A UNIFIED FRAMEWORK FOR TESTING HIGH DIMENSIONAL PARAMETERS: A DATA-ADAPTIVE APPROACH

BY CHENG ZHOU†, XINSHENG ZHANG‡, WENXIN ZHOU§ AND HAN LIU§

Department of Statistics, Fudan University† and Department of Operation Research and Financial Engineering, Princeton University‡

High dimensional hypothesis test deals with models in which the number of parameters is significantly larger than the sample size. Existing literature develops a variety of individual tests. Some of them are sensitive to the dense and small disturbance, and others are sensitive to the sparse and large disturbance. Hence, the powers of these tests depend on the assumption of the alternative scenario. This paper provides a unified framework for developing new tests which are adaptive to a large variety of alternative scenarios in high dimensions. In particular, our framework includes arbitrary hypotheses which can be tested using high dimensional $U$-statistic based vectors. Under this framework, we first develop a broad family of tests based on a novel variant of the $L_p$-norm with $p \in \{1, \ldots, \infty\}$. We then combine these tests to construct a data-adaptive test that is simultaneously powerful under various alternative scenarios. To obtain the asymptotic distributions of these tests, we utilize the multiplier bootstrap for $U$-statistics. In addition, we consider the computational aspect of the bootstrap method and propose a novel low cost scheme. We prove the optimality of the proposed tests. Thorough numerical results on simulated and real datasets are provided to support our theory.

1. Introduction. Modern data acquisition routinely produces massive datasets in many scientific areas, e.g. genomics, astronomy, functional Magnetic Resonance Imaging (fMRI), and image processing. Effective analysis of such data requires us to test high dimensional parameters ([47, 58, 71, 76, 29, 18]). Though specific methods have been developed to infer high dimensional mean and covariance parameters. It is unclear how to choose the best test when the parameter of interest has a complex structure and the pattern of possible alternative hypothesis is unknown. In particular, we need a unified framework for constructing tests of high dimensional parameters which are simultaneously powerful under a large variety of alternative assumptions. This paper provides such a framework.

Keywords and phrases: High dimensional hypothesis tests, $U$-statistics, multiplier bootstrap methods, data-adaptive tests
1.1. General setup. Our framework considers a generic setup for high dimensional inference. More specifically, let $X = (X_1, \ldots, X_d)^\top$ and $Y = (Y_1, \ldots, Y_d)^\top$ be two $d$-dimensional random vectors independent of each other. $X_1, \ldots, X_{n_1}$ are independent and identically distributed (i.i.d.) random samples from $X$ with $X_k = (X_{k1}, X_{k2}, \ldots, X_{kd})^\top$. Similarly, $Y_1, \ldots, Y_{n_2}$ are i.i.d. random samples from $Y$ with $Y_k = (Y_{k1}, Y_{k2}, \ldots, Y_{kd})^\top$. We set $X = \{X_1, \ldots, X_{n_1}\}$, $Y = \{Y_1, \ldots, Y_{n_2}\}$, and

$$
\hat{u}_{1,s} = \left(\frac{n_1}{m}\right)^{-1} \sum_{1 \leq k_1 < \cdots < k_m \leq n_1} \Phi_s(X_{k_1}, \ldots, X_{k_m}),
$$

$$
\hat{u}_{2,s} = \left(\frac{n_2}{m}\right)^{-1} \sum_{1 \leq k_1 < \cdots < k_m \leq n_2} \Phi_s(Y_{k_1}, \ldots, Y_{k_m}),
$$

(1.1)

where $s = 1, \ldots, q$, and $\Phi_s$ is a $m$-order symmetric kernel function. We assume that $\Phi_s$ is symmetric and that each kernel function is of the same order $m$ only for notational simplicity.\(^1,2\)

We then define two $U$-statistic based vectors as

$$
\hat{u}_1 := (\hat{u}_{1,1}, \hat{u}_{1,2}, \ldots, \hat{u}_{1,q})^\top \quad \text{and} \quad \hat{u}_2 := (\hat{u}_{2,1}, \hat{u}_{2,2}, \ldots, \hat{u}_{2,q})^\top.
$$

(1.2)

We use $u_\gamma$ to denote the expectation of $\hat{u}_\gamma$, i.e., $u_\gamma = (u_{\gamma,1}, u_{\gamma,2}, \ldots, u_{\gamma,q})^\top$ with $u_{\gamma,s} = \mathbb{E}[\hat{u}_{\gamma,s}]$ for $\gamma = 1, 2$ and $s = 1, \ldots, q$. We are interested in testing the hypotheses:

(i) (One-sample problem) For a given $u_0 \in \mathbb{R}^q$,

$$
H_0 : u_1 = u_0 \quad \text{v.s.} \quad H_1 : u_1 \neq u_0;
$$

(1.3)

(ii) (Two-sample problem)

$$
H_0 : u_1 = u_2 \quad \text{v.s.} \quad H_1 : u_1 \neq u_2.
$$

(1.4)

We consider the high dimensional setting that $d/n$ (or $q/n$) does not necessarily go to zero. These two kinds of hypotheses are quite general and include most existing studies as special cases.

\(^1\)If $\Phi_s$ is an asymmetric kernel function, it gives a $U$-statistic $\hat{u}_{1,s} = \frac{1}{m} \left(\frac{n_1}{m}\right)^{-1} \sum \Phi_s(x_{\ell_1}, \ldots, x_{\ell_m})$, where the summation is over all permutations of distinct elements $\{\ell_1, \ldots, \ell_m\}$ from $\{1, \ldots, n_1\}$. By setting $\Phi_s^0(x_1, \ldots, x_m) = (m!)^{-1} \sum \Phi_s(x_{k_1}, \ldots, x_{k_m})$, where the summation is over all permutations of $\{1, \ldots, m\}$, we rewrite $\hat{u}_{1,s}$ as a $U$-statistic with a symmetric kernel $\Phi_s^0$. For $Y$, we can rewrite $\hat{u}_{2,s}$ as a $U$-statistic with a symmetric kernel similarly.

\(^2\) If $\{\Phi_s\}_{s=1,\ldots,q}$ have different kernel orders, we require that the kernel orders are uniformly bounded.
1.2. Special cases and applications. In this section, we provide several special cases of the above general testing problem.

- Matrix-based one-sample test:

\[
H_0 : U_1 = I_d \quad \text{v.s.} \quad H_1 : U_1 \neq I_d,
\]

where $U_1$’s entries are estimated by $U$-statistics and $I_d$ is an identity matrix of size $d$. The hypothesis (1.5) is often used to infer the independence of random variables. This problem plays a fundamental role in many fields including multiple testing ([9]), naive Bayes classification ([69, 32]), and independent component analysis([25]). Under the Gaussian setting, testing (1.5) with $U_1$ as covariance matrix is well studied both in low ([60, 57, 1]) and high ([45, 42, 10, 62, 3, 22, 12, 43, 17]) dimensions. Moreover, [42, 48, 75, 51, 16, 12, 65] consider the high dimensional independence test under more general distribution. Considering robustness, rank-based $U$-statistics such as Kendall’ s tau and Spearman’s rho are introduced to describe the dependence of random variables. As for their definitions and basic theoretical properties, we refer to the book [46]. Recently, [35, 6] study how to utilize general $U$-statistics for high dimensional independence test.

- Matrix-based two-sample test:

\[
H_0 : U_1 = U_2 \quad \text{v.s.} \quad H_1 : U_1 \neq U_2,
\]

where $U_1$ and $U_2$ are matrices such that their entries are estimated by $U$-statistics. The hypothesis (1.6) is often used before the discriminant analysis ([1, 64, 13, 55, 33, 54, 36]) to simplify the test statistics. For low dimensional two-sample covariance matrix test, we refer its theoretical properties to [1]. In recent years, [63, 68, 49, 14, 21] study how to perform the two-sample covariance matrix test in high dimensions. Moreover, [46, 35, 6, 74] consider how to use general $U$-statistics to replace covariance coefficients.

- Means test:

(i) (One-sample problem)

\[
H_0 : \mu_1 = 0 \quad \text{v.s.} \quad H_1 : \mu_1 \neq 0;
\]

(ii) (Two-sample problem)

\[
H_0 : \mu_1 = \mu_2 \quad \text{v.s.} \quad H_1 : \mu_1 \neq \mu_2;
\]
where $\mu_1$ and $\mu_2$ are mean vectors of $X$ and $Y$. Testing the mean vector is a special case of (1.7) and (1.8). The testing of mean values is very fundamental. We refer their low dimensional properties to [1]. Recently, a large amount of literature work on high dimensional means test ([4, 67, 66, 22, 15, 20]).

For (1.5) and (1.6), we can convert the matrix into a column vector by vectorization to obtain equivalent tests with the same form as (1.7) or (1.8). Therefore, (1.5) and (1.6) fall in our framework.

Testing high dimensional $U$-statistic parameters also has many important practical applications. For example, in gene selection, we use it to detect gene differences [37, 39, 38, 14, 15] or rare variants [8, 50, 70, 47, 58] between the diseased and non-diseased population. In finance, we use it to detect anomalies ([19]) and test the market efficiency ([28, 30, 31]).

1.3. Background and existing work. In the low dimensional setting with $d < n$ fixed, the Hotelling’s $T^2$ test enjoys certain kind of optimality and has been widely used. To test two-sample mean vectors, the Hotelling’s $T^2$ is defined as

$$T^2 = \frac{n_1 n_2}{n_1 + n_2} (\overline{X} - \overline{Y})^\top S_{1,2}^{-1} (\overline{X} - \overline{Y}),$$

where $\overline{X} = n_1^{-1} \sum_{k=1}^{n_1} X_k$, $\overline{Y} = n_2^{-1} \sum_{k=1}^{n_2} Y_k$, and

$$S_{1,2} = \frac{1}{n_1 + n_2 - 2} \left( \sum_{k=1}^{n_1} (X_k - \overline{X})(X_k - \overline{X})^\top + \sum_{k=1}^{n_2} (Y_k - \overline{Y})(Y_k - \overline{Y})^\top \right).$$

As for the limiting distribution, large and moderate deviations of Hotelling’s $T^2$, we refer to [1, 27, 52].

In the high dimensional setting, many tests have been proposed to test high dimensional vectors and matrices. These tests fall in two categories: the $L_2$-type versus $L_\infty$-type tests. Specifically, for (1.7) and (1.8), the $L_2$-type tests are based on $\|A(u_1 - u_0)\|_2$ or $\|A(u_1 - u_2)\|_2$, and the $L_\infty$-type tests are based on $\|A(u_1 - u_0)\|_\infty$ or $\|A(u_1 - u_2)\|_\infty$ for some operator $A$. On one hand, the $L_2$-type tests [4, 63, 66, 68, 22, 49] aim to detect relatively dense signals, as the $L_2$-norm accumulates small deviations of all entries. On the other hand, the $L_\infty$-type tests [14, 15] are more sensitive to sparse signals, where some strong perturbations exist on a small number of entries. [52, 14, 15] illustrate that the $L_\infty$-type tests are reasonably more powerful than the $L_2$-type tests and enjoy certain kind of optimality when the alternative is sparse.
1.4. Our contributions. Theoretically, there is no uniformly most powerful test under different scenarios of the alternatives ([26]). Therefore, depending on the unknown truth of alternatives, a given and fixed test may or may not be powerful. In this paper, we aim to develop a broad family of tests such that at least one of them is powerful enough in a given situation. We then combine these tests to obtain a data-adaptive test that will maintain high power across a wide range of alternative scenarios. We develop our family of tests based on a new family of adjusted $L_p$-norms with $p = 1, 2, \ldots, \infty$, so that there is at least one test in our family is powerful no matter the signal is dense or sparse. The limiting distribution of the data-adaptive test is very complex that we cannot obtain its explicit form. Therefore, we use the bootstrap method to approximate the limiting distribution, so that we can obtain the critical value and valid $P$-value of the test.

More specifically, to obtain a better approximation in the high dimensional setting, we adjust $L_p$-norm while building the test statistics. In detail, we introduce it as follows.

**Definition 1.1.** For $v = (v_1, \ldots, v_d) \top \in \mathbb{R}^d$, we define $\|v\|_{(s_0, p)} := \left(\sum_{j=d-s_0+1}^{d} (v(j))^p\right)^{1/p}$, where $v(1), v(2), \ldots, v(d)$ are the order statistics of $|v_1|, \ldots, |v_d|$ with $0 \leq v(1) \leq v(2) \leq \ldots \leq v(d)$.

By this definition, for any positive integer $s_0$, we have $\|v\|_{(s_0, \infty)} = \|v\|_\infty$, where $\|v\|_\infty = \max_{j=1, \ldots, d} |v_j|$. Moreover, the following proposition shows that $\| \cdot \|_{(s_0, p)}$ is a norm for any $1 \leq p \leq \infty$.

**Proposition 1.** For any $1 \leq p \leq \infty$, $\| \cdot \|_{(s_0, p)}$ is a norm on $\mathbb{R}^d$.

The detailed proof of Proposition 1 is in Appendix B.1 of supplementary materials. In this paper, we assume $1 \leq p \leq \infty$ to make $\| \cdot \|_{(s_0, p)}$ a norm. Therefore, similarly to $L_p$-norm, we can call $\|v\|_{(s_0, p)}$ the $(s_0, p)$-norm of $v$ in this paper. To construct the above family of tests, we use the $(s_0, p)$-norm as the adjusted $L_p$-norm. More details on this testing procedure is in Section 2. This paper has four major contributions:

- First, we introduce a new family of tests based on the $(s_0, p)$-norm. As is shown in the simulation experiment of Section 4, the power of traditional $L_p$-norm based test decreases tremendously (especially for small $p$) as $q \to \infty$. The reason is that the $L_p$-norm with small $p$ is easy to accumulate the noise of all entries. Therefore, we introduce $s_0$ to increase the signal-noise ratio of test statistics. The introduction of $s_0$ is also crucial in establishing our theoretical results for high
dimensional multiplier bootstrap. Moreover, we obtain the required scaling between \( s_0, p, q, \) and \( n \) for the proposed bootstrap methods.

- Secondly, as it is hard to obtain the joint distribution of test statistics with various \((s_0, p)\)-norm, we use the multiplier bootstrap method to obtain its asymptotic distribution. In low dimensions, this bootstrap method is well studied for both the sum of random variables \([61, 53, 59, 7]\) and \(U\)-statistics \([44, 2, 56, 41, 40, 34]\). In high dimensions, the multiplier bootstrap is also useful for approximating the sum of random vectors \([23]\). Motivated by these results, we generalize multiplier bootstrap method for \(U\)-statistics to the high dimensional setting with theoretical guarantees.

- Thirdly, for adapting to the possible alternatives, we propose a new approach to combine these \((s_0, p)\)-norm based tests. Our combined test automatically chooses the most powerful test within the chosen combination according to the data. Therefore, we call this test the data-adaptive combined test. However, to obtain the \(P\)-value for the combined test, we originally need a double-loop bootstrap procedure, which suffers from high computational cost. To avoid this, we propose a novel computationally efficient scheme which generates nonindependent bootstrap samples. We also provide theoretical guarantees for this new bootstrap scheme in the high dimensional setting.

