), an enzyme with 2 isoforms, COX-1 and COX-2. Both COX-1 and COX-2 have virtually identical enzymatic activity, mediating the conversion of arachidonic acid into PGG₂ and then into PGH₂, the common precursor of all prostanoids (1). However, the spectrum of prostanoids synthesized by each isoform differs in vivo as a result of distinct expression patterns and functional coupling to prostanoid synthases in different cell types (2). For example, COX-2 is induced in endothelial cells and macrophages during inflammation and wound healing and couples with PGE₂ synthase in those cells to produce proinflammatory PGE₂ (2, 3). In contrast, COX-1 is constitutively expressed. In platelets COX-1 couples with TXA₂ synthase (TXAS) to generate prothrombotic TXA₂, upon procoagulant stimuli (e.g., collagen, thrombin, and adenosine diphosphate [ADP]) (4–6). Because of the differential expression of prostanoid synthases and COX-1 and COX-2, the activity of the 2 isoforms is rarely redundant.

The importance of COX and prostanoid pathways in metastasis is apparent from reports showing that their inhibition greatly curtails metastasis. NSAIDs, including aspirin, that inhibit both COX-1 and COX-2 generally reduce metastasis in clinical studies and murine models (7–9). In some reports specific COX-2 inhibition blocks metastasis (10, 11), but not in others (12). Looking at the downstream prostanoids, inhibition of TXA₂ or of PGE₂ synthesis also reduces metastasis in animal models, while PGI₂ has been reported to inhibit metastasis (11–18), with some exceptions (12, 19). These reports raise the question of whether some prostanoids might be suitable targets for metastasis prevention or therapy.

The possibility of using COX or prostanoid synthesis inhibition as a preventive strategy for metastasis has been highlighted by both clinical and experimental studies. Aspirin is given clinically in a variety of doses to reduce cardiovascular events or inflammation. Because of its unique combination of irreversible inhibition of COX enzymes and short circulating half-life, low-dose aspirin preferentially inhibits COX-1 in platelets, reducing the production of prothrombotic TXA₂ and other prostanoids (20). Thus, low-dose aspirin is given for prophylaxis of myocardial infarction and stroke. Higher doses of aspirin inhibit both COX isoforms in other tissues (21). In particular, the reduction of COX-2-derived PGE₂ exerts antiinflammatory effects. Case-control studies and meta-analysis of randomized controlled trials have shown that aspirin given for these unrelated purposes reduces metastatic cancer (22, 23). This effect was significant over a range of primary tumor types, with a

they are crucial and which prostanoids might be responsible for their effects.

Here we demonstrate using a variety of different models that specific inhibition of COX-1 in platelets is sufficient to inhibit metastasis to the same extent as aspirin whereas inhibition of COX-2 does not reduce metastatic colonization. We further show that COX-1 blockade leading to inhibition of TXA₂ synthesis in platelets is sufficient to inhibit metastasis. Lastly we provide evidence that the antimetastatic effect of COX-1 inhibition is generally limited to the early stages of metastasis and that inhibition of COX-1 or of TXA₂ synthesis prevents the formation of an intravascular metastatic and premetastatic niche.

**Results**

**Reduction of metastasis by aspirin correlates with the inhibition of thrombosis.** We treated mice with different doses of aspirin (ASA; low, medium, and high), which were based on the low, medium, and high doses used in humans according to a body surface area dose conversion method and on previous literature (8, 36–38). Inhibition of COX-1 was evaluated using serum levels of TXB₂, a stable metabolite of TXA₂ generated by platelet COX-1 activity during clotting (ex vivo) (Figure 1A and ref. 39). Greater than 95% reduction in TXB₂ ex vivo is thought to indicate physiological inhibition of COX-1 (40). The medium and high doses, but not the low dose, of aspirin reduced TXB₂ more than 95% (Figure 1B) and, correspondingly, reduced COX-1-dependent (arachidonic acid and U46619, a stable analog of TXA₂) agonist-induced platelet aggregation (Figure 1, C and D). COX-1-dependent (ADP) platelet aggregation was not affected (Figure 1, C and D). Importantly, low-dose aspirin did not reduce serum TXB₂ more than 95% over 6 days after the treatment began, suggesting that the drug does not accumulate over time (Supplemental Figure 1; supplemental material available online with this article; https://doi.org/10.1172/JCI121985DS1).
Spontaneous metastasis was also inhibited by aspirin. BALB/c mice with 4T1-GFP-derived subcutaneous tumors received vehicle or aspirin treatment (Figure 2E). Tumor growth was similar in both treatment groups, although aspirin treatment was associated with enhanced tumor regression (Supplemental Figure 4A). Aspirin decreased numbers of lung and liver metastases, of disseminated tumor cells in the lungs (F–I) and of circulating tumor cells (CTCs) (Supplemental Figure 4B) and the invasive ability of those CTCs (Supplemental Figure 4, C–E). These data confirmed the inhibitory effect of aspirin on metastasis at doses that inhibit COX-1 activity and thrombosis, suggesting that aspirin affects metastasis establishment through an antithrombotic effect.

COX-1 inhibition is sufficient to reduce metastasis. Since aspirin inhibits both COX-1 and COX-2 at metastasis-suppressive doses, we determined the effect on metastasis of selective inhibitors of COX-1 (SC-560) or COX-2 (NS-398). Isomeric specificity was confirmed by reduction of serum TXB2 for COX-1 (Figure 3A) and plasma PGE2 for COX-2 (Figure 3B and Supplemental Figure 2). COX-1 inhibition by SC-560 significantly reduced the number of metastatic lung nodules from B16F10 cells (Figure 3, C and D) compared to the medium and high doses of aspirin (Figure 2B). COX-2 inhibition by NS-398 did not reduce the numbers (Figure 3, C and D), making it unlikely that metastatic seeding requires PGE2. However, NS-398–treated mice had smaller metastatic colonies (Figure 3, E and F), compatible with the reported involvement of COX-2 in tumor cell proliferation (15). Using other models, SC-560 also reduced experimental lung metastasis from MC-38-GFP, 4T1, and MDA-MB-231-CFP cells (Supplemental Figure 3) and spontaneous lung and liver metastasis, pulmonary dissemination (Figure 3, G–J), and CTCs and their invasiveness from 4T1-GFP tumor-bearing mice (Supplemental Figure 4, B–E).

Fewer experimental metastases were generated by B16F10 cells in COX-1–/– (Ptgs1–/–, indicated here as COX-1–/–) mice than in wild-type (COX-1+/+) (Figure 4, A and B). As expected, COX-1–/–

Since COX-2 is not significantly expressed in blood cells in the absence of inflammation, we assayed COX-2 inhibition using plasma PGE2, after COX-2 induction by LPS (Figure 1, A and E, and ref. 41). All doses of aspirin reduced plasma PGE2 levels, demonstrating inhibition of COX-2 (Figure 1F). Systemic PGE2 metabolites (PGE2M) were also reduced (Supplemental Figure 2). The antinflammatory effect of low-dose aspirin has been previously suggested (37, 42). Thus aspirin inhibited COX-2 at all doses but only inhibited COX-1 with physiological significance at the medium and high doses. Hence, the medium dose is the minimum dose to achieve antithrombotic effects in our model, similar to low-dose aspirin in humans.

The effects of aspirin on experimental metastasis were assessed in mice treated with aspirin starting 2 days before the i.v. injection of syngeneic B16F10 melanoma tumor cells (Figure 2A). Aspirin at the medium and high doses reduced the number of metastatic lung nodules by more than 50% (Figure 2, B and C). The number of colonies inversely correlated with aspirin intake (Figure 2D). Aspirin (medium dose) similarly reduced the number of metastatic lung nodules from MC-38-GFP, 4T1, and MDA-MB-231-CFP cells (Supplemental Figure 3), indicating a widespread inhibitory effect of aspirin on metastasis.
The inhibition of COX-1 is sufficient to reduce metastasis. 

(A and B) Concentration of TXB₂ in serum (n = 3) (A) or PGE₂ in LPS-stimulated plasma (n = 4) (B; see also Figure 1E) from mice treated with vehicle, SC-560, or NS-398 for 2 days. 

(C and D) B16F10 metastatic lung nodules in lungs from C57BL/6 mice treated with vehicle or drugs (n = 16, 12, and 16) as in Figure 2A.

Control groups are the same as in Figure 2, F and H. Data are represented as mean ± SD. One-way ANOVA with Tukey’s multiple-comparisons test. *0.01 < P ≤ 0.05; **0.001 < P ≤ 0.01; ***P ≤ 0.001.
plasma levels of TXA$_2$ (Figure 6B) and platelet aggregation (Figure 6, C and D), demonstrating inhibition of TXAS activity and TXA$_2$/TXB$_2$ signaling. Treatment of mice with picotamide significantly reduced the number of B16F10 (Figure 6, E and F) and 4T1 (Supplemental Figure 3B) metastatic lung nodules. Picotamide treatment during the intravascular phase of metastasis (PICO→1) reduced the number of metastatic lung nodules (Figure 6G) and decreased the early retention of tumor cells in the lungs (Figure 6, H and D). Furthermore, picotamide decreased the number of disseminated tumor cells in the lungs (Figure 6, J and K), and the number and invasive capacity of CTCs (Supplemental Figure 4, B–E). Similarly, the TP antagonist vapiprost reduced platelet aggregation but not plasma TXB$_2$ (Supplemental Figure 6, A–C), compatible with TP antagonism. Vapiprost impaired the early persistence of tumor cells in the lungs (Supplemental Figure 6, D and E), further supporting the notion that TXA$_2$ signaling is required for early phases of metastatic seeding.

We then supplemented TXA$_2$ using U46619, restoring basal levels of plasma TXA$_2$/TXB$_2$ (Figure 7A) and platelet aggregation (Figure 7, B and C) in aspirin-treated mice. This restored the numbers of persistent tumor cells in the lung to control values in aspirin-treated mice 1 day after injection (Figure 7, D and E) and of experimental metastases, even when U46619 was discontinued 1 day after tumor cell injection (Figure 7, F–H). These results suggest a central role for COX-1–derived TXA$_2$ in the inhibition of metastasis by aspirin.