- Finally, combining the developed theory for the proposed methods and exiting lower bounds in the literature, we present that our methods are rate-optimal in many settings.

1.5. Notation. We set \( \|v\|_p \) as the \(L_p\)-norm of a vector \( v = (v_1, \ldots, v_d) \top \in \mathbb{R}^d \). We denote the spherical surface in \( \mathbb{R}^d \) by \( S^{d-1} := \{ v \in \mathbb{R}^d : \|v\|_2 = 1 \} \).

For two sequences of real numbers \( \{a_n\} \) and \( \{b_n\} \), we write \( a_n = O(b_n) \) if there exists a constant \( C \) such that \( |a_n| \leq C|b_n| \) holds for all sufficiently large \( n \), write \( a_n = o(b_n) \) if \( a_n / b_n \to 0 \), and write \( a_n \asymp b_n \) if there exist constants \( C \geq c > 0 \) such that \( c|b_n| \leq |a_n| \leq C|b_n| \) for all sufficiently large \( n \). For a sequence of random variables \( \{\xi_1, \xi_2, \ldots\} \), we use \( \xi_n \to \xi \) to denote that the sequence \( \{\xi_n\} \) converges in probability towards \( \xi \) as \( n \to \infty \). For simplicity, we also use \( \xi_n = o_p(1) \) to denote \( \xi_n \to 0 \).

1.6. Paper organization. The rest of this paper is organized as follows. In Section 2 we propose the new testing procedures: the individual \((s_0, p)\)-norm based test and the data-adaptive combined test. In Section 3, we develop a theory to analyze the size and power of the proposed tests. Section 4 provides some numerical results on simulated data to justify our proposed methods' size and power. In Section 5, we discuss some potential future work. Sup-
plementary materials provide both proofs and additional numerical results on both simulated and real data.

2. Methodology. This section introduces the \((s_0, p)\)-norm based individual tests and the data-adaptive combined test for testing high dimensional \(U\)-statistic based parameters. We also introduce how to exploit the multiplier bootstrap method to obtain the critical values and \(P\)-values for both individual and combined tests. In the following, we introduce individual tests based on the \((s_0, p)\)-norm in Section 2.1 and the data-adaptive combined test in Section 2.2.

2.1. Individual tests based on the \((s_0, p)\)-norm. We introduce the \((s_0, p)\)-norm based tests which are basic components of the data-adaptive combined test. First, we explain the construction motivation in Section 2.1.1 and describe the test statistics in Section 2.1.2. We then introduce bootstrapping scheme for \(U\)-statistics in high dimensions in Section 2.1.3 and use it to obtain critical values and \(P\)-values for the proposed tests.

2.1.1. Motivation of the construction of the \((s_0, p)\)-norm. We first introduce the motivation of the proposed individual tests. In the existing literature, there are two types of tests (\(L_2\)-type and \(L_\infty\)-type tests) to test high dimensional vectors or matrices. The \(L_2\)-type tests are sensitive to dense signals and the \(L_\infty\)-type tests are sensitive to sparse signals. Therefore, the performance of these tests depends on the pattern of possible alternatives. If such pattern is unknown, it is more desirable to construct a data-adaptive test which is simultaneously powerful under various alternative scenarios. For this, we need to construct a family of versatile tests so that for a given alternative at least one test within the family is powerful. Inspired by the existing \(L_2\)-type and \(L_\infty\)-type tests, we build the test family based on the \(L_p\)-norm. Importantly, as \(p\) increases, the \(L_p\)-norm puts more weight on the larger entries while gradually ignoring the remaining smaller entries. As \(p \to \infty\), we have \(\|v\|_p \to \|v\|_\infty\) for any \(v \in \mathbb{R}^d\), where \(\|v\|_\infty\)'s value only depends on the largest entry of \(v\). More generally, as \(p\) increases, we put more weight on the larger entries, eventually realizing the \(L_\infty\)-type test. Hence, by properly choosing \(p\) from the proposed test family, there exists at least one test within the family that is powerful in each alternative situation.

However, it is problematic to directly use the \(L_p\)-norm \((p < \infty)\) to construct the test statistics in high dimensions. For example, when \(d/n \not\to 0\), Hotelling’s \(T^2\) test \((L_2\)-type) performs poorly, as the Pearson’s sample covariance matrices no longer converge to their population counterparts under the spectral norm \((5)\). For high dimensional testing problems, we need to
adjust the test statistics or make structured assumptions on the population covariance matrix to obtain better asymptotic distributions of the test statistics. We face the same problem while using \( L_p \)-norm \( (p < \infty) \) to construct the test statistics. Hence, to avoid making unnecessary assumptions on the covariance structure of the random vector, we introduce the \((s_0, p)\)-norm to adjust the original \( L_p \)-norm. As is shown by numerical simulations in Section 4, the \( L_p \)-norm based test with small \( p \) has significant power loss when the dimension of the parameter of interest \( q \to \infty \). The introduction of \( s_0 \) can boost the power of \( L_p \)-norm based test especially for small \( p \). More specifically, when \( p \) is small, the \( L_p \)-norm accumulates noise from all the entries, which leads to significant power loss. By exploiting the \((s_0, p)\)-norm, we can enhance the signal-noise ratio for the obtained test statistics. When \( p \) is large, the choice of \( s_0 \) becomes less critical. In theory, for the bootstrap scheme to work properly under any \( 1 \leq p \leq \infty \), we require that \( s_0^2 \log(nq) = O(n^\delta) \) holds for some \( 0 < \delta < 1/7 \). Therefore, \( s_0 \) can also go to the infinity as \( n \to \infty \). By simulation, \( s_0 \) close to \( s \), which is the true unknown number of entries violating \( H_0 \), is preferable. More details on the choice of \( s_0 \) are provided in Section 3 and 4.

### 2.1.2. The \((s_0, p)\)-norm based test statistics

Before presenting the test statistics, we first introduce the following jackknife variance estimator for the \( U \)-statistic \( \hat{u}_{\gamma, s} \) defined in (1.1) with \( \gamma = 1, 2 \) and \( s = 1, 2, \ldots, q \). As \( m \geq 2 \), we define

\[
(2.1) \quad \hat{v}_{1,s} = m^2 n_1^{-1} \sum_{k=1}^{n_1} (Q_{1k,s} - \hat{u}_{1,s})^2, \quad \hat{v}_{2,s} = m^2 n_2^{-1} \sum_{k=1}^{n_2} (Q_{2k,s} - \hat{u}_{2,s})^2,
\]

where we set

\[
Q_{1k,s} := \left( n_{1-1} \right)_m^{-1} \sum_{1 \leq \ell_1 < \cdots < \ell_m \leq n_1 \atop \ell_j \neq k, j = 1, \ldots, m-1} \Phi_s(X_k, X_{\ell_1}, \ldots, X_{\ell_{m-1}}),
\]

\[
Q_{2k,s} := \left( n_{2-1} \right)_m^{-1} \sum_{1 \leq \ell_1 < \cdots < \ell_m \leq n_2 \atop \ell_j \neq k, j = 1, \ldots, m-1} \Phi_s(Y_k, Y_{\ell_1}, \ldots, Y_{\ell_{m-1}}).
\]

We use \( \hat{v}_{\gamma,s} \) to estimate the variance of \( \sqrt{n_1} \hat{u}_{\gamma,s} \). Therefore, \( \hat{v}_{\gamma,s}/n_1 \) is the variance estimator for \( \hat{u}_{\gamma,s} \). As \( m = 1 \), \( \hat{u}_{\gamma,s} \) and \( \hat{v}_{\gamma,s} \) are reduced to

\[
(2.3) \quad \left\{ \begin{array}{ll}
\hat{u}_{1,s} = n_1^{-1} \sum_{k=1}^{n_1} \Phi_s(X_k), & \hat{v}_{1,s} = n_1^{-1} \sum_{k=1}^{n_1} (\Phi_s(X_k) - \hat{u}_{1,s})^2, \\
\hat{u}_{2,s} = n_2^{-1} \sum_{k=1}^{n_2} \Phi_s(Y_k), & \hat{v}_{2,s} = n_2^{-1} \sum_{k=1}^{n_2} (\Phi_s(Y_k) - \hat{u}_{2,s})^2.
\end{array} \right.
\]
After introducing these notations, we present our \((s_0,p)\)-norm based test statistics. For this, we define \(W = (W_1, \ldots, W_q)\) and \(N = (N_1, \ldots, N_q)\), where we set \(W_s\) and \(N_s\) as

\[
W_s := \left(\hat{u}_{1,s} - u_{0,s}\right)/\sqrt{\hat{v}_{1,s}/n_1}, \\
N_s := \left(\hat{u}_{1,s} - \hat{u}_{2,s}\right)/\sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2}.
\]

(2.4)

For the one-sample problem in (1.7), we propose the test statistic \(W_{(s_0,p)} := \|W\|_{(s_0,p)}\). Similarly, for the two-sample problem in (1.8), we propose the test statistic \(N_{(s_0,p)} := \|N\|_{(s_0,p)}\). Throughout this paper, if not specially specified, we require \(1 \leq p \leq \infty\) to make \(\|\cdot\|_{(s_0,p)}\) a norm, which is also required by the theory.

2.1.3. Bootstrap procedure for the asymptotic distribution. In the high dimensional setting, [23] introduce the multiplier bootstrap method for the sum of independent random vectors. In detail, let \(Z_1, \ldots, Z_n\) be independent random vectors in \(\mathbb{R}^d\) with \(Z_k = (Z_{k1}, \ldots, Z_{kd})^\top\) and \(E[Z_k] = 0\) for \(k = 1, \ldots, n\). Let \(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n\) be independent standard normal random variables, the multiplier bootstrap sample for \(Z_1, \ldots, Z_n\) is \(\varepsilon_1 Z_1, \ldots, \varepsilon_n Z_n\). The bootstrap sample for the sample mean \(n^{-1}\sum_{k=1}^{n} Z_k\) then becomes \(n^{-1}\sum_{k=1}^{n} \varepsilon_k Z_k\). To fully utilize this result, we use multiplier bootstrap scheme for for high dimensional U-statistics. In detail, we generate independent samples \(\varepsilon_{1,1}^b, \ldots, \varepsilon_{1,n_1}^b\) and \(\varepsilon_{2,1}^b, \ldots, \varepsilon_{2,n_2}^b\) from \(\varepsilon \sim N(0, 1)\) for \(b = 1, \ldots, B\) and set

\[
\tilde{u}_{1,s}^b = \left(\frac{n_1}{m}\right)^{-1} \sum_{1 \leq k_1 < \cdots < k_m \leq n_1} \varepsilon_{1,k_1}^b + \cdots + \varepsilon_{1,k_m}^b \left(\Phi_s(X_{k_1}, \ldots, X_{k_m}) - \hat{u}_{1,s}\right), \\
\tilde{u}_{2,s}^b = \left(\frac{n_2}{m}\right)^{-1} \sum_{1 \leq k_1 < \cdots < k_m \leq n_2} \varepsilon_{2,k_1}^b + \cdots + \varepsilon_{2,k_m}^b \left(\Phi_s(Y_{k_1}, \ldots, Y_{k_m}) - \hat{u}_{2,s}\right).
\]

Correspondingly, we set \(\hat{u}_{1,s}^b = (\hat{u}_{1,1}^b, \ldots, \hat{u}_{1,q}^b)\) for \(\gamma = 1, 2\). After introducing \(\hat{u}_{1,s}^b\), we define \(W^b = (W_1^b, \ldots, W_q^b)\) and \(N^b = (N_1^b, \ldots, N_q^b)\), where

\[
W_s^b = \hat{u}_{1,s}^b / \sqrt{\hat{v}_{1,s}/n_1}, \quad N_s^b = (\hat{u}_{1,s}^b - \hat{u}_{2,s}^b) / \sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2}.
\]

(2.5)

Bootstrap samples become \(\{N_s^b\}_{b=1}^{B}\) and \(\{W_s^b\}_{b=1}^{B}\) with

\[
W_{(s_0,p)}^b = \|W^b\|_{(s_0,p)} \quad \text{and} \quad N_{(s_0,p)}^b = \|N^b\|_{(s_0,p)}.
\]

(2.6)
Given the significance level $\alpha$ and the bootstrap samples, we set the critical values of $W(\mathbf{s}_0, p)$ and $N(\mathbf{s}_0, p)$ as

$$\tilde{t}_{\alpha,(\mathbf{s}_0, p)}^W = \inf \left\{ t \in \mathbb{R} : \frac{1}{B} \sum_{b=1}^{B} \mathbb{I}\{W^b(\mathbf{s}_0, p) \leq t\} > 1 - \alpha \right\},$$

$$\tilde{t}_{\alpha,(\mathbf{s}_0, p)}^N = \inf \left\{ t \in \mathbb{R} : \frac{1}{B} \sum_{b=1}^{B} \mathbb{I}\{N^b(\mathbf{s}_0, p) \leq t\} > 1 - \alpha \right\}.$$

Therefore, we obtain the $(\mathbf{s}_0, p)$-norm based tests for (1.7) and (1.8) as

$$T_{\alpha,(\mathbf{s}_0, p)}^W := \mathbb{I}\{W(\mathbf{s}_0, p) \geq \tilde{t}_{\alpha,(\mathbf{s}_0, p)}^W\}, \quad T_{\alpha,(\mathbf{s}_0, p)}^N := \mathbb{I}\{N(\mathbf{s}_0, p) \geq \tilde{t}_{\alpha,(\mathbf{s}_0, p)}^N\}.$$  

We reject $H_0$ of (1.7) if and only if $T_{\alpha,(\mathbf{s}_0, p)}^W = 1$ and reject $H_0$ of (1.8) if and only if $T_{\alpha,(\mathbf{s}_0, p)}^N = 1$. Accordingly, we estimate $W(\mathbf{s}_0, p)$ and $N(\mathbf{s}_0, p)$’s oracle $P$-values $P_{\alpha,(\mathbf{s}_0, p)}^W$ and $P_{\alpha,(\mathbf{s}_0, p)}^N$ by

$$\hat{P}_{(\mathbf{s}_0, p)}^W = (B + 1)^{-1} \sum_{b=1}^{B} \mathbb{I}\{W^b(\mathbf{s}_0, p) > W(\mathbf{s}_0, p)\},$$

$$\hat{P}_{(\mathbf{s}_0, p)}^N = (B + 1)^{-1} \sum_{b=1}^{B} \mathbb{I}\{N^b(\mathbf{s}_0, p) > N(\mathbf{s}_0, p)\}.$$  

Therefore, given a significance level $\alpha$, we reject $H_0$ of (1.7) if and only if $\hat{P}_{(\mathbf{s}_0, p)}^W \leq \alpha$ and reject $H_0$ of (1.8) if and only if $\hat{P}_{(\mathbf{s}_0, p)}^N \leq \alpha$.

2.2. Data-adaptive combined test. We now introduce the data-adaptive combined test. In Section 2.2.1, we present the test procedure. In Section 2.2.2, we introduce a double-loop bootstrap procedure to obtain the $P$-value of the data-adaptive test. To reduce the expensive computation cost of the double-loop bootstrap procedure, in Section 2.2.3 we introduce a low cost bootstrap procedure which obtains nonindependent bootstrap samples. The theory of this new low cost bootstrap procedure is provided in Section 3.3.

2.2.1. Test statistics. $W(\mathbf{s}_0, p)$ and $N(\mathbf{s}_0, p)$ have different powers for different $p$ and alternative scenarios. For example, $W(\mathbf{s}_0, \infty)$ and $N(\mathbf{s}_0, \infty)$ are sensitive to large perturbations on a small number of entries of $\mathbf{u}_1 - \mathbf{u}_0$ and $\mathbf{u}_1 - \mathbf{u}_2$. Moreover, $W(\mathbf{s}_0, 2)$ and $N(\mathbf{s}_0, 2)$ are sensitive to small perturbations on a large number of entries of $\mathbf{u}_1 - \mathbf{u}_0$ and $\mathbf{u}_1 - \mathbf{u}_2$. We aim to combine these tests to construct a data-adaptive test which is simultaneously powerful under different alternatives.
For the one-sample problem, as small \( P \)-values of \( W(s_0,p) \) lead to the rejection of \( H_0 \) in (1.7), we construct the data-adaptive test statistic \( W_{ad} \) by taking the minimum of \( P \)-values of all individual tests, i.e.,

\[
W_{ad} = \min_{p \in \mathcal{P}} \hat{P}^W(s_0,p),
\]

where \( \mathcal{P} \subset \{1, 2, \ldots, \infty\} \) is a candidate set of \( p \). A bootstrap procedure to obtain \( W_{ad} \) is described in Algorithm 1. For the two-sample problem in (1.8), we construct the data-adaptive test statistic \( N_{ad} \) as

\[
N_{ad} = \min_{p \in \mathcal{P}} \hat{P}^N(s_0,p).
\]

Throughout this paper, we require that \( \#(\mathcal{P}) < \infty \) is a fixed constant, which is also required by the theory and discussed in Section 3.3. If the alternative pattern is unknown, we recommend using the balanced \( \mathcal{P} \) including both small and large values of \( p \in [1, \infty] \). For example, \( \mathcal{P} = \{1, 2, \ldots, 5, \infty\} \) is used in the later simulation experiments. If the alternative pattern is known, we can boost the power of the data-adaptive combined test by choosing \( \mathcal{P} \) accordingly. For example, for possible sparse alternatives, \( \mathcal{P} \) should consist of large values of \( p \).

\State \( W_{ad} = \min_{p \in \mathcal{P}} \hat{P}^W(s_0,p) \).
\EndFor{}
\end{algorithmic}
\end{algorithm}

2.2.2. \textit{Double-loop bootstrap procedure.} We present how to obtain \( P \)-value of \( W_{ad} \). By setting \( F_{W_{ad}}(x) \) as the distribution function of \( W_{ad} \), \( W_{ad} \)’s oracle \( P \)-value becomes \( F_{W_{ad}}(W_{ad}) \). As \( F_{W_{ad}}(x) \) is unknown, we need to
use the bootstrap method to estimate it, which leads to a double-loop bootstrap procedure. In the outer loop, by Algorithm 1 we obtain the bootstrap samples for $W_{(s_0,p)}$, i.e., $\{W_{(s_0,p)}^1, \ldots, W_{(s_0,p)}^B\}$. In the inner loop, for each $b \in \{1, \ldots, B\}$, we use Algorithm 2 to obtain bootstrap samples for $W_{(s_0,p)}^b$, i.e., $\{W_{(s_0,p)}^{b,1}, \ldots, W_{(s_0,p)}^{b,L}\}$, and construct the bootstrap samples for $W_{ad}$ as

$$W_{ad}^b = \min_{p \in P} \frac{\sum_{\ell=1}^L I\{W_{(s_0,p)}^{b,\ell} > W_{(s_0,p)}^b\}}{L + 1}$$

for $b = 1, \ldots, B$.

With the bootstrap samples, we can estimate the oracle $P$-value of $W_{ad}$ by

$$\frac{1}{B + 1} \left( \sum_{b=1}^B I\{W_{ad}^b \leq W_{ad}\} + 1 \right).$$

Figure 1 illustrates this double-loop bootstrap method. By this double-loop bootstrap procedure, to guarantee the independence of $W_{ad}^1, \ldots, W_{ad}^B$, we to tally need $LB + B$ samples from (2.1.3), which is computationally expensive when $L$ and $B$ are large.

Algorithm 2 A double-loop bootstrap procedure to obtain bootstrap samples of $W_{ad}$

**Input:** $X$ and $W_{(s_0,p)}^1, \ldots, W_{(s_0,p)}^B$ for $p \in P$.

**Output:** $W_{ad}^1, \ldots, W_{ad}^B$.

1. procedure
2. for $b \leftarrow 1$ to $B$ do
3. for $\ell \leftarrow 1$ to $L$ do
4. Sample independent standard normal random variables $\{\varepsilon_{1,1,b,\ell}, \ldots, \varepsilon_{1,n_1,b,\ell}\}$.
5. $\tilde{u}_{1,s} = (n_1)^{-1} \sum_{1 \leq k_1 < \cdots < k_m \leq n_1} (\varepsilon_{1,k_1,b,\ell} + \cdots + \varepsilon_{1,k_m,b,\ell}) (\Phi(s, \ldots, X_{k_m}) - \tilde{u}_{1,s})$.
6. $W_{(s_0,p)}^{b,\ell} = \tilde{u}_{1,s}/\sqrt{\tilde{v}_{1,s}/n_1}$ for $s = 1, \ldots, q$.
7. for $p \in P$ do
8. $W_{(s_0,p)}^{b,\ell} = ||W_{(s_0,p)}^{b,\ell}||$ with $W_{(s_0,p)}^{b,\ell} = (W_{1,b,\ell}^{b,\ell}, \ldots, W_{q,b,\ell}^{b,\ell})$.
9. end for
10. $\hat{P}_{W_{(s_0,p)}}^b = \sum_{\ell=1}^L I\{W_{(s_0,p)}^{b,\ell} > W_{(s_0,p)}^b\}/(L + 1)$ for $p \in P$.
11. $W_{ad}^b = \min_{p \in P} \hat{P}_{W_{(s_0,p)}}^b$.
12. end for
13. end procedure

2.2.3. A low cost bootstrap procedure. To handle the computational bottleneck of the double-loop bootstrap, we propose to replace Algorithm 2 with Algorithm 3, which is computationally more efficient but obtains non-independent bootstrap samples for $W_{ad}$, denoted as $\{W_{ad}^1, \ldots, W_{ad}^B\}$.
In detail, in Algorithm 1 by (2.1.3), (2.5), and (2.6) we generate bootstrap samples for $W^{(s_0,p)}$, i.e., $W^1^{(s_0,p)}, \ldots, W^B^{(s_0,p)}$. To avoid the double-loop bootstrap procedure, we need to more effectively utilize the generated bootstrap samples $W^1^{(s_0,p)}, \ldots, W^B^{(s_0,p)}$. For this, we set

$$\hat{P}^{b,W}_{(s_0,p)} = \frac{\sum_{b=1}^{B} \mathbb{I}\{W^b_{(s_0,p)} > W^0_{(s_0,p)}\}}{B}$$

for $b = 1, \ldots, B$ and $p \in \mathcal{P}$.

We use $W^{b}_{ad'} = \min_{p \in \mathcal{P}} \hat{P}^{b,W}_{(s_0,p)}$ as the bootstrap sample for $W_{ad}$, and estimate the oracle $P$-value by

$$(2.11) \quad \hat{P}^W_{ad} = \frac{\sum_{b=1}^{B} \mathbb{I}\{W^b_{ad'} \leq W_{ad}\}}{B + 1}.$$ 

The samples $W^1_{ad'}, \ldots, W^B_{ad'}$ are nonindependent. However, we can prove that they are asymptotically independent as $n_1, B \to \infty$, which plays a pivotal role in proving the consistency of $\hat{P}^W_{ad}$.

Figure 2 illustrates the process of the low cost bootstrap procedure. To obtain the $P$-value of $W_{ad}$, we don’t need to generate new bootstrap samples. In total, to perform the data-adaptive test we only need to generate $B$ bootstrap samples from (2.1.3).

We similarly deal with the two-sample problem. By generating bootstrap
samples for \( N_{(s_0,p)} \), i.e., \( N_{(s_0,p)}^1, \ldots, N_{(s_0,p)}^B \) and setting

\[
\hat{P}_{b,N}^{(s_0,p)} = \frac{\sum_{b_1 \neq b} 1 \{ N_{(s_0,p)}^{b_1} > N_{(s_0,p)}^b \} }{B} \quad \text{for } b = 1, \ldots, B \text{ and } p \in \mathcal{P},
\]

we use \( N_{ad}^b = \min_{p \in \mathcal{P}} \hat{P}_{b,N}^{(s_0,p)} \) as the bootstrap sample of \( N_{ad} \). Therefore, we can similarly estimate the oracle \( P \)-value of \( N_{ad} \) by

\[
\hat{P}_{ad}^N = \frac{\left( \sum_{b=1}^B 1 \{ N_{ad'}^b \leq N_{ad} \} \right) + 1}{B + 1}.
\]

With the estimated \( P \)-values of the data-adaptive tests \( W_{ad} \) and \( N_{ad} \), given significance level \( \alpha \), we reject \( H_0 \) of (1.7) if and only if \( \hat{P}_{ad}^W \leq \alpha \) and reject \( H_0 \) of (1.8) if and only if \( \hat{P}_{ad}^N \leq \alpha \). Therefore, we set

\[
T_{ad}^W = 1 \{ \hat{P}_{ad}^W \leq \alpha \} \quad \text{and} \quad T_{ad}^N = 1 \{ \hat{P}_{ad}^N \leq \alpha \}.
\]

Algorithm 3 A low cost bootstrap procedure

Input: \( \mathcal{X} \) and \( W_{(s_0,p)}^1, \ldots, W_{(s_0,p)}^B \) for \( p \in \mathcal{P} \).
Output: \( W_{ad}^1, \ldots, W_{ad}^B \).

1: procedure
2: for \( b \leftarrow 1 \) to \( B \) do
3: for \( p \) in \( \mathcal{P} \) do
4: \( \hat{P}_{b,W}^{(s_0,p)} = \frac{\sum_{b_1 \neq b} 1 \{ W_{(s_0,p)}^{b_1} > W_{(s_0,p)}^b \} }{B} \)
5: end for
6: \( W_{ad}^b = \min_{p \in \mathcal{P}} \hat{P}_{b,W}^{(s_0,p)} \)
7: end for
8: end procedure

Fig 2. Flowchart for the low cost bootstrap procedure with low computation cost and total number of generated standard normal random variables.
Remark 2.1. To construct test statistics $W_{(s_0,p)}$ and $N_{(s_0,p)}$, we normalize $\hat{u}_{1,s} - u_{1,s}$ and $\hat{u}_{1,s} - \hat{u}_{2,s}$ by dividing their standard deviation estimators. If we assume that $U$-statistics have the same variance under the null hypothesis (homogeneity assumption), we can build $W_{(s_0,p)}$ and $N_{(s_0,p)}$ without the normalization to avoid introducing unnecessary estimation error. Therefore, $W_s$ and $N_s$ become

$$W_s := \hat{u}_{1,s} - u_{0,s} \quad \text{and} \quad N_s := \hat{u}_{1,s} - \hat{u}_{2,s}.$$ 

For the same reason, we set $W^b_s = \hat{u}^b_{1,s}$ and $N^b_s = \hat{u}^b_{1,s} - \hat{u}^b_{2,s}$ when performing bootstrap procedure of Sections 2.1.3 and 2.2. As the proof is similar for the test statistics without normalization, in Section 3 we only analyze the theoretical properties of the test statistics with normalization.

3. Theoretical properties. In this section, we discuss the theoretical properties of the proposed testing methods including the $(s_0,p)$-norm based test and data-adaptive combined test. We first introduce several assumptions in Section 3.1. We then analyze the asymptotic size and power of the $(s_0,p)$-norm based test in Section 3.2. At last, we analyze the data-adaptive combined test in Section 3.3.

3.1. Assumptions. Before presenting the theoretical properties, we introduce the assumptions that are needed in this paper. We also explain the intuitions of these assumptions. Throughout this paper, for the two-sample problem, we assume $n_1 \asymp n_2 \asymp n := \max(n_1,n_2)$, which means that $n_1, n_2$, and $n$ are of the same order. We then introduce some other assumptions. Assumption (A) characterizes the scaling of $s_0, q$, and $n$. Assumptions (E), (M1) and (M2) specify the requirements of the kernel functions. In detail, we introduce Assumption (A) as follows.

- (A) For the one-sample problem in (1.7), we assume that there is some $0 < \delta < 1/7$ such that $s_0^2 \log(q) = O(n_1^\delta)$ holds. For the two-sample problem in (1.8), we similarly assume that there is some $0 < \delta < 1/7$ such that $s_0^2 \log q = O(n^\delta)$ holds.

Assumptions (A) also allows $q$ and $s_0$ to go to the infinity, as long as $s_0^2 \log(qn) = o(n^\delta)$ holds with some $0 < \delta < 1/7$.

We then introduce the assumptions on the kernel functions of the $U$-statistics. For $x, x_1, \ldots, x_m \in \mathbb{R}^d$, define

$$\Psi(x_1, \ldots, x_m) := (\Psi_1(x_1, \ldots, x_m), \ldots, \Psi_q(x_1, \ldots, x_m))^\top$$

$$h(x) := (h_1(x), \ldots, h_q(x))^\top,$$
where \( \Psi_s \) and \( h_s \) are
\[
\Psi_s(x_{k_1}, \ldots, x_{k_m}) = \Phi_s(x_{k_1}, \ldots, x_{k_m}) - u_{1,s} \\
h_s(x_k) = E[\Psi_s(x_{k_1}, \ldots, x_{k_m})|x_k].
\]

Also, set \( \mathcal{V}_{s_0} := \{ v \in S^{q-1} : \|v\|_0 \leq s_0 \} \). With these introduced notations, by setting \( 0 < K, b < \infty \) as some positive constants, we are now ready to state Assumptions (E), (M1), and (M2).

- **(E)** For different indexes \( 0 < i_1, \ldots, i_m < n_1 \) and \( 0 < j_1, \ldots, j_m < n_2 \), we require
  \[
  \max_{1 \leq s \leq q} E[\exp(|\Psi_s(x_{i_1}, \ldots, x_{i_m})|/K)] \leq 2, \\
  \max_{1 \leq s \leq q} E[\exp(|\Psi_s(y_{j_1}, \ldots, y_{j_m})|/K)] \leq 2.
  \]

- **(M1)** \( E[\|v^T h(X)\|^2] \geq b \) and \( E[\|v^T h(Y)\|^2] \geq b \) hold for any \( v \in \mathcal{V}_{s_0} \).