TXA$_2$ synthesis by COX-1 in platelets is required for metastasis. TXA$_2$ is synthesized by activated platelets and is a potent agonist of platelet aggregation and a secondary mediator of thrombus expansion (4). Platelets aggregate on the surface of B16F10 cells through a TF-dependent mechanism (27). We asked whether inhibition of COX-1 leading to reduced TXA$_2$ levels results in decreased aggregation of platelets on tumor cells and reduced metastasis (8, 26, 45). Fluorescently labeled B16F10 cells (B16F10-CMAC) and platelets (Plts-PKH26) were injected into the opposite tail veins of mice. Platelet aggregation was observed only in the vicinity of the tumor cells, not distantly (Supplemental Figure 7A), suggesting that aggregation was triggered by the tumor cells. Additionally, platelets neither aggregated nor associated with the lung vasculature of naive mice (Supplemental Figure 7B), excluding the possibility that platelet aggregation resulted from euthanasia and its accompanying decreased blood flow. Treatment with aspirin, SC-560, and picotamide, but not NS-398, decreased the number and the size of clots per tumor cell (Figure 8, A–C). Similar results were obtained after coincubation of the 2 cell populations in vitro (Supplemental Figure 8, A–C). Pretreatment of platelets with aspirin and SC-560 diminished platelet aggregation on tumor cells, while pretreatment of tumor cells had no effect (Supplemental Figure 8, D–F). Additionally, COX-1–/– platelets, but not COX-1+/+ platelets, B16F10 cells, nor primary lung microvascular endothelial cells (LMVECs) cells, generated TXB$_2$ either alone or in coculture (Figure 8D). Thus, COX-1 in platelets associated with B16F10 cells is a major source of TXA$_2$, and its inhibition affects platelet aggregation and thrombus expansion on tumor cells.

We then asked whether COX-1 inhibition in reintroduced platelets would reduce metastasis. After platelet depletion by R300 antibody, platelets isolated from vehicle-, ASA-, SC-560–, NS-398–, or PICO-treated mice (Figure 8, G and H) or COX-1+/+ platelets, B16F10 cells, nor primary lung microvascular endothelial cells (LMVECs) cells, generated TXB$_2$, either alone or in coculture (Figure 8D). Thus, COX-1 in platelets associated with B16F10 cells is a major source of TXA$_2$, and its inhibition affects platelet aggregation and thrombus expansion on tumor cells.
platelet-poor plasma (Supplemental Figure 9C) did not restore lung metastasis formation. Platelets from NS-398–treated mice restored metastatic colony formation (Figure 8, G and H). Together these results establish platelets as the COX-1/TXA2–dependent compartment in the establishment of metastasis.

Inhibition of COX-1 reduces the adhesion of tumor cells to endothelium. Tumor cell adhesion to endothelial cells during hematogenous metastasis involves multiple mechanisms (46) and seems to be facilitated by interactions with platelets (47). We investigated tumor cell adhesion to monolayers of LMVECs in the presence of platelets under flow with a low shear stress of 0.05 dyn/cm². Firm tumor cell adhesion to LMVECs was measured after the flow was increased to a higher shear stress (1 dyn/cm²) (Supplemental Figure 10, A and B). Platelet aggregates adhered to tumor cells and formed bridges between tumor cells and LMVECs (Supplemental Figure 10C). Aspirin and SC-560 reduced the adhesion of tumor cells to LMVECs and the association of platelets with tumor cells (Supplemental Figure 10, D–F, and Supplemental Video 1). While the higher shear stress did not alter adhesion of the tumor cells, interestingly, it produced a significant dissociation of platelets from tumor cells under aspirin and SC-560 treatment (Supplemental Figure 10, G–I). These data suggest that COX-1 inhibition can reduce the adhesion of tumor cells to the endothelium.

The COX-1/TXA2 axis in platelets contributes to an intravascular metastatic niche. Microemboli are formed with tumor cells, platelets, and myeloid cells at sites of activated endothelium. The myeloid cells promote the survival of disseminating cells and their development into metastasis (27, 29, 32, 48). Using Cx3cr1gfp/+ mice to visualize monocytes and macrophages (27, 49), we found that aspirin (medium and high doses) and SC-560, but not NS-398 and picotamide, reduced clustering of monocytes/macrophages around the intravascular tumor cells (Figure 9, A and B). The magnitude of monocyte recruitment correlated with the extent of the platelet clots (Figure 9C). Treatment with aspirin, SC-560, and picotamide also reduced the extent of endothelial activation as indicated by E-selectin and VCAM-1 expression in vessels adjacent to platelet–tumor cell aggregates (Figure 9, D–F). Neither monocyte/macrophage recruitment nor endothelial activation was observed in naive mice (Supplemental Figure 7). Additionally, inhibition of COX-1/TXA2 was associated with a larger diameter of lung vessels (Supplemental Figure 11, A–C), suggesting a decrease of vasoconstriction that might further prevent the accumulation of aggregates.