- **(M2)** For \( \ell = 1, 2 \), we require
  \[
  \max_{1 \leq s \leq q} E[|h_s(x)|^{2+\ell}] \leq K^\ell, \\
  \max_{1 \leq s \leq q} E[|h_s(y)|^{2+\ell}] \leq K^\ell.
  \]

Assumption (E) requires that \( \Psi_s(x_{i_1}, \ldots, x_{i_m}) \) and \( \Psi_s(y_{j_1}, \ldots, y_{j_m}) \) follow the sub-exponential distribution. Especially, bounded \( \Psi_s \) including useful rank-based \( U \)-statistics such as Kendall’s tau and Spearman’s rho satisfy this condition. Assumption (M1) excludes degenerate \( U \)-statistics. Moreover, it also requires that the inner product of \( h(X) \) (or \( h(Y) \)) and any \( v \in \mathcal{V}_{s_0} \) is not degenerated. The distribution assumptions (E), (M1), and (M2) are useful for applying high-dimensional central limiting theorem (CLT) in Lemma A.1. These assumptions are also justified by [24].

### 3.2. Theoretical properties of \((s_0, p)\)-norm based test statistics

After introducing the assumptions in Section 3.1, we now state the theoretical properties of the \((s_0, p)\)-norm based test. Firstly, we consider the asymptotic size. The following theorem justifies the multiplier bootstrap for \( W_{(s_0, p)} \) and \( N_{(s_0, p)} \), which is crucial for the size control.

**Theorem 3.1.** Suppose all assumptions in Section 3.1 hold. Under \( \mathcal{H}_0 \) of (1.7), we have
\[
\sup_{z \in (0, \infty)} \left| P(W_{(s_0, p)} \leq z) - P(W^b_{(s_0, p)} \leq z | \mathcal{X}) \right| = o_p(1), \text{ as } n_1 \to \infty.
\]

Similarly, under \( \mathcal{H}_0 \) of (1.8) we have
\[
\sup_{z \in (0, \infty)} \left| P(N_{(s_0, p)} \leq z) - P(N^b_{(s_0, p)} \leq z | \mathcal{X}, \mathcal{Y}) \right| = o_p(1), \text{ as } n \to \infty.
\]
Proof. The proof of (3.2) is similar to that of (3.3). For simplicity, we only present the proof of (3.3), which consists of three steps. We first analyze the approximate distribution of $N$. We then obtain the distribution of the bootstrap sample $N^b$ given $X$ and $Y$. At last, we analyze the approximation error between $N$ and $N^b|X,Y$ to yield (3.3). We only sketch the proof here. More detailed proof is presented in Appendix B.2 of supplementary materials.

Step (i) (Sketch). In this step, we aim to obtain the approximate distribution of $N$ under the null hypothesis. Under the null hypothesis we have $u_{1,s} = u_{2,s}$. Therefore, we rewrite $N_s$ as

$$N_s = (\bar{u}_{1,s} - \bar{u}_{2,s})/\sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2},$$

where $\bar{u}_{\gamma,s} := \tilde{u}_{\gamma,s} - u_{\gamma,s}$ is the centered version of $\tilde{u}_{\gamma,s}$. As $\bar{u}_{\gamma,s}$ is also a $U$-statistic, by the Hoeffding’s decomposition we can approximate $\bar{u}_{\gamma,s}$ by a sum of independent random variables. In detail, we use $(m/n_1)\sum_{k=1}^{n_1} h_s(X_k)$ and $(m/n_2)\sum_{k=1}^{n_2} h_s(Y_k)$ to approximate $\bar{u}_{1,s}$ and $\bar{u}_{2,s}$. By setting

$$\sigma_{1,st} = \mathbb{E}(h_s(X)h_t(X)) \quad \text{and} \quad \sigma_{2,st} = \mathbb{E}(h_s(Y)h_t(Y))$$

for $1 \leq s, t \leq q$, as $n \to \infty$ we have $\hat{v}_{\gamma,s} \to m^2\sigma_{\gamma,ss}$, which motivates us to define

$$H^N_s = \left(\frac{1}{n_1}\sum_{k=1}^{n_1} h_s(X_k) - \frac{1}{n_2}\sum_{k=1}^{n_2} h_s(Y_k)\right)/\sqrt{\sigma_{1,ss}/n_1 + \sigma_{2,ss}/n_2}.$$ 

By setting $H^N = (H^N_1, \ldots, H^N_q)^\top$, we use $H^N$ as an approximation of $N$. However, we don’t know the exact distribution of $H^N$. As $H^N$ is a sum of independent random vectors with zero mean, by the central limit theorem we can use a normal random vector to further approximate $H^N$.

Let $G^N$ be a Gaussian random vector with the same mean vector and covariance matrix as $H^N$. By setting $\Sigma_1 := (\sigma_{1,st}), \Sigma_2 := (\sigma_{2,st}) \in \mathbb{R}^{q \times q}$, we have

$$G^N \sim N(0, R_{12}) \quad \text{with} \quad R_{12} := D_{12}^{-1/2}\Sigma_1 D_{12}^{-1/2},$$

where we set

$$\Sigma_{12} = \Sigma_1/n_1 + \Sigma_2/n_2 \quad \text{and} \quad D_{12} = \text{Diag}(\Sigma_{12}).$$

We then use the distribution of $G^N$ to approximate that of $N$. 
Step (ii) (Sketch). In this step, we aim to obtain the distribution of \( N^b|\mathcal{X},\mathcal{Y} \). We rewrite \( \hat{u}^b_1,s \) and \( \hat{u}^b_2,s \) in (2.1.3) as

\[
\hat{u}^b_1,s = \frac{m}{n_1} \sum_{k=1}^{n_1} (Q_{1k,s} - \bar{u}_{1,s}) \varepsilon_{b,1,k}, \quad \hat{u}^b_2,s = \frac{m}{n_2} \sum_{k=1}^{n_2} (Q_{2k,s} - \bar{u}_{2,s}) \varepsilon_{b,2,k},
\]

where \( Q_{1k,s} \) and \( Q_{2k,s} \) are defined in (2.2). Considering that \( \varepsilon_{b,1}, \ldots, \varepsilon_{b,n_1} \) are independent standard normal random variables, by (3.8) we have \( \hat{u}^b_{\gamma} := \left( \hat{u}^b_{\gamma,1}, \ldots, \hat{u}^b_{\gamma,q}\right) \mid \mathcal{X}, \mathcal{Y} \sim N(0, m^2 \hat{\Sigma}_{\gamma}/n_{\gamma}) \) with \( \hat{\Sigma}_{\gamma} := (\hat{\sigma}_{\gamma,ss}) \in \mathbb{R}^{q \times q} \) and

\[
\hat{\sigma}_{\gamma,ss} = \frac{1}{n_{\gamma}} \sum_{k=1}^{n_1} (Q_{\gamma k,s} - \hat{u}_{\gamma,s})(Q_{\gamma k,t} - \hat{u}_{\gamma,t}),
\]

for \( \gamma = 1, 2 \). Apparently, by the definition of \( \hat{v}^b_{\gamma,s} \) in (2.1) we have \( \hat{v}^b_{\gamma,s} = m^2 \hat{\sigma}_{\gamma,ss} \). By setting \( \hat{R}_{12} = \hat{D}_{12}^{-1/2} \Sigma_{12} \hat{D}_{12}^{-1/2} \), given \( \mathcal{X} \) and \( \mathcal{Y} \) we have

\[
N^b = m^{-1} \hat{D}_{12}^{-1/2} \left( \hat{u}^b_1 - \hat{u}^b_2 \right) \sim N(0, \hat{R}_{12}),
\]

where we set \( \hat{R}_{12} = \hat{D}_{12}^{-1/2} \Sigma_{12} \hat{D}_{12}^{-1/2} \).

Step (iii) (Sketch). In this step, we aim to obtain the approximation error between \( N^b \) and \( N^b|\mathcal{X},\mathcal{Y} \). For this, we analyze the estimation error between \( \hat{R}_{12} \) and \( R_{12} \). We then combine results from Steps (i) and (ii) to finish the proof of (3.3). The detailed proof is in Appendix B.2 of supplementary materials.

Remark 3.2. Assumption (A) requires that \( s_{0}^{\delta} \log(q) = O(n^{d}) \) holds with \( \delta = 2 \) and \( 0 < \delta < 1/7 \). However, \( \delta = 2 \) is not optimal for each individual \( p \). By the proof of Theorem 3.1, \( \delta \) depends on the facet number of a polytope to approximate \( B_{(s_{0},p)}(x) = \{ v \in \mathbb{R}^{q} : \| v \|_{(s_{0},p)} \leq x \} \). If \( p = 1 \), \( B_{(s_{0},p)}(x) \) itself is a polytope, which makes \( \delta = 1 \) is enough for obtaining (3.2) and (3.3). Similarly, If \( p = \infty \), \( \delta = 0 \) is sufficient. To make (3.2) and (3.3) hold for any \( p \in [1, \infty] \), by Lemma A.3 in Appendix A, we set \( \delta = 2 \) in Theorem 3.1.

As an implication of Theorems 3.1, the following corollary shows that under mild moment conditions on the kernel functions of \( U \)-statistics, by using the multiplier bootstrap introduced in Section 2.1.3, the size of \( (s_{0},p) \)-norm based test is asymptotically \( \alpha \), as desired.
COROLLARY 3.1. Suppose all assumptions in Section 3.1 hold. For the one-sample problem in (1.7), under $H_0$ of (1.7) we have

$$
P_{H_0}(T_{\alpha,(s_0,p)}^W = 1) \rightarrow \alpha \quad \text{and} \quad \tilde{P}_{(s_0,p)}^W - P_{(s_0,p)}^W \rightarrow 0,$$

as $n_1, B \to \infty$. Similarly, for the two-sample problem in (1.8), under $H_0$ of (1.8) we have

$$
P_{H_0}(T_{\alpha,(s_0,p)}^N = 1) \rightarrow \alpha \quad \text{and} \quad \tilde{P}_{(s_0,p)}^N - P_{(s_0,p)}^N \rightarrow 0,$$

as $n, B \to \infty$.

The detailed proof of Corollary 3.1 is in Appendix B.3 of supplementary materials. After analyzing the asymptotic size of the $(s_0,p)$-norm based test, we now turn to the analysis of its power. For this, we need the following notations: $D_1 = (D_{1,1}, \ldots, D_{1,q})^\top$ and $D_2 = (D_{2,1}, \ldots, D_{2,q})^\top$ with

$$
D_{1,s} = |u_{1,s} - u_{0,s}|/\sqrt{m^2\sigma_{1,ss}/n_1},
$$

$$
D_{2,s} = |u_{1,s} - u_{2,s}|/\sqrt{m^2\sigma_{1,ss}/n_1 + m^2\sigma_{2,ss}/n_2},
$$

where $\sigma_{\gamma,ss}$ is defined in (3.4). We need new Assumption (A)' to describe the scaling between $s_0, q$, and $n$ for test statistics $W_{(s_0,p)}$ and $N_{(s_0,p)}$ to reject with overwhelming probability under the alternative.

- (A)' For the one-sample problem in (1.7), we assume $\log q = o(n_1^{1/3})$ and $n_1 = O(q^{\delta_1})$ with some $\delta_1 > 0$, as $n_1, q \to \infty$. For the two-sample problem in (1.8), we assume $\log q = o(n^{1/3})$ and $n = O(q^{\delta_1})$ with some $\delta_1 > 0$, as $n, q \to \infty$. Moreover, we also assume that there is a constant $\delta_2 > 0$ such that $s_0 = O(\log^{\delta_2}(q))$ holds for both problems.

After the introduction of Assumption (A)', we then state the theorem that characterizes the power of $W_{(s_0,p)}$ and $N_{(s_0,p)}$.

THEOREM 3.3. Suppose Assumptions (A)', (E), (M1), and (M2) hold. For the one-sample problem in (1.7), we assume $\varepsilon_{n_1} = o(1)$ with $\varepsilon_{n_1}\sqrt{\log q} \to \infty$ as $n_1, q \to \infty$. If $H_1$ of (1.7) holds with

$$
\|D_1\|_{(s_0,p)} \geq s_0(1 + \varepsilon_{n_1})(\sqrt{2\log q} + \sqrt{2\log(1/\alpha)}),
$$

we have $P_{H_1}(T_{(s_0,p)}^W = 1) \to 1$ as $n_1, q, B \to \infty$. Similarly, for the two-sample problem in (1.8) we assume $\varepsilon_n = o(1)$, and $\varepsilon_n\sqrt{\log q} \to \infty$ as $n, q \to \infty$. If $H_1$ of (1.8) holds with

$$
\|D_2\|_{(s_0,p)} \geq s_0(1 + \varepsilon_n)(\sqrt{2\log q} + \sqrt{2\log(1/\alpha)}),
$$

we have $P_{H_1}(T_{(s_0,p)}^N = 1) \to 1$ as $n, q, B \to \infty$. 
The detailed proof of Theorem 3.3 is presented in Appendix B.4 of supplementary materials. The scaling of \( q \) and \( n \) in Theorem 3.3 is weaker than Assumption (A), allowing larger \( q \) for proposed tests to correctly reject the null hypothesis. Moreover, by the proof of Theorem 3.3, for \( m = 1 \), we can further relax the conditions \( \log q = o(n^{1/3}) \) and \( \log q = o(n^{1/3}) \) by \( \log q = o(n^{1/2}) \) and \( \log q = o(n^{1/2}) \) in Assumption (A)'.

3.3. Theoretical properties of \( W_{ad} \) and \( N_{ad} \). In Section 2.2, we introduce the data-adaptive test by combining the \((s_0, p)\)-norm based tests with \( p \in \mathcal{P} \), where \( \mathcal{P} \subset \{1, 2, \ldots, \infty\} \) is a finite fixed set specified by users. Intuitively, by combining tests with various norms, the data-adaptive test enjoys high power across various alternative hypothesis scenarios. In (2.9) and (2.10), we introduce the data-adaptive tests as

\[
W_{ad} = \min_{p \in \mathcal{P}} \tilde{P}_W^{(s_0, p)} \quad \text{and} \quad N_{ad} = \min_{p \in \mathcal{P}} \tilde{P}_N^{(s_0, p)},
\]

where \( \tilde{P}_W^{(s_0, p)} \) and \( \tilde{P}_N^{(s_0, p)} \) are defined in (2.8). By setting \( F_{W,(s_0,p)}(z) := \mathbb{P}(W_{(s_0,p)} \leq z) \) and \( F_{N,(s_0,p)}(z) := \mathbb{P}(N_{(s_0,p)} \leq z) \), we have that the oracle \( P \)-values of \( W_{(s_0,p)} \) and \( N_{(s_0,p)} \) are

\[
P_W^{(s_0,p)} := 1 - F_{W,(s_0,p)}(W_{(s_0,p)}) \quad \text{and} \quad P_N^{(s_0,p)} := 1 - F_{N,(s_0,p)}(N_{(s_0,p)}).
\]

By the definitions of \( \tilde{P}_W^{(s_0, p)} \) and \( \tilde{P}_N^{(s_0, p)} \) in (2.8), \( \tilde{P}_W^{(s_0, p)} \) and \( \tilde{P}_N^{(s_0, p)} \) estimate \( P_W^{(s_0,p)} \) and \( P_N^{(s_0,p)} \). Therefore, by (3.16) \( W_{ad} \) and \( N_{ad} \) estimate

\[
\tilde{W}_{ad} = \min_{p \in \mathcal{P}} P_W^{(s_0, p)} \quad \text{and} \quad \tilde{N}_{ad} = \min_{p \in \mathcal{P}} P_N^{(s_0, p)}.
\]

By setting \( \tilde{F}_{W,ad}(z) := \mathbb{P}(\tilde{W}_{ad} \leq z) \) and \( \tilde{F}_{N,ad}(z) := \mathbb{P}(\tilde{N}_{ad} \leq z) \), considering that the small values of \( W_{ad} \) and \( N_{ad} \) yield the rejection of the null hypotheses, we have that the oracle \( P \)-values of \( W_{ad} \) and \( N_{ad} \) are \( \tilde{F}_{W,ad}(\tilde{W}_{ad}) \) and \( \tilde{F}_{N,ad}(\tilde{N}_{ad}) \).