Analogous effects resulted from coinfusion of COX-1−/− platelets and B16F10 cells in COX-1+/+ mice, with a decrease in platelet aggregation on tumor cells (Figure 10, A–C), association of tumor
cells with activated endothelium (Figure 10, D–F), diameter of blood vessels (Supplemental Figure 11, D–F), and recruitment of monocytes/macrophages to tumor cells (Figure 10, G and H) in comparison with mice infused with COX-1+/+ platelets.

The COX-1/TXA2 pathway contributes to a pulmonary premetastatic niche. The ability of disseminated tumor cells to colonize distant sites is enhanced by the systemic effects of a primary tumor, generating a premetastatic niche (50). To test the effect of inhibition of the COX-1/TXA2 pathway on the establishment of a lung premetastatic niche, mice bearing B16F10 subcutaneous tumors were treated with aspirin and injected i.v. with tumor cells to induce lung metastasis before the occurrence of spontaneous metastasis (Figure 11A). Aspirin treatment was started after the initiation of tumor growth and interrupted 2 days before tumor cell injection to avoid a direct effect of platelet inhibition on metastatic seeding. The increased numbers of metastatic lung nodules, indicative of the establishment of a premetastatic niche, were completely abrogated by treatment with aspirin (Figure 11B). Aspirin did not affect the number of nodules in mice without subcutaneous tumors (Figure 11B), further supporting the pro-metastatic role of intact COX-1/TXA2 axis in platelets at the moment of tumor cell injection.

Lung preconditioning has been linked to the recruitment of myeloid cells with the support of the coagulation system (27, 51, 52). The numbers of Cx3CR1-GFP+ monocytes/macrophages in the lungs of mice bearing tumors were greater than those in lungs of naive mice. Aspirin abolished this increase in monocytes/macrophages in the premetastatic lungs (Figure 11C and D) but did not affect the numbers in naive mice (Figure 11C). Taking into account the role of platelets in the recruitment of myeloid cells (27, 29, 33) and the effect of the TXA2 inhibitor picotamide on the establishment of spontaneous metastasis (Figure 6, J and K), together these...
data suggest that the establishment of a lung premetastatic niche depends on the COX-1/TXA₂ pathway in platelets.

TXA₂ signaling, not other platelet activation pathways, is required for the establishment of the intravascular metastatic niche. To understand whether platelet aggregation generally is critical for creating a metastatic niche or whether TXA₂ signaling is more specifically required, we tested clopidogrel, an antagonist of the P2Y₁₂ ADP purinergic receptor, and eptifibatide, an inhibitor of α₁β₃ integrin (also known as GPIIb/IIIa), both used clinically to reduce platelet aggregation (53–56). Clopidogrel and eptifibatide significantly reduced ADP-induced platelet aggregation (Figure 12, A and B) without affecting plasmatic TXB₂ levels in vivo.
In this paper we have provided evidence that aspirin reduces metastasis through the inhibition of platelet COX-1 and its product TXA2. Inhibition of COX-1 activity or TXA2 signaling alone by pharmacological or genetic means was sufficient to reduce metastasis in a range of models. This novel finding directly implicates the activity of COX-1/TXA2 in platelets before and during the intravascular transit of tumor cells, while it is not necessary for the persistent growth of the metastatic lung nodules. The inhibition of COX-1/TXA2 is compatible with a functional COX-1/TXA2 pathway in platelets. Unlike aspirin, clopidogrel and eptifibatide did not affect the early persistence of B16F10 melanoma cells in the lungs (Figure 12, D and E), suggesting that TXA2 signaling in the context of platelet aggregation is essential for the establishment of the early metastatic niche.

All together our data describe a signaling network centered on platelet-derived TXA2 that can be inhibited by aspirin treatment, leading to a reduced seeding efficiency and metastasis (Figure 13).
Aspirin has distinctive pharmacological properties at different doses, mainly derived from the differential inhibition of COXs in different body compartments. The antimetastatic effect of aspirin was seen at doses that inhibited COX-1/TXA$_2$, whereas the inhibition of COX-2/PGE$_2$ alone was not sufficient, COX-1/TXA$_2$ in platelets impairs multiple consecutive steps of the hematogenous transit of tumor cells, leading to the reduction of tumor cells in the lung vasculature. Thus, COX-1 activity and TXA$_2$ production in platelets contribute to the generation of a permissive early metastatic niche (Figure 13).

Figure 9. COX-1/TXA$_2$ inhibition impairs the establishment of a permissive intravascular niche. (A) MIP (median filter) of 3D confocal stacks (×20, top row) and surface reconstruction (bottom row) of tumor cells (B16F10-CMAC, white), platelets (Pits-PKH26, magenta), and Cx,CR1$^+$ monocytes/macrophages (GFP, green) in whole lungs of Cx3cr1$^{gfp/+}$ mice at 8 hours after injection of tumor cells and platelets. Scale bars: 50 μm. (B) Volume of monocyte/macrophage clusters (n = 3). (C) Correlation plot of the volume of monocyte/macrophage clusters versus the volume of clots within the cluster (n = 143). suggesting a prominence of COX-1 rather than COX-2 in the metastatic process. We exclude COX-independent targets (57) since analogous results were obtained with inhibitors of other steps in the COX pathway and in COX-1−/− mice. The antimetastatic effect of aspirin was seen in low- and medium-dose trials (75–300 mg/d), and increased doses did not show additional benefit (23), consistent with platelet COX-1 as the main target for the antimetastatic effect of aspirin. To the best of our knowledge, COX-1 has been previously implicated only marginally in the development of metastasis (58). COX-1 can be expressed by a variety of cell types (21). Reinfusion of platelets in platelet-depleted mice only restored metastasis if the platelets contained active COX-1, showing that it is the platelet supply of COX-1 that is essential to metastasis.