After introducing these notations, we aim to justify the bootstrap procedure in Section 2.2 by showing that \( \tilde{P}_W^{ad} \) and \( \tilde{P}_N^{ad} \) (defined in (2.11) and (2.13)) are consistent estimators of the oracle \( P \)-values \( \tilde{F}_{W,ad}(\tilde{W}_{ad}) \) and \( \tilde{F}_{N,ad}(\tilde{N}_{ad}) \). For this, we introduce Assumption (A)' to specify the scaling between \( s_0 \), \( q \) and \( n \) for the data-adaptive combined test.

To state Assumption (A)" we need some additional notations. For the two-sample problem, we introduce \( G^N \sim N(0, R_{12}) \in \mathbb{R}^d \) in (3.6) to approximate \( N \). We set \( f_{G^N,(s_0,p)}(x) \) and \( c_{G^N,(s_0,p)}(\alpha) \) as the probability density
function and the \(\alpha\)-quantile of \(\|G^N\|^{(s_0,p)}\). We then define \(h_{q,N}(\epsilon)\) as
\[
h_{q,N}(\epsilon) = \max_{p \in P} \max_{x \in I^{N,(s_0,p)}(\epsilon)} f_{G^N,(s_0,p)}^{-1}(x),
\]
where \(I^{N,(s_0,p)}(\epsilon) = [c_{G^N,(s_0,p)}(\epsilon), c_{G^N,(s_0,p)}(1-\epsilon)]\). For the one-sample problem, we define \(h_{q,W}(\epsilon)\) similarly for \(G^W \sim N(0, R_1) \in \mathbb{R}^q\), where
\[
R_1 = (r_{1,st}) \in \mathbb{R}^{q \times q} \quad \text{with} \quad r_{1,st} = \text{Corr}(h_s(X), h_t(X)).
\]
By definition, \(R_1\) and \(R_{12}\) are the asymptotic correlation matrices of \(W\) and \(N\), where \(W\) and \(N\) are defined in (2.4). With these additional notations, we then state Assumption (A)'' as follows.

- (A)'' Under (1.7), as \(n_1 \to \infty\), we assume that \(h_{q,W}(\epsilon)\) holds for any \(0 < \epsilon < 1\). Under (1.8), as \(n \to \infty\), we assume that \(h_{q,N}(\epsilon)\) holds for any \(0 < \epsilon < 1\).

Compared to Assumption (A), the required scaling in Assumption (A)'' is more stringent. This is because when analyzing the combined test, we need not only the convergence of distribution functions of the test statistics but also their uniform convergence of the quantile functions on \([\epsilon, 1-\epsilon]\).

**Remark 3.4.** Let \(1 \leq s_0, \#(P) < \infty\). If there are \(0 < C_0 < \infty\) and \(0 < \eta < 1\) such that \(C_0^{-1} < \min_i(R_{12}) \leq \max_i(R_{12}) < C_0\) and \(\max_{i \neq j} |r_{ij}| < \eta\), we have \(h_{q,N}(\epsilon) = O(1)\) for any \(\epsilon \in (0,1)\), as \(q \to \infty\). Similarly, if \(C_0^{-1} < \min_i(R_1) \leq \max_i(R_1) < C_0\) and \(\max_{i \neq j} |r_{ij}| < \eta\), we also have \(h_{q,W}(\epsilon) = O(1)\) for any \(\epsilon \in (0,1)\), as \(q \to \infty\). The detailed proof is in Appendix B.6 of supplementary materials.

The detailed proof of Remark 3.4 is in Appendix B.6 of supplementary materials, in which we obtain a joint asymptotic distribution for the order statistics of nonindependent Gaussian random variables. This result is non-trivial and of independent technical interest. After introducing additional assumptions, we then justify the data-adaptive combined test by the following theorem.

**Theorem 3.5.** Suppose Assumptions (A)'', (E), (M1) and (M2) hold. For the one-sample problem, under \(H_0\) of (1.7) we have
\[
P_{H_0}(T_{ad}^W = 1) \to \alpha \quad \text{and} \quad \tilde{F}_{W,ad}(\tilde{W}_{ad}) - \tilde{P}_{ad}^W \to 0 \quad \text{as} \quad n_1, B \to \infty.
\]
Similarly, for the two-sample problem, under \(H_0\) of (1.8) we have
\[
P_{H_0}(T_{ad}^N = 1) \to \alpha \quad \text{and} \quad \tilde{F}_{N,ad}(\tilde{N}_{ad}) - \tilde{P}_{ad}^N \to 0 \quad \text{as} \quad n, B \to \infty.
\]
The detailed proof of Theorem 3.5 is in Appendix B.5 of supplementary materials.

**Remark 3.6.** To prove Theorem 3.5, we first show that for any fixed $0 < \epsilon < 1$, not only the distribution function of $N_{ad}$ but also its quantile function on $[\epsilon, 1-\epsilon]$ converge to those of $\tilde{N}_{ad}$. By choosing $\epsilon$ sufficiently small, we then prove that the probability of $\tilde{N}_{ad} \in (0, \epsilon)$ is negligible to finish the proof. If $\#(P) \to \infty$, we cannot guarantee $\tilde{N}_{ad} \in (0, \epsilon)$ is negligible any more. Moreover, it is also very hard to prove the convergence of quantile functions on $(\epsilon, 1-\epsilon)$ for $N_{ad}$ with $\epsilon \to 0$. Hence, when constructing the combined test, we require $0 < \#(P) < \infty$. By simulation, we recommend using $P = \{1, 2, 3, 4, 5, \infty\}$. The simulation also shows that there is no significant power advantage to add more elements to $P$ (see Appendix F.3). Therefore, the assumption of finite $\#(P)$ is enough for the practical usage.

We now turn to the analysis of the power of the combined test. For this, we have the following result.

**Theorem 3.7.** Suppose Assumptions (A)', (E), (M1), and (M2)) hold. For the one-sample problem in (1.7), we assume $\log q = o(n_1^{1/2})$, $\varepsilon_{n_1} = o(1)$, and $\varepsilon_{n_1} \sqrt{\log q} \to \infty$ as $n_1, q \to \infty$. If $H_1$ of (1.7) holds with

$$
\|D_1\|_{(s_0, p)} \geq s_0(1 + \varepsilon_{n_1})\left(\sqrt{2 \log q} + \sqrt{2 \log(\#(P)/\alpha)}\right),
$$

we have $P_{H_1}(T_{ad}^W = 1) = 1$ as $n_1, q, B \to \infty$. Similarly, for the two-sample problem in (1.8) we assume $\log q = o(n_1^{1/2})$, $\varepsilon_n = o(1)$, and $\varepsilon_n \sqrt{\log q} \to \infty$ as $n, q \to \infty$. If $H_1$ of (1.8) holds with

$$
\|D_2\|_{(s_0, p)} \geq s_0(1 + \varepsilon_n)\left(\sqrt{2 \log q} + \sqrt{2 \log(\#(P)/\alpha)}\right),
$$

we have $P_{H_1}(T_{ad}^N = 1) \to 1$ as $n, q, B \to \infty$.

The detailed proof of Theorem 3.7 is presented in Appendix B.7 of supplementary materials.

**Remark 3.8.** On one hand, by Theorems 3.3 and 3.7, we require $\|u_1 - u_0\|_{(s_0, p)} \geq s_0 \sqrt{\log(q)/n_1}$ or $\|u_1 - u_2\|_{(s_0, p)} \geq s_0 \sqrt{\log(q)/n}$ for our proposed methods to reject the null hypothesis with overwhelming probability. On the other hand, by Theorem 3 in [14, 15], Theorem 4.3 in [35], and Theorem 3.5 in [74], for both vector-based and matrix-based high dimensional tests, any $\alpha$-level test is unable to reject the null hypothesis correctly uniformly over $\|\mu_1 - \mu_0\|_{\infty} \geq c_0 \sqrt{\log(d)/n}$ or $\|\mu_1 - \mu_0\|_{\infty} \geq c_0 \sqrt{\log(d)/n}$ with $c_0$ sufficiently small. Therefore, we have that our proposed methods with finite $s_0$ are rate-optimal for these sparse alternatives.
4. Simulation results. The goal of this section is to investigate the numerical performance of the proposed tests. For this, we compare our methods with several existing methods from the literature. In this section, we only consider the high dimensional mean test under different settings. We put additional simulation results for testing high-dimensional covariance/correlation coefficients in Appendix F to illustrate the proposed methods’ generality. Apart from simulated datasets, Appendix F also includes the experimental results on real world fMRI datasets.

In the context of high dimensional mean test, we compare the proposed tests with four existing methods: Hotelling’s $T^2$ test, the $L^2$-type tests given in [5] and [67], and the $L^\infty$-type test give in [15]. We refer these four tests as $T^2$, BY, SD, and CLX. For simplicity, we only consider the two-sample problem. We generate synthetic data from a wide range of covariance structure including both sparse and non-sparse settings. We also consider a wide range of alternative scenarios including both sparse and dense settings to investigate the power of the proposed methods.

Under the null hypothesis, we sample $n_1 + n_2$ data points from the following models:

- **Model 1.** (Gaussian distribution with block diagonal $\Sigma$) We set $\Sigma^* = (\sigma^*_{ij}) \in \mathbb{R}^{d \times d}$ with $\sigma^*_{ii} \sim U(1, 2)$, $\sigma^*_{ij} = 0.5$ for $5(k - 1) + 1 \leq i \neq j \leq 5k$, where $k = 1, \ldots, \lfloor d/5 \rfloor$, and $\sigma^*_{ij} = 0$ otherwise. In this model, under the null hypothesis we generate $n_1 + n_2$ random vectors from $N(0, \Sigma^*)$.

- **Model 2.** (Gaussian distribution with banded $\Sigma$) We set $\Sigma' = (\sigma'_{ij}) \in \mathbb{R}^{d \times d}$ with $\sigma'_{ij} = 0.4^{|i-j|}$ for $1 \leq i, j \leq d$. In this model, under the null hypothesis we generate $n_1 + n_2$ random vectors from $N(0, \Sigma')$.

- **Model 3.** (Gaussian distribution with non-sparse $\Sigma$) We set $F = (f_{ij}) \in \mathbb{R}^{d \times d}$ with $f_{ii} = 1$, $f_{i+1,i} = f_{i+1,i+1} = 0.5$, and $f_{ij} = 0$ otherwise. We also set that $U \sim U(\Lambda_{d,k})$ follows the uniform distribution on the Stiefel manifold $\Lambda_{d,k}$ (i.e., $\Lambda_{d,k} = \{H \in \mathbb{R}^{d \times k} : H^\top H = I_k\}$). After introducing $F$ and $U$, we then set the correlation matrix as $R = (D^f)^{-1/2}(F + UU^\top)(D^f)^{-1/2}$ with $D^f = \text{Diag}(F + UU^\top)$. By setting $D = (d_{ij}) \in \mathbb{R}^{d \times d}$ as a diagonal matrix with $d_{ii} \sim U(1, 2)$, we generate $n_1 + n_2$ random vectors from $N(0, \Sigma)$ with $\Sigma = D^{1/2}RD^{1/2}$.

- **Model 4.** (Multivariate $t$ distribution) We generate $n_1 + n_2$ random vectors from the multivariate $t$ distribution $t(\nu, \mu, \Sigma)$ according to $\mu + Z/\sqrt{W/\nu}$, where we have $W \sim \chi^2(\nu)$ and $Z \sim N(0, \Sigma)$ with $W$ and $Z$ independent of each other. In the simulation, we set $\mu = 0$, $\nu = 5$, and $\Sigma = \Sigma^*$.
We use the above models to show that the proposed methods are valid given a fixed size $\alpha$ under various covariance structures and distributions. To present the empirical power of the proposed methods, we introduce a random vector $V \in \mathbb{R}^d$ with exactly $s$ nonzero entries, which are selected randomly from $d$ coordinates. Each nonzero entry follows an independent uniform distribution $U(u_1, u_2)$. Under the alternative hypothesis, we set $\mu_1 = 0$ and $\mu_2 = V$. By choosing different $s$, $u_1$, and $u_2$, we compare the power of the proposed methods with that of the existing methods under both the sparse and non-sparse settings.

| $d$ | $s_0$ | $p = 1$ | $p = 2$ | $p = 3$ | $p = 4$ | $p = 5$ | $p = \infty$ | $T^2$ | BY | SD | CLX |

| 800 | 0.40 | 0.55   | 0.75   | 1.35   | 1.85   | 8.65   | 3.65        | -    | 5.65| 4.65| 7.45|

In Table 1, we present the empirical sizes of introduced methods for Model 1. We set $n_1 = n_2 = n = 100$ and $q = d = 75, 200, 400, 800$. The nominal significance level is 0.05. We compare our methods with four other tests: $T^2$, BY, SD, and CLX. Moreover, $T^2$, BY, and SD are $L_2$-type and CLX is $L_\infty$-type. The $T^2$ test requires $d < n$, so that we don’t perform $T^2$ test as $d > n$. In the current setting, the four existing methods can control the size correctly, except that CLX test suffers a size distortion as $d$ is significantly larger ($d = 800$) than $n$. For the $(s_0, p)$-norm based tests, when $s_0$ is significantly smaller ($s_0 = 5, 10$) than $d$, they can control the size correctly, except that the $(s_0, \infty)$-norm based test suffers a size distortion as $d$ is significantly large ($d = 800$). As $s_0$ increases, the empirical size of
Table 2: Empirical power of Model 1 with $\alpha = 0.05$, $B = 300$, and $n_1 = n_2 = 100$ based on 2000 replications.

| $d$ | $s_0$ | $p = 1$ | $p = 2$ | $p = 3$ | $p = 4$ | $p = 5$ | $p = \infty$ | $T_{ad}^N$ | $T^2$ | BY | SD | CLX |

$s_0$, $p$-norm based tests decreases dramatically especially for small $p$, making the $(s_0, p)$-norm based tests with small $p$ overly conservative. Although the $(s_0, p)$-norm based tests perform differently with different $s_0$ and $p$, the data-adaptive combined test $T_{ad}^N$ can control the size correctly under various settings of $d$ and $n$.