Further, although COX-1 can generate a variety of active prostaglandins, the reduction of TXA2, is responsible for the antimetastatic effect of aspirin. Infusion of a synthetic analog of TXA2 restored the metastatic phenotype during aspirin treatment. Platelets aggregate on the surface of tumor cells and function as circulating reservoirs of TXA2. Autocrine TXA2 signaling in platelets further enhances their aggregation on tumor cells, which supports metastasis (8, 26, 45). Additionally, paracrine TXA2 signaling generates a favorable environment for tumor cell seeding through vascular constriction and induction of E-selectin and VCAM-1 through the TP receptor on endothelial cells (59, 60). Cytokines released from intracellular granules of activated platelets also induce endothelial cell activation (61). Endothelial activation correlates with tumor cell survival within the lung vasculature (32), and E-selectin and VCAM-1 might facilitate tumor cell adherence to the endothelium directly (62) or via bound platelets (63). We demonstrated enhanced adhesion of tumor cells to an LMVEC monolayer in the presence of platelets, analogous to the results in vivo. Concomitantly, endothelial activation facilitates the homing and retention of metastasis-promoting monocytes/macrophages in proximity to the tumor cells (32, 61). Monocyte chemoattractant protein-1 (CCL2/MCP-1) and CCL5 release by endothelial cells following TXA2 signaling might amplify recruitment (29, 64). Altogether, local release of TXA2 leads to the formation of hematogenous microemboli with metastatic properties. The recruitment of monocytes/macrophages was also reduced by aspirin at the level of the premetastatic niche, leading to reduced lung seeding. These data support the notion that cancer-induced thrombosis via the COX-1/TXA2 pathway plays a central role in the conditioning of metastatic sites both before and after the arrival of CTCs (27).

The inhibition of COX-2 decreases metastasis in some models (10, 11) but not others (12). In our experiments, NS-398 did not reduce seeding of B16F10- and 4T1-derived lung metastasis, but it decreased the size of metastatic lung nodules from B16F10 cells, consistent with COX-2 enhancing proliferation and immune evasion in experimental models (65, 66). We noted that inhibition of COX-2 significantly inhibited metastasis by one colorectal cancer cell line, MC-38-GFP. Some colorectal cancers depend on COX-2 for progression (66), and we confirmed that MC-38 cells express much higher levels of COX-2 than B16F10 cells (S. Lucotti, unpublished observations). Thus, the sensitivity to COX-2 inhibition might be indicated by COX-2 expression in cancer cells (67).

In contrast, our data point to COX-1 inhibitors reducing metastasis through a microenvironment-centered mechanism. COX-1 inhibition was effective on cell lines regardless of their COX-1 expression (S. Lucotti, unpublished observations), and COX-1−/− mice had reduced metastasis, suggesting that aspirin has an antimetastatic effect independent of tumor cell expression of COX-1. Using Oncomine gene expression data we found that COX-1 expression in the primary tumor did not correlate with risk of metastatic cancer nor with the antimetastatic effect of aspirin.
However, aspirin significantly increases the risk of severe gastrointestinal symptoms and complications, especially over long-term use. Our data, together with previous clinical trials (71–73), suggest that selective TXA2 inhibitors such as picotamide might present an alternative to target platelet TXA2 while sparing other gastroprotective COX-1 products (i.e., PGI2), and thus might be a safer therapeutic option for the prevention of metastatic disease.

Methods

Animals. C57BL/6 (C57BL/6J), BALB/c (BALB/cAnNCrl), and SCID (CB17/Prkdcscid/lcrIcrIcoCrl) mice were purchased from Charles River Laboratories and Cx3cr1 gfp/+ mice (B6.129P-Cx3cr1 tm1Litt/J) from The Jackson Laboratory (49). COX-1–/– mice (74) were provided by TDW and JAM. Seven- to ten-week-old female mice were used for experiments involving drug treatment and/or tumor cell injection, while older naive mice with a C57BL/6 background were used for blood withdrawal and platelet isolation. Drugs were administered through drinking water, given ad libitum and changed every second day.