In Table 2, we compare these methods under different alternative scenarios. In the sparse alternative setting, we set $\mu_2 = V$ with $s = 5$ nonzero entries. Each entry follows independent uniform distribution $U(0, 4\sqrt{\log(d)/n})$. In this setting, the $L_\infty$-type test achieves a higher empirical power than the $L_2$-type tests. In the dense alternative setting, we set $\mu_2 = V$ with $s = 100$ nonzero entries of the magnitude $U(0, 3n^{-1/2})$. In this setting, the $L_2$-type tests are more powerful. This similar pattern also appears in the $(s_0, p)$-norm based tests. As $p$ increases, the $(s_0, p)$-norm based test is more sensitive to the sparse alternative. The influence of $s_0$ is more complicated. However, by choosing $s_0$ close to $s$, the tests always enjoy good performance. For the
data-adaptive combined test $T_{ad}^N$, we choose a balanced $\mathcal{P}$ including both small and large values of $p$. Hence, in various settings of the alternative scenarios, $d$, and $n$, it always has a high power. Although $T_{ad}^N$ with balanced $\mathcal{P}$ may not be the most powerful option for some alternatives, $T_{ad}^N$ is adaptive to the alternative setting and powerful enough in various kinds of alternative scenarios. Theoretically, there is no uniformly most powerful test in all the alternative scenarios [26]. If the alternative pattern is unknown, the data-adaptive test with balanced $\mathcal{P}$ (including small and large $p$) is a good choice. If the alternative pattern is known, by choosing $\mathcal{P}$ accordingly we can still construct a powerful test. For the choice of $s_0$, similarly to the $(s_0, p)$-norm based tests, $T_{ad}^N$ with $s_0$ close to $s$ is always powerful.

We put the numerical results of Models 2-4 in Appendix F of supplementary materials. Their experimental results are similar to Model 1 and indicate that the proposed methods work well in various settings.

5. Summary and discussion. This paper considers the problem of testing high dimensional $U$-statistic based vectors. We construct a family of tests based on the $(s_0, p)$-norm. By the introduction of $s_0$, when $q$ is large, we can increase the power compared to the tradition $L_p$-norm based test (especially for small $p$). Moreover, by choosing $p$ properly, we can further enhance the power under different alternatives. We also introduce a data-adaptive combined test, which is simultaneously powerful under a wide variety of alternatives. Moreover, We also develop a trick for avoiding the high computational cost of the double-loop bootstrap for the data-adaptive combined test with theoretical guarantee in high dimensions.

We then discuss the choice of $s_0$ and $\mathcal{P}$. Theoretically, for individual $(s_0, p)$-norm tests we generally require that $s_0^\delta \log q = o(n^\delta)$ holds with $\delta = 2$ and $0 < \delta < 1/7$ for all $p \in [1, \infty]$. We also point out that it is possible to reduce $\delta$ for some specified $p$. For combined tests, we require $0 < \#(\mathcal{P}) < \infty$ to prevent the test statistic from going to 0. By simulation, we also see that the proposed tests with $s_0$ close to $s$ (true unknown number of entries violating $H_0$) enjoy high power, which makes $s$ a good candidate for $s_0$.

In practice, we recommend choosing $s_0$ and $s$ as close as possible without violating theoretical conditions.

There are several possible future directions of this work. For instance, how to generalize the idea to the $k$-sample testing problems ($k > 2$) has been for a future investigation. This may require a nontrivial extension of the theoretical analysis. Moreover, our theory is based on the Gaussian approximation for the sum of high dimensional independent random vectors from [23], [73] and [72] further study Gaussian approximations for high di-
mensional time series, which allow to generalize our methods for dependent data. As a significant amount of additional work is still needed, we shall report the results elsewhere in the future.

SUPPLEMENT MATERIALS TO “A UNIFIED FRAMEWORK FOR TESTING HIGH DIMENSIONAL PARAMETERS: A DATA-ADAPTIVE APPROACH”

By Cheng Zhou‡, Xinsheng Zhang‡, Wenxin Zhou§ and Han Liu§

Department of Statistics, Fudan University‡ and Department of Operation Research and Financial Engineering, Princeton University§

ABSTRACT

The supplementary materials contain additional details of the paper “A Unified Framework for Testing High Dimensional Parameters: A Data-Adaptive Approach” authored by Cheng Zhou, Xinsheng Zhang, Wenxin Zhou, and Han Liu. After introducing some useful lemmas in Appendix A, we prove main results in Appendix B. In Appendices C and D, we prove lemmas required by the proofs in Appendix B. In Appendix E, we prove lemmas introduced in Appendix A. In Appendix F, we present additional numerical experimental results. Throughout supplementary materials, we use $C, C_1, C_2, \ldots$ to denote constants which do not depend on $n, d,$ and $q$. These constants can vary from place to place.

APPENDIX A: USEFUL LEMMAS

In Appendix A, we introduce some useful lemmas that will be used many times for proving main results. We put their proof in Appendix E. To present these lemmas, we need some additional notations. Let $Z_1, \ldots, Z_n$ be independent random vectors in $\mathbb{R}^d$ with $Z_k = (Z_{k1}, \ldots, Z_{kd})^\top$ and $\mathbb{E}[Z_k] = 0$ for $k = 1, \ldots, n$. Let $W_1, \ldots, W_n$ be independent Gaussian random vectors in $\mathbb{R}^d$ such that $W_k$ has the same mean vector and covariance matrix as $Z_k$. By setting $V_{s_0} := \{v \in S^{d-1} : \|v\|_0 \leq s_0\}$, we require the following conditions:

- $(M1)' \quad n^{-1} \sum_{k=1}^n \mathbb{E}[(v' Z_k)^2] \geq b > 0$ for any $v \in V_{s_0}$;
- $(M2)' \quad n^{-1} \sum_{k=1}^n \mathbb{E}[|Z_{kj}|^{2+\ell}] \leq K^\ell$ for $\ell = 1, 2$ and $j = 1, \ldots, d$.
- $(E)' \quad \mathbb{E}[^{\ell} \exp(|Z_{kj}|/K)] \leq 2$ for $j = 1, \ldots, d$ and $k = 1, \ldots, n$.

Lemma A.1. Assume $s_0^2 \log(dn) = O(n^\zeta)$ with $0 < \zeta < 1/7$. If $Z_1, \ldots, Z_n$ satisfy $(M1)', (M2)', (E)'$. By setting $S_n^Z = n_1^{-1/2} \sum_{k=1}^n Z_k$ and $S_n^W = n_1^{-1/2} \sum_{k=1}^n W_k$, for $1 \leq p \leq \infty$ and sufficiently large $n$, there is a constant $\zeta_0 > 0$ such that

$$\sup_{z \in (0, \infty)} \left| \mathbb{P}\left(\|S_n^Z\|_{(s_0,p)} \leq z\right) - \mathbb{P}\left(\|S_n^W\|_{(s_0,p)} \leq z\right) \right| \leq Cn^{-\zeta_0},$$

where $C$ depends on $b$ and $K$. 

(\ref{A.1})
Lemma A.2. (Corollary 1.2 in [2]) For any compact and symmetric convex set \( C \in \mathbb{R}^d \) with non-empty interior and \( \gamma > e/4\sqrt{2} \), there exist a polytope \( P \in \mathbb{R}^d \) and a constant \( \epsilon_\gamma > 0 \) such that for any \( 0 < \epsilon < \epsilon_\gamma \), we have
\[
P \subset C \subset (1 + \epsilon)P \quad \text{and} \quad V < \left( \frac{\gamma}{\sqrt{\epsilon}} \ln \frac{1}{\epsilon} \right)^d,
\]
where \( V \) is the vertex number of \( P \).

We call a set \( A^m \) \( m \)-generated if it is the intersection of \( m \) half-spaces. Therefore, \( A^m \) is a polytope with at least \( m \) facets. We then set \( V(A^m) \) as the set of \( m \) unit vectors that are outward normal to the facets of \( A^m \). For \( \epsilon > 0 \), we then define
\[
A^m,\epsilon := \cap_{v \in V(A^m)} \{ w \in \mathbb{R}^d : w^\top v \leq S_{A^m}(v) + \epsilon \},
\]
where \( S_{A^m}(v) := \sup \{ w^\top v : w \in A^m \} \).

Lemma A.3. Let \( E^{R,d} = \{ x \in \mathbb{R}^d : \| x \| \leq R \} \) and \( V_{z,d}^{z,d}(s_0,p) = \{ x \in \mathbb{R}^d : \| x \|_{(s_0,p)} \leq z \} \). For any \( \gamma > e/4\sqrt{2} \), there is a \( m \)-generated convex set \( A^m \in \mathbb{R}^d \) and a constant \( \epsilon_\gamma \) such that for any \( 0 < \epsilon < \epsilon_\gamma \), we have
\[
A^m \subset E^{R,d} \cap V_{z,d}^{z,d} \subset A^m,Re \quad \text{and} \quad m \leq d^{s_0} \left( \frac{\gamma}{\sqrt{\epsilon}} \ln \frac{1}{\epsilon} \right)^{s_0^2}.
\]

Lemma A.4. (Nazarov's inequality in [11]) Let \( W = (W_1, \ldots, W_d)^\top \in \mathbb{R}^d \) be centered Gaussian random vector with inf \( k=1,\ldots,d \) \( E[W_k^2] \geq b > 0 \). For any \( x \in \mathbb{R}^d \) and \( a > 0 \), we then have
\[
P(W \leq x + a) - P(W \leq x) \leq Ca\sqrt{\log d},
\]
where \( C \) only depends on \( b \).

Lemma A.5. \( W = (W_1, \ldots, W_d)^\top \) is a random vector with the marginal distribution \( N(0, \sigma^2) \). For any \( t > 0 \), we have
\[
E\left[ \max_{1 \leq i \leq d} |W_i| \right] \leq \frac{\log(2d)}{t} + \frac{t\sigma^2}{2}.
\]

To estimate the covariance matrix of \( U \)-statistic based vector, we introduce \( \sigma_{\gamma,\alpha} \) and \( \sigma_{\gamma,\beta} \) in (3.4) and (3.9). The following lemma then analyzes the estimation error of \( \sigma_{\gamma,\alpha} \). To analyze the correlation matrix, we also provide the approximation error of \( \sigma_{\gamma,\alpha} \), where
\[
r_{\gamma,\alpha} = \sigma_{\gamma,\alpha}/\sqrt{\sigma_{\gamma,\alpha}^2 \sigma_{\gamma,\alpha}^2} \quad \text{and} \quad \sigma_{\gamma,\alpha} = \sqrt{\sigma_{\gamma,\alpha}^2 \sigma_{\gamma,\alpha}^2}.
\]
Lemma A.6. Assumptions (E), (M1), and (M2) hold. For \( \log(qn) = o(n^{1/3}) \) and \( m > 1 \), when \( n \) is sufficiently large,

\[
\max_{1 \leq s, t \leq q} \max_{\gamma = 1, 2} \left( |\tilde{\sigma}_{\gamma, st} - \sigma_{\gamma, st}|, |\tilde{r}_{\gamma, st} - r_{\gamma, st}| \right) \leq C \frac{\log^{3/2}(qn)}{\sqrt{n}},
\]

(A.4)

holds with probability \( 1 - C_1 n^{-1} \). For \( \log(qn) = o(n^{1/2}) \) and \( m = 1 \), when \( n \) is sufficiently large,

\[
\max_{1 \leq s, t \leq q} \max_{\gamma = 1, 2} \left( |\tilde{\sigma}_{\gamma, st} - \sigma_{\gamma, st}|, |\tilde{r}_{\gamma, st} - r_{\gamma, st}| \right) \leq C \sqrt{\frac{\log(qn)}{n}} + C \frac{\log^2(qn)}{n},
\]

(A.5)

holds with probability \( 1 - C_1 n^{-1} \).

Appendix B: Proof of Main Results

In Appendix B, we present the detailed proofs of main results including Proposition 1, Theorems 3.1, 3.3, 3.5 3.7, Remarks 3.4, and Corollary 3.1.

B.1. Proof of Proposition 1.

Proof. We need to prove that for any \( 1 \leq p \leq \infty, a \in \mathbb{R} \) and \( x, y \in \mathbb{R}^d \), we have

(i) \( \|ax\|_{(s_0, p)} = |a|\|x\|_{(s_0, p)} \);

(ii) \( \|x + y\|_{(s_0, p)} \leq \|x\|_{(s_0, p)} + \|y\|_{(s_0, p)} \);

(iii) \( \|x\|_{(s_0, p)} = 0 \) implies \( x = \mathbf{0} \). By Definition 1.1, for \( x = (x_1, \ldots, x_d)^T \) we have

\[
\|x\|_{(s_0, p)} = \left( \sum_{j=d-s_0+1}^d (x(j))^p \right)^{1/p}.
\]

We use \( k_1 \) to denote the index of \( x^{(d-s_0+1)}, x^{(d-s_0+2)}, \ldots, x^{(d)} \). Therefore, we have \( \|x\|_{(s_0, p)} = \|x_{k_1}\|_p \), where \( x_{k_1} \in \mathbb{R}^{s_0} \). We then separately prove (i), (ii), and (iii). For (i), we have

\[
\|ax\|_{(s_0, p)} = \|ax_{k_1}\|_p = |a|\|x_{k_1}\|_p = |a|\|x\|_{(s_0, p)}.
\]

For (iii), from \( \|x\|_{(s_0, p)} = 0 \), we have \( x^{(d)} = 0 \), which implies \( x = \mathbf{0} \). Therefore, to prove Proposition 1, we only need to prove

\[
\|x + y\|_{(s_0, p)} \leq \|x\|_{(s_0, p)} + \|y\|_{(s_0, p)}.
\]

Similarly to the definition of \( k_1 \), we define \( k_2, k_{12} \) for \( y \) and \( x + y \). We then have

\[
\|y\|_{(s_0, p)} = \|y_{k_2}\|_p \quad \text{and} \quad \|x + y\|_{(s_0, p)} = \|(x + y)_{k_{12}}\|_p.
\]
For $1 \leq p \leq \infty$, $\| \cdot \|_p$ is a norm. Hence, we have

\[(B.2) \quad \| (x + y)_{k_2} \|_p = \| x_{k_2} + y_{k_2} \|_p \leq \| x_{k_2} \|_p + \| y_{k_2} \|_p.\]

By the definition of $k_1$ and $k_2$, we have

\[(B.3) \quad \| x_{k_1} \|_p \leq \| x \|_{(s_0, p)} \quad \text{and} \quad \| y_{k_2} \|_p \leq \| y \|_{(s_0, p)}.\]

Combining (B.1), (B.2), and (B.3), we have (iii), which finishes the proof. \[\square\]

**B.2. Proof of Theorem 3.1.**

**Proof.** In Theorem 3.1, we aim to prove (3.2) and (3.3). For simplicity, we only present the detailed proof of (3.3). According to the proof sketch in Section 3.2, the proof proceeds in three steps. In the first step, we obtain the approximate distribution of $N$. In the second step, given $X$ and $Y$, we obtain the bootstrap sample $N^b$'s distribution. In the last step, we analyze the approximation error between $N$ and $N^b|X,Y$ to yield (3.3).

**Step (i).** In this step, we aim to obtain the approximate distribution of $N$. As $\tilde{u}_{\gamma,s}$ is a $U$-statistic, by the Hoeffding decomposition we approximate $N$ by a sum of independent random vectors. Hence, we can further approximate the sum by its Gaussian counterpart. In detail, under the null hypothesis we have $u_{1,s} = u_{2,s}$. Therefore, we rewrite $N_s$ as

\[(B.4) \quad N_s = (\tilde{u}_{1,s} - \tilde{u}_{2,s})/\sqrt{\tilde{v}_{1,s}/n_1 + \tilde{v}_{2,s}/n_2},\]

where $\tilde{u}_{\gamma,s} := u_{\gamma,s} - u_{\gamma,s}$ is the centralized version of $u_{\gamma,s}$. For introducing Hoeffding decomposition, we define

\[h_s(X_k) = \mathbb{E} [\Psi_s(X_{k_1}, \ldots, X_{k_m}) | X_k],\]

where $\Psi_s$ are defined in (3.1). Hence, by the Hoeffding decomposition, we decompose $\tilde{u}_{\gamma,s}$ as

\[(B.5) \quad \tilde{u}_{1,s} = \frac{m}{n_1} \sum_{k=1}^{n_1} h_s(X_k) + \binom{n_1}{m}^{-1} \Delta_{n_1,s},\]

\[\quad \tilde{u}_{2,s} = \frac{m}{n_2} \sum_{k=1}^{n_2} h_s(Y_k) + \binom{n_2}{m}^{-1} \Delta_{n_2,s},\]

where we define $\Delta_{n_1,s}$ and $\Delta_{n_2,s}$ as

\[\Delta_{n_1,s} = \sum_{1 \leq k_1 < k_2 < \ldots < k_m \leq n_1} \left( \Psi_s(X_{k_1}, \ldots, X_{k_m}) - \sum_{\ell=1}^{m} h_s(X_{k_\ell}) \right),\]

\[\Delta_{n_2,s} = \sum_{1 \leq k_1 < k_2 < \ldots < k_m \leq n_2} \left( \Psi_s(Y_{k_1}, \ldots, Y_{k_m}) - \sum_{\ell=1}^{m} h_s(Y_{k_\ell}) \right).\]
We then use \( m \sum_{k=1}^{n_1} h_s(X_k)/n_1 \) and \( m \sum_{k=1}^{n_2} h_s(Y_k)/n_2 \) to approximate \( \tilde{u}_{1,s} \) and \( \tilde{u}_{2,s} \). By setting \( \Sigma_1 := (\sigma_{1,st}) \), \( \Sigma_2 := (\sigma_{2,st}) \in \mathbb{R}^{q \times q} \) with

\[
\sigma_{1,st} = E(h_s(X)t(X)) \quad \text{and} \quad \sigma_{2,st} = E(h_s(Y)t(Y)),
\]

considering \( \tilde{v}_{\gamma,s} = m^2 \hat{\sigma}_{\gamma,ss} \), as \( n \to \infty \) we have \( \tilde{v}_{\gamma,s} \to m^2 \sigma_{\gamma,ss} \), which motivates us to define

\[
H^N_s = \left( \frac{1}{n_1} \sum_{k=1}^{n_1} h_s(X_k) - \frac{1}{n_2} \sum_{k=1}^{n_2} h_s(Y_k) \right) / \sqrt{\sigma_{1,ss}/n_1 + \sigma_{2,ss}/n_2}.
\]

Moreover, by setting \( H^N = (H^N_1, \ldots, H^N_q)^\top \), we have that \( H^N \) approximates \( N \), and the approximation error is characterized by the following lemma.

**Lemma B.1.** Assumptions (A), (E), (M1), and (M2) hold. Under \( H_0 \) of (1.8) there is a constant \( C > 0 \) such that as \( n \to \infty \), we have

\[
\mathbb{P}(\|N - H^N\|_{(s_0,p)} > \varepsilon) = o(1),
\]

where \( \varepsilon = C s_0 \log^2(qn)n^{-1/2} \).

The proofs of Lemma B.1 is in Appendix C.1 of supplementary materials. By the definition of \( H^N_s \) in (B.7), \( H^N \) is a sum of random vectors with zero mean and covariance matrix \( R_{12} \), where we set

\[
R_{12} := D_{12}^{-1/2} \Sigma_{12} D_{12}^{-1/2}
\]

with \( \Sigma_{12} = \Sigma_1/n_1 + \Sigma_2/n_2 \) and \( D_{12} = \text{Diag}(\Sigma_{12}) \). Therefore, by the central limit theorem, we can use the Gaussian random vector \( G^N \sim N(0, R_{12}) \) to approximate \( H^N \). To characterize the approximation error, considering

\[
A_z := \{ v, \| v \|_{(s_0,p)} \leq z \} \in A_{s_0},
\]

by Lemma A.1, there is \( \zeta_0 > 0 \) such that

\[
\sup_z \left| \mathbb{P}(\|H^N\|_{(s_0,p)} \leq z) - \mathbb{P}(\|G^N\|_{(s_0,p)} \leq z) \right| \leq C n^{-\zeta_0}
\]

where the constant \( C \) only depends on \( K \) and \( b \). We then use \( G^N \) as the approximation for \( N \).

**Step (ii).** In this step, we aim to obtain the distribution of \( N^b|\mathcal{X}, \mathcal{Y} \). For this, we rewrite \( \tilde{u}_{1,s}^b \) and \( \tilde{u}_{2,s}^b \) in (2.1.3) as

\[
\tilde{u}_{1,s}^b = \frac{m}{n_1} \sum_{k=1}^{n_1} (Q_{1k,s} - \tilde{u}_{1,s})\epsilon_{1,k}^b, \quad \tilde{u}_{2,s}^b = \frac{m}{n_2} \sum_{k=1}^{n_2} (Q_{2k,s} - \tilde{u}_{2,s})\epsilon_{2,k}^b.
\]
where \( Q_{1k,s} \) and \( Q_{2k,s} \) are defined in (2.2). Considering that \( \varepsilon^b_{\gamma,1}, \ldots, \varepsilon^b_{\gamma,n_\gamma} \) are i.i.d. standard normal random variables, therefore given \( \mathcal{X} \) and \( \mathcal{Y} \), \( \hat{u}^b_{\gamma} := (\hat{u}^b_{\gamma,1}, \ldots, \hat{u}^b_{\gamma,q}) \) follows \( N(0, m^2 \tilde{\Sigma}_\gamma / n_\gamma) \) with \( \tilde{\Sigma}_\gamma := (\tilde{\sigma}_{\gamma,st}) \in \mathbb{R}^{q \times q} \) where

(B.12) \[ \tilde{\sigma}_{\gamma,st} = \frac{1}{n_1} \sum_{k=1}^{n_1} (Q_{\gamma k,s} - \hat{u}_{\gamma,s})(Q_{\gamma k,t} - \hat{u}_{\gamma,t}). \]

Apparenty, by the definition of \( \hat{u}_{\gamma,s} \) in (2.1) we have \( \hat{u}_{\gamma,s} = m^2 \tilde{\sigma}_{\gamma,ss} \). Therefore, by setting \( \tilde{\Sigma}_{12} = \tilde{\Sigma}_1 / n_1 + \tilde{\Sigma}_2 / n_2 \) and \( \tilde{D}_{12} = \text{Diag}(\tilde{\Sigma}_{12}) \), we have

\[ N^b| \mathcal{X}, \mathcal{Y} = m^{-1} \tilde{D}_{12}^{-1/2} (\hat{u}^b_1 - \hat{u}^b_2)| \mathcal{X}, \mathcal{Y} \sim N(0, \tilde{R}_{12}), \]

where \( \tilde{R}_{12} = \tilde{D}_{12}^{-1/2} \tilde{\Sigma}_{12} \tilde{D}_{12}^{-1/2} \).

**Step (iii).** In this step, we combine results from previous two steps to justify the bootstrap procedure, i.e., we aim to prove

\[ \sup_{z \in (0, \infty)} \left| \mathbb{P}(N_{(s_0,p)} > z) - \mathbb{P}(N^b_{(s_0,p)} > z| \mathcal{X}, \mathcal{Y}) \right| = o_p(1). \]

For this, we need both the lower and upper bounds of \( \mathbb{P}(N_{(s_0,p)} > z) - \mathbb{P}(N^b_{(s_0,p)} > z| \mathcal{X}, \mathcal{Y}) \). We first present how to obtain the upper bounds. By the triangle inequality, we have

(B.13) \[ \mathbb{P}(\|N\|_{(s_0,p)} > z) \leq \mathbb{P}(\|H^N\|_{(s_0,p)} > z - \epsilon) + \mathbb{P}(\|G^N\|_{(s_0,p)} > \epsilon). \]

By Lemmas B.1, we have \( \rho_1 = o(1) \). We then bound \( \mathbb{P}(\|H^N\|_{(s_0,p)} > z - \epsilon) \). For this, we have

(B.14) \[ \mathbb{P}(\|H^N\|_{(s_0,p)} > z - \epsilon) \leq \rho_2 + \mathbb{P}(\|G^N\|_{(s_0,p)} > z - \epsilon), \]

where \( \rho_2 = \sup_{x > 0} \left| \mathbb{P}(\|H^N\|_{(s_0,p)} > x) - \mathbb{P}(\|G^N\|_{(s_0,p)} > x) \right| \). By (B.10), we have \( \rho_2 \leq C n^{-\gamma_0} \) which yields

(B.15) \[ \mathbb{P}(\|N\|_{(s_0,p)} > z) \leq \mathbb{P}(\|G^N\|_{(s_0,p)} > z - \epsilon) + o(1), \]

as \( n \to \infty \). We then decompose \( \rho_3 \) as \( \rho_3 = \mathbb{P}(\|G^N\|_{(s_0,p)} > z) + \rho_4 \) with

\[ \rho_4 = \mathbb{P}(z - \epsilon < \|G^N\|_{(s_0,p)} \leq z) \]

To control \( \rho_4 \), by utilizing the anti-concentration inequality for the Gaussian random vector in Lemma A.4, we introducing the following lemma.
Lemma B.2. Assumptions (A) and (M1) hold. For any \( z > 0 \) and \( \varepsilon = O(s_0 \log^2(qn)n^{-1/2}) \), we have \( \mathbb{P}(z - \varepsilon < \|G^N\|_{(s_0, p)} \leq z) = o(1) \) as \( n \to \infty \).

The proof of Lemma B.2 is in Appendix C.2 of supplementary materials. By Lemma B.2, we then have

\[
\mathbb{P}(\|N\|_{(s_0, p)} > z) \leq \mathbb{P}(\|G^N\|_{(s_0, p)} > z) + o(1),
\]
as \( n \to \infty \). As is shown in Step (ii), under the null hypothesis we have \( N^b|X, Y \sim N(0, \hat{R}_{12}) \). Considering \( G^N \sim N(0, R_{12}) \), we have

\[
\text{(B.16)} \quad \mathbb{P}(\|N\|_{(s_0, p)} > z) - \mathbb{P}(\|N^b\|_{(s_0, p)} > z|X, Y) \leq \hat{D}_5 + o(1).
\]

The following lemma presents the upper bound of \( \hat{D}_5 \).

Lemma B.3. Assumptions (A), (E), (M1) and (M2) hold. With probability at least \( 1 - C_1 n^{-1} \), we have \( \hat{D}_5 = o_p(1) \) as \( n \to \infty \).

The proof of Lemma B.3 is in Appendix C.3 of supplementary materials. Therefore, we have

\[
\text{(B.17)} \quad \sup_{z > 0} \left( \mathbb{P}(\|N\|_{(s_0, p)} > z) - \mathbb{P}(\|N^b\|_{(s_0, p)} > z|X, Y) \right) = o_p(1),
\]
uniformly for any \( z > 0 \). We can similarly construct the lower bound and obtain

\[
\sup_{z > 0} \left| \mathbb{P}(\|N\|_{(s_0, p)} > z) - \mathbb{P}(\|N^b\|_{(s_0, p)} > z|X, Y) \right| = o_p(1),
\]
which finishes the proof of (3.3) in Theorem 3.1.

\[\square\]

B.3. Proof of Corollary 3.1.

Proof. In Corollary 3.1, we aim to prove (3.11) and (3.12). As the proof of (3.11) is similar, we only prove (3.12). As \( \hat{P}^N_{(s_0, p)} - P^N_{(s_0, p)} \to 0 \) implies \( \mathbb{P}_{H_0}(T^N_{(s_0, p)} = 1) \to \alpha \), for proving (3.12) we only need to prove that as \( n, B \to \infty \), we have

\[
\hat{P}^N_{(s_0, p)} - P^N_{(s_0, p)} \to 0,
\]

\[\text{(B.18)}\]
where $\hat{P}_N^{(s_0,p)}$ is defined in (2.8) and $P_N^{(s_0,p)}$ is the oracle $P$-value of $N_{(s_0,p)}$.

By introducing
\begin{equation}
F_{N,(s_0,p)}(z) = P(\|N\|_{(s_0,p)} \leq z) \quad \text{(B.19)}
\end{equation}
\begin{equation}
\hat{F}_{N,\hat{b},(s_0,p)}(z) = (B + 1)^{-1} \left( \sum_{b=1}^{B} I\{N_{(s_0,p)}^b \leq z|\mathcal{X},\mathcal{Y}\} + 1 \right),
\end{equation}
consider the definitions of $\hat{P}_N^{(s_0,p)}$ and $P_N^{(s_0,p)}$, we have
\begin{equation}
\hat{P}_N^{(s_0,p)} = 1 - \hat{F}_{N,\hat{b},(s_0,p)}(N_{(s_0,p)}) \quad \text{and} \quad P_N^{(s_0,p)} = 1 - F_{N,(s_0,p)}(N_{(s_0,p)}).
\end{equation}

According to Theorems 3.1, under Assumptions (A), (S), (E), (M1), and (M2), by setting $T_1 = |1 - F_{N,\hat{b},(s_0,p)}(N_{(s_0,p)}) - P_N^{(s_0,p)}|$ with
\begin{equation}
F_{N,\hat{b},(s_0,p)}(z) := P(\|N\|_{(s_0,p)} \leq z|\mathcal{X},\mathcal{Y}),
\end{equation}
we have $T_1 \to 0$ as $n \to \infty$. Considering (B.19) and (B.20), we use the triangle inequality to obtain $\left|P_N^{(s_0,p)} - \hat{P}_N^{(s_0,p)}\right| \leq T_1 + T_2$ with
\begin{equation}
T_2 = \left|F_{N,\hat{b},(s_0,p)}(N_{(s_0,p)}) - \hat{F}_{N,\hat{b},(s_0,p)}(N_{(s_0,p)})\right|
\end{equation}

By Massart’s inequality (see Section 1.5 in [10]), we have
\begin{equation}
\sup_{z \in \mathbb{R}} \left|\hat{F}_{N,\hat{b},(s_0,p)}(z) - F_{N,\hat{b},(s_0,p)}(z)\right| \to 0, \quad \text{as } n, B \to \infty.
\end{equation}

Therefore, as $n, B \to \infty$, we have $T_2 \to 0$, which finishes the proof.

\begin{proof}
\end{proof}

B.4. Proof of Theorem 3.3.