Cell lines and staining. B16F10 murine melanoma cells (a gift from John L. Francis, Center for Thrombosis Research, Florida Hospital, Orlando, Florida, USA; ref. 75) were cultured in RPMI 1640 medium (Sigma-Aldrich), 4T1/4T1-GFP murine breast cancer cells, MC-38-GFP murine colorectal cancer cells, and MDA-MB-231-CFP human breast cancer cells (ATCC) were cultured in DMEM (Sigma-Aldrich) in a 5% CO2 humidified atmosphere at 37°C. Media were supplemented with 10% heat-inactivated FBS (Gibco), 2 mM L-glutamine, 25 mM HEPES, 50 U/ml penicillin, and 5 μg/ml streptomycin (Ther-
mo Fisher Scientific), with addition of 0.4 mg/ml G418 or 5 μg/ml puromycin for 4T1-GFP and MC-38-GFP cells, respectively. Primary LMVECs were cultured in 2% gelatin-coated flasks (Sigma-Aldrich) in enriched DMEM (76). Cells were passaged using Versene (B16F10) (Thermo Fisher Scientific) or 0.05% trypsin-EDTA solution (all other cell lines) (Sigma-Aldrich). LMVECs were used within 10 and tumor cells within 20 passages and routinely tested for mycoplasma contamination (MycAlert Mycoplasma Detection Kit, Lonza Group Ltd.). Exponentially growing B16F10 cells (50%–60% confluence) were stained with 12.5 μM solution of CellTracker Blue CMAC, Orange CMRA, or Green CMFDA dye (Thermo Fisher Scientific), following the manufacturer’s instructions.

**Drug formulation for animal studies.** Aspirin (ASA), purchased as DL-lysine acetylsalicylate (Aspègic injectable, Sanofi Aventis), was dissolved in sterile deionized water and resuspended in drinking water at 30 mg/l (low) (37), 180 mg/l (medium) (38), or 625 mg/l (high) (8). SC-560 (Cayman Chemical) dissolved in DMSO (Sigma-Aldrich) was resuspended at 24 mg/l in drinking water supplemented with 0.2% (vol/vol) polyethylene glycol 200 (PEG200) and 0.01% (vol/vol) Tween-20 (both from Sigma-Aldrich) (77). NS-398 (Cayman Chemical) dissolved in DMSO (Sigma-Aldrich) was resuspended at 24 mg/l in drinking water supplemented with 0.2% (vol/vol) polyethylene glycol 200 (PEG200) and 0.01% (vol/vol) Tween-20 (both from Sigma-Aldrich) (77). Picotamide (PICO; Abcam) dissolved in 100% ethanol (Sigma-Aldrich) was resuspended in drinking water at 30 mg/l. U46619 (Cayman Chemical) was dissolved in 100% ethanol (Sigma-Aldrich) was resuspended in sterile water and delivered in saline at 0.5 mg/kg/d through i.p. injection (78).

**Isolation and staining of platelets.** After sacrifice with an overdose of pentobarbital (665 mg/kg, i.p., or 332.5 mg/kg, i.v.), blood was collected from mice by cardiac puncture in syringes containing 3.2% (wt/vol) sodium citrate (Thermo Fisher Scientific) or ACD buffer (83 mM NaC, H2O, 111 mM dextrose, 71 mM citric acid) (Sigma-Aldrich and Fisher Thermo Scientific), at 1:10 vol/vol ratio to blood.

To test aggregation, citrated blood was diluted 1:2 with modified Tyrode’s-HEPES (MTH) buffer (134 mM NaCl, 0.3 mM NaH PO4•2H2O, 3 mM KCl, 5 mM HEPES, 5 mM dextrose, 2 mM MgCl2) (Sigma-Aldrich and Fisher Thermo Scientific) supplemented with 0.02 U/ml apyrase (Sigma-Aldrich) and 0.25 μM PGE1 (Alprostadil, Sigma-Aldrich). After centrifugation at 180 g for 10 minutes at 22°C, the supernatant was collected (platelet-rich plasma [PRP]). The remaining pellet was centrifuged at 12,000 g for 2 minutes at room temperature, and the supernatant was collected (platelet-poor plasma [PPP]).

To prepare washed platelets, PRP was diluted with washing buffer (10% MTH vol/vol in dH2O, 0.10% wt/vol NaHCO3, 0.20% wt/vol BSA, and 1 mM EGTA) and centrifuged at 1300 g for 10 minutes. The platelet pellet was washed twice with washing buffer containing 0.25 μM PGE1. Platelets were counted in a Coulter counter (Beckman; 50-μm aperture tube; 3-30 fl particles). Washed platelets (8 × 105 cells/μl) were stained with PKH26 (Sigma-Aldrich) and readjusted to the required concentration in PPP or resuspension buffer (10% MTH vol/vol in dH2O, 0.10% wt/vol NaHCO3, and 0.20% wt/vol BSA).

**Platelet aggregometry.** Platelet aggregation was evaluated as previously described (79). Briefly, citrated PRP was incubated with agonists arachidonic acid (1 μM; Sigma-Aldrich), U46619 (0.3 μM; Tocris), and ADP (1 M; ChronoLog) or their vehicles in half-area-96-well microtiter plates for 5 minutes at 37°C under 1 mm orbital shaking (Infinite m200 plate reader, Tecan). Aggregated PRP was diluted 1:4 with ACD buffer and labeled with anti-CD61–APC antibody (104316, BioLegend) for 30 minutes at 4°C. Samples were then diluted with 0.01% neutral buffered formalin in PBS (Sigma-Aldrich) and supplemented with 10 pumpCountBright absolute counting beads (Thermo Fisher Scientific). The suspension was analyzed with a FACSCalibur flow cytometer (BD Biosciences). Beads (FL1/SSC-H) were gated and platelets (FL4-H/ SSC-H) were acquired until the count of 100 beads was reached. The total number of single platelets was calculated using FlowJo software.
opposite tail veins of (5 × 10^5) and PKH26-stained platelets (9 × 10^8) were injected into manual segmentation via ImageJ (version 1.46r, NIH) and itk-SNAP μ meters per sample for an isotropic resolution of 125 μm. Ten samples were resuspended in serum-free DMEM and seeded on a Transwell insert (0.16–0.19 mm thick, BD Biosciences). The bottom chamber was assayed with a PGE2 ELISA kit (Abcam). For in vivo PGE2, C57BL/6 mice were injected s.c. in the right flank of female BALB/c mice. Tumors were measured using a digital caliper, and the volume was calculated as height × length × width / π / 6. When the tumor reached 20–30 mm³, mice were randomly allocated to 4 treatment groups (vehicle, aspirin, SC-560, or picotamide). When tumor reached 800 mm³, lungs were perfused/isolated for ex vivo imaging of the left lung. Lung and liver metastatic nodules were counted.

Isolation of CTCs and Transwell invasion assay. Blood from BALB/c mice was drawn in syringes containing ACD buffer (1:5 vol/vol). Whole blood was diluted in an equal volume of PBS, layered on Ficoll-Paque PLUS media solution (GE Healthcare), and centrifuged at 400 g for 30 minutes at 19°C, according to the manufacturer’s instructions. The mononuclear cell layer was isolated, and GFP⁺ cells were counted as CTCs.

For Transwell migration and invasion assays, 5000 CTCs were resuspended in serum-free DMEM and seeded on a Transwell insert (8 μm pore size; BD Biosciences) coated with growth factor reduced Matrigel matrix (2 μg/μl; BD Biosciences). The bottom chamber contained DMEM supplemented with 2% FBS as chemoattractant. After 20 hours, cells adherent to the bottom well were fixed with 2% PFA, and GFP⁺ cells were counted with a Celigo S Imaging Cytometer (Nex-celom Bioscience LLC).

Premetastatic niche formation assay. 5 × 10^5 B16F10 cells were injected s.c. in the back of female C57BL/6 or Cx3cr1gfp/⁻/- mice. Two days after the tumor became palpable (12–15 days from injection), mice were treated with aspirin (medium dose) for 5 days. Treatment was interrupted 2 days before the i.v. injection of 2.5 × 10^6 B16F10 cells. Lungs were collected either just before (Cx3cr1gfp ⁻/- mice, recruitment of myeloid cells) or 2 weeks after tumor cell injection (C57BL/6, metastatic lung nodules).

Isolation and culture of LMVECs. Primary LMVECs were isolated as previously described (76). Briefly, lungs from female C57BL/6 mice were dissected, digested in a 0.5-mg/ml collagenase solution for 1 hour at 37°C, and filtered through a 70-μm cell strainer (Thermo Fisher Scientific). Suspended cells were washed, blocked with 10 μg/ml murine IgG (I5381, Sigma-Aldrich), and stained with isolectin-B4–FITC (L2895, Sigma-Aldrich), anti-CD31-PE (102408, BioLegend), and anti-CD105–APC (120414, BioLegend) antibodies, diluted to 1 μg/ml in PBS with 2.5% FBS. Isolectin-B4/CD31/CD105⁺ cells were sorted using a Beckman Coulter Legacy MoFlo MHS High Speed Cell Sorter and cultured.

Measurement of prostanoids. After 2 days of treatment with vehicle or drugs, blood was collected through the vena cava of terminally anesthetized C57BL/6 mice. For serum, blood was left to clot for 30 minutes at room temperature and centrifuged at 850 g for 15 minutes at 4°C. For plasma, blood collected with ACD buffer (1:10 vol/vol) was centrifuged at 1000 g for 15 minutes at 4°C. B16F10 cells (5 × 10⁴) and/or platelets (50 × 10⁴) were coincubated with 200 μl of whole blood for 10 minutes to remove detached cells and platelets. TXB₂ concentration was measured through a Thromboxane B₂, EIA kit (Cayman Chemical). 6-Keto-PGF₁α concentration was measured in anticoagulated plasma through a 6-keto-PGF₁α, ELISA kit (Enzo Life Sciences).

For ex vivo PGE₂ measurements, whole anticoagulated blood was incubated with 10 μg/ml LPS (Sigma-Aldrich) or saline for 24 hours at 37°C. Plasma was assayed with a PGE₂, ELISA kit (Abcam). For in vivo PGE₂, C57BL/6 mice were injected with 5 mg/kg LPS or saline, and anticoagulated blood was collected through vena cava 4 hours after injection. Plasma...
PGE, was assayed through a PGE<sub>2</sub>-Metabolite EIA kit (PGE<sub>M</sub>, Cayman Chemical), which measures 13,14-dihydro-15-keto-PGA<sub>2</sub> and 13,14-dihydro-15-keto-PGE<sub>2</sub> metabolites.

**Measurement of urinary salicyluric acid.** Urine was collected from restrained C57BL/6 mice 2 weeks after i.v. injection of B16F10 and supplemented with indomethacin (10 μg/ml in DMSO; Sigma-Aldrich). Urine was centrifuged at 10,000 g for 15 minutes at 4°C. Five microliters of urine was mixed with 50 μl 6-methoxysalicylate (internal standard, 10 μM) and 1 ml formic acid (10 mM). To measure salicyluric acid (SUA), a 5-μl sample was injected onto the HPLC (Waters 2695) equipped with a Micromass Quattro Micro Mass Spectrometer (Waters). Separation was achieved using a Kinexen XB (2.6 μm, 2.1 × 50 mm) column maintained at 35°C with eluent A (10 mM formic acid) and eluent B (acetonitrile), using a flow rate of 0.25 ml/min and a gradient of 8%-50% B over 4 minutes. SUA was detected using electrospray in negative mode with tandem mass spectrometry with a capillary voltage of 1.2 V at 194–150 (cone voltage 20 V) and internal standard at 166.9–123 (cone voltage 20 V). Concentrations were calibrated against SUA [N-(2-hydroxybenzoyl)glycine, Apollo Scientific].

**Tumor cell adhesion assay under flow.** A flow-based assay coupled to live cell imaging was used, as described previously (82). 1.5 × 10<sup>4</sup> LMVECs were seeded in μ-Slide IV<sup>©</sup> (Ibidi) and grown to confluence. LMVECs, platelets, and tumor cells were pretreated with vehicle, aspirin (medium dose), SC-560, or NS-398 for 2 hours (LMVECs and platelets) or 30 minutes (platelets) and washed twice. Image acquisition was performed using a Nikon Eclipse TE2000-E microscope (Nikon Plan Fluor 10×/0.30 Ph1 objective) equipped with a Hamamatsu ORCA-ER digital camera (12 frames per minute). Shear-resistant adhesion and association with platelets were quantified from 10 FOVs acquired before and after the increase of shear stress with Imares software.

**Immunofluorescence.** Lungs were perfused with ice-cold PFA 4% and stored in sucrose 25% (Sigma-Aldrich) at 4°C for 2 days. Eighteen-micrometer sections (cryostat microtome, Bright) from snap-frozen lungs were stained for E-selectin (MAI-06506, Thermo Fisher Scientific), VCAM-1 (CBL1300, Millipore), and vWF (ab11713, Abcam) using a TSA biotin amplification system (PerkinElmer).

**Confocal microscopy.** Z-stack images were acquired with an inverted confocal microscope (LSM-710 and LSM-880, Zeiss) equipped with a Plan-Apochromat 20×/0.8 M27 objective. DAPI/CMAC (excitation, 405 nm; emission, 410–513 nm), GFP/Alexa Fluor 488/CMFDA (excitation, 488 nm; emission, 490–653 nm), PE/CMRA (excitation, 543 nm; emission, 548–692 nm), PKH26 (excitation, 561 nm; emission, 568–735 nm), and Alexa Fluor 633 (excitation, 633 nm; emission, 638–747 nm) were detected via a photomultiplier tube array (DAPI, CMAC, 4T1-GFP, Alexa Fluor 488, CMFDA, CMRA, PKH26, Alexa Fluor 633) or a gallium arsenide phosphate (GaAsP) array (PE, Cx3CRI-GFP). Channels were acquired sequentially to minimize bleed-through of emitted light. Stacks of 15–40 slices at 1- to 2-μm intervals from random FOV or tile scans of whole left lung (<10 or <20) were acquired.

**Statistics.** Statistical analysis was performed with GraphPad Prism (version 5.02). D’Agostino and Pearson omnibus normality test was applied to assess data distribution. For normally distributed data, unpaired t-test (2-tailed) or 1-way ANOVA with Tukey’s test or Pearson’s test was used. For non-normally distributed data, Mann-Whitney test, Kruskal-Wallis with Dunn’s multiple-comparisons post hoc test, or Spearman’s test was used. Outliers were identified through Grubb’s’s test (α = 0.05, GraphPad QuickCalc outlier calculator) and excluded. Differences were considered significant with a P value lower than 0.05.

**Study approval.** Animal procedures were performed in accordance with UK Animal law (Scientific Procedures Act 1986), including local ethics approval at the University of Oxford under project license 30/3413.

**Author contributions**

This project was conceived by SL, AMGB, and RJM with the methodology developed by SL, CC, MS, AMGB, ALG, PDA, SS, TDW, AJR, and RJM. The investigations were performed by SL, CC, MS, AMGB, ALG, BM, and KW. Software was developed by PDA and resources provided by PDA, SS, JAW, TDW, AJR, and RJM. Supervision of the project was provided by AMGB, TDW, AJR, and RJM. The original draft was written by SL and RJM.

**Acknowledgments**

We thank Graham Brown and Rhodri Wilson for expert advice and support with microscopy, Michael Stratford for the SUA measurement, and Andrew Worth for cell sorting. We also thank Paul Kinchesh for developing MRI scans and Stuart Gilchrist and John Beech for developing the robot carriage system. RJM is funded by Cancer Research UK grant A1731. SL was the recipient of a Cancer Research UK Oxford Centre DPhil Prize Studentship (BBR7FW00).