Proof. For simplicity, we only consider the two-sample problem. The proof proceeds in two steps. In the first step, we give an upper bound of the oracle critical value
\begin{equation}
t_{\alpha,(s_0,p)}^N = \inf \left\{ t \in \mathbb{R} : P(\|N\|_{(s_0,p)} \leq t|\mathcal{X},\mathcal{Y}) > \alpha \right\}.
\end{equation}

In the second step, with the obtained upper bound of $t_{\alpha,(s_0,p)}^N$, we construct a lower bound of $P(N_{(s_0,p)} > t_{\alpha,(s_0,p)}^N)$. By showing that this lower bound goes to 1 under (3.15), we have
\begin{equation}
P(N_{(s_0,p)} > t_{\alpha,(s_0,p)}^N) \to 1,
\end{equation}

\end{proof}
as \( n, q \to \infty \). Considering that \( \hat{t}^N_{\alpha,(s_0,p)} \) is a bootstrap estimator for \( t^N_{\alpha,(s_0,p)} \), under (3.15) we then have \( \mathbb{P}(N(s_0,p) > \hat{t}^N_{\alpha,(s_0,p)}) \to 1 \), as \( n, B \to \infty \).

**Step (i).** In this step, we give an upper bound of \( t^N_{\alpha,(s_0,p)} \). By the definition of \( N^b \) in (2.5), \( N^b|\mathcal{X}, \mathcal{Y} \) is a \( q \)-dimensional Gaussian random vector with standard normal entries. According to Lemma A.5, by setting \( \sigma = 1 \) and \( t = \sqrt{2\log q} \) we have

\[
(\text{B.23}) \quad \mathbb{E}[\|N^b\|_\infty |\mathcal{X}, \mathcal{Y}] \leq \sqrt{2\log q + \frac{1}{\sqrt{2\log q}}} = \sqrt{2\log q(1 + \{2\log q\}^{-1})}.
\]

By Theorem 5.8 of [4], we have

\[
(\text{B.24}) \quad \mathbb{P}\left(\|N^b\|_\infty \geq \mathbb{E}[\|N^b\|_\infty |\mathcal{X}, \mathcal{Y}] + u|\mathcal{X}, \mathcal{Y}\right) < \exp(-u^2/2).
\]

By setting \( c_\alpha \) as the \( \alpha \)-quantile of \( \|N^b\|_\infty |\mathcal{X}, \mathcal{Y} \), combining (B.23) and (B.24), we have

\[
(\text{B.25}) \quad c_{1-\alpha} \leq \sqrt{2\log q(1 + \{2\log q\}^{-1})} + \sqrt{2\log(1/\alpha)}.
\]

Considering that \( t^N_{\alpha,(s_0,p)} \) is the \( 1-\alpha \) quantile of \( \|N^b\|_{(s_0,p)}|\mathcal{X}, \mathcal{Y} \), by the inequality \( \|N^b\|_{(s_0,p)} \leq s_0^{1/p} \|N^b\|_\infty \), we then have \( t^N_{\alpha,(s_0,p)} \leq s_0^{1/p} c_{1-\alpha} \). Therefore, by (B.25) we have

\[
(\text{B.26}) \quad t^N_{\alpha,(s_0,p)} \leq s_0^{1/p} \left( \sqrt{2\log q(1 + \{2\log q\}^{-1})} + \sqrt{2\log(1/\alpha)} \right).
\]

**Step (ii)** In this step, we aim to obtain an lower bound of \( \mathbb{P}(N(s_0,p) > t^N_{\alpha,(s_0,p)}) \). By (B.26), we have \( \mathbb{P}(N(s_0,p) > t^N_{\alpha,(s_0,p)}) \geq L^N_1 \), where

\[
(\text{B.27}) \quad L^N_1 = \mathbb{P}\left(N(s_0,p) > s_0^{1/p} \left( \sqrt{2\log q(1 + \{2\log q\}^{-1})} + \sqrt{2\log(1/\alpha)} \right) \right).
\]

To obtain the lower bound of \( L^N_1 \), we need some additional notations. By setting \( N_s \) as \( N_s = (\hat{u}_{1,s} - \hat{u}_{2,s})/\sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2} \), in (2.4), we define \( N(s_0,p) = \|N\|_{(s_0,p)} \), where \( N = (N_1, \ldots, N_q)^\top \). Under the alternative hypothesis, \( u_{1,s} = u_{2,s} \) cannot hold for all \( s \in \{1, \ldots, q\} \), which motivates us to define

\[
(\text{B.28}) \quad N^1_s = \frac{\hat{u}_{1,s} - \hat{u}_{2,s} - u_{1,s} + u_{2,s}}{\sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2}} \quad \text{and} \quad N^1 = (N^1_1, \ldots, N^1_q)^\top.
\]
Considering that $\hat{v}_{\gamma,s}$ is the variance estimator for $\sqrt{n} \tilde{u}_{\gamma,s}$ and that $\hat{v}_{\gamma,s}$ has the limit $m^2 \sigma_{\gamma,ss}$ as $n_\gamma \to \infty$, we introduce $\mathbf{D}_2 = (D_{2,1}, \ldots, D_{2,q})^\top$ and $\hat{\mathbf{D}}_2 = (\hat{D}_{2,1}, \ldots, \hat{D}_{2,q})^\top$, where

\begin{align}
D_{2,s} &= |u_{1,s} - u_{2,s}| / \sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2} \\
\hat{D}_{2,s} &= |u_{1,s} - u_{2,s}| / \sqrt{\hat{v}_{1,s}/n_1 + \hat{v}_{2,s}/n_2}.
\end{align}

Without loss of generality, we assume that largest $s_0$ entries of $\mathbf{D}_2$ is $k_1, k_2, \ldots, k_{s_0}$. Therefore, by setting $\mathbf{k} = (k_1, \ldots, k_{s_0})^\top$ under (3.15) we have

\begin{equation}
\|\mathbf{D}_2\|_{(s_0,p)} = \|\mathbf{(D}_2\mathbf{k}\|_p \geq s_0 (1 + \varepsilon_n) \left(\sqrt{2 \log q} + \sqrt{2 \log(1/\alpha)}\right),
\end{equation}

where we set $\varepsilon_n \to 0$ and $\varepsilon_n \sqrt{\log q} \to \infty$ as $n \to \infty$. By the definition of $(s_0, p)$ distance and the triangle inequality, we have

\begin{equation}
N_{(s_0,p)} \geq \|\mathbf{N}_{\mathbf{k}}\|_p \geq \|\mathbf{(D}_2\mathbf{k}\|_p - \|\mathbf{N}_{\mathbf{k}}\|_p.
\end{equation}

As we impose conditions on $\mathbf{D}_2$ not on $\hat{\mathbf{D}}_2$, by the definitions of $\mathbf{D}_2$ and $\hat{\mathbf{D}}_2$ in (B.29) we need the estimation error of $\hat{v}_{\gamma,s}$. By Lemme A.6, considering Assumption (M1), for $m > 1$, with probability at least $1 - C_1/n^{-1}$, we have

\begin{equation}
\max_{\gamma=1,2, s=1,\ldots,q} \left| \sqrt{\frac{\hat{v}_{\gamma,s}}{m^2 \sigma_{\gamma,ss}}} - 1 \right| \leq C \frac{\log^{3/2}(qn)}{\sqrt{n}},
\end{equation}

when $n$ is sufficiently large. Similarly, for $m = 1$ and sufficiently large $n$ with probability at least $1 - C_1/n^{-1}$ we have

\begin{equation}
\max_{\gamma=1,2, s=1,\ldots,q} \left| \sqrt{\frac{\hat{v}_{\gamma,s}}{\sigma_{\gamma,ss}}} - 1 \right| \leq C \frac{\log(qn)}{n} + C \frac{\log^2(qn)}{n}.
\end{equation}

Therefore, we introduce the event $\mathcal{E}_0(x)$ as

\begin{equation}
\mathcal{E}_0(x) = \left\{ \max_{\gamma=1,2, s=1,\ldots,q} \left| \sqrt{\frac{\hat{v}_{\gamma,s}}{m^2 \sigma_{\gamma,ss}}} - 1 \right| \leq x \right\}.
\end{equation}

We set $x \propto \log^{3/2}(qn)/\sqrt{n}$ for $m > 1$ and $x \propto \sqrt{\log(qn)/n + \log^2(qn)/n}$ for $m = 1$. We then have $\mathbb{P}(\mathcal{E}_0(x)^c) \leq n^{-1}$. By (B.31), under $\mathcal{E}_0(x)$ we have

\begin{equation}
N_{(s_0,p)} \geq \frac{1}{1 + x} \|\mathbf{D}_2\|_{(s_0,p)} - \|\mathbf{N}_{\mathbf{k}}\|_p.
\end{equation}
Therefore, by partitioning the event based on $\mathcal{E}_0(x)$, we use (B.34) to obtain

$$L_1^N \geq \mathbb{P}\left(L_2^N > s_0(1 + \{2 \log q\}^{-1}) \left(\sqrt{2 \log q + \sqrt{2 \log(1/\alpha)}}\right), \mathcal{E}_0(x)\right).$$

Considering (B.30), by choosing $u$ satisfying $(1 + (1 + x)(1 + u + \{2 \log q\}^{-1})) = (1 + \varepsilon_n)$ we have

(B.35) $$L_1^N \geq \mathbb{P}\left(\|\mathbf{N}_1\|_p < s_0 u \sqrt{2 \log q}\right).$$

By the triangle inequality, for $i \in \{1, \ldots, s_0\}$ we have

(B.36) $$\mathbb{P}\left(\|\mathbf{N}_k\|_p \geq s_0 u \sqrt{2 \log q}\right) \leq s_0 \max_{1 \leq i \leq s_0} \mathbb{P}\left(|\mathbf{N}_k| \geq u \sqrt{2 \log q}\right).$$

Therefore, combining (B.35) and (B.36) we have

$$L_1^N \geq 1 - \mathbb{P}\left(\|\mathbf{N}_k\|_p \geq s_0 u \sqrt{2 \log q}\right) \geq 1 - s_0 \max_{1 \leq i \leq s_0} \mathbb{P}\left(|\mathbf{N}_k| \geq u \sqrt{2 \log q}\right).$$

By the definition of $L_1$ in (B.27), to prove $L_1 \to 1$ we only need to obtain

(B.37) $$s_0 \mathbb{P}\left(|\mathbf{N}_k| \geq u \sqrt{2 \log q}\right) \to 0,$$

uniformly as $n, q \to \infty$. For this, we introduce the following lemma.

**Lemma B.4.** Under Assumptions $(A)'$, $(E)$, $(M_1)$, and $(M_2)$, as $n, q \to \infty$, we have

(B.38) $$s_0 \max_{s=1, \ldots, q} \mathbb{P}\left(|\mathbf{N}_s| \geq u \sqrt{2 \log q}\right) \to 0.$$

The detailed proof of Lemma B.4 is in Appendix C.4 of supplementary materials. By Lemma B.4, we finish the proof.

**B.5. Proof of Theorem 3.5.**

**Proof.** In Theorem 3.5, we aim to prove (3.18) and (3.19). As the proof of (3.18) is similar, we only prove (3.19). The proof proceeds in two steps. In the first step, by setting $\bar{F}_{N,\text{ad}}(z) = \mathbb{P}(N_{\text{ad}} \leq z|\mathcal{X}, \mathcal{Y})$ and $\bar{F}_{N,\text{ad}}^{\uparrow}(z) = \mathbb{P}(\bar{N}_{\text{ad}} \leq z)$, we prove that as $n, B \to \infty$, we have

(B.39) $$\bar{F}_{N,\text{ad}}(\bar{N}_{\text{ad}}) - \bar{F}_{N,\text{ad}}(N_{\text{ad}}) \to 0,$$
where $N_{ad}$ and $\tilde{N}_{ad}$ are defined in (3.16) and (3.17). In the second step, we prove that

$$F_{N,ad}(N_{ad}) - \hat{P}_{ad}^N \to 0,$$

as $n, B \to \infty$. Combining (B.39) and (B.40), we can easily obtain (3.19).

**Step (i).** In this step, we aim to prove (B.39). For this, we need the following lemma to analyze the difference between the cumulative distribution functions of $N_{ad}$ and $\tilde{N}_{ad}$.

**Lemma B.5.** Assumptions (A)$''$, (E), (M1) and (M2) hold. Under $H_0$ of (1.8), we have that for any $\epsilon > 0$

$$\sup_{z \in [\epsilon, 1 - \epsilon]} \left| F_{N,ad}(z) - \tilde{F}_{N,ad}(z) \right| = 0,$$

as $n, B \to \infty$.

The proof of Lemma B.5 is in Appendix C.5 of supplementary materials.

After introducing Lemma B.5, we then prove (B.39). In detail, we aim to prove that for any $\delta, \epsilon' > 0$ we have

$$\Delta_1 \leq \Delta_2 + \Delta_3,$$

where

$$\Delta_2 = \mathbb{P}\left( \left| \tilde{F}_{N,ad}(\tilde{N}_{ad}) - F_{N,ad}(\tilde{N}_{ad}) \right| \geq \delta/2 \right),$$

$$\Delta_3 = \mathbb{P}\left( \left| F_{N,ad}(\tilde{N}_{ad}) - F_{N,ad}(N_{ad}) \right| \geq \delta/2 \right).$$

We then separately bound $\Delta_2$ and $\Delta_3$. To prove (B.42). We only need to show both $\Delta_2 < \epsilon'/2$ and $\Delta_3 < \epsilon'/2$ hold as $n$ and $B$ are sufficiently large. For $\Delta_2$, by setting $\mathcal{E}_{\tilde{N}_{ad}}(\epsilon) := \{\tilde{N}_{ad} \in [\epsilon, 1 - \epsilon]\}$, we can bound $\Delta_2$ by

$$\Delta_2 \leq \mathbb{P}\left( \left| \tilde{F}_{N,ad}(\tilde{N}_{ad}) - F_{N,ad}(\tilde{N}_{ad}) \right| \geq \delta/2 \cap \mathcal{E}_{\tilde{N}_{ad}}(\epsilon) \right) + \Delta_4,$$

where $\Delta_4 = \mathbb{P}((\mathcal{E}_{\tilde{N}_{ad}}(\epsilon))^c)$. By the definition of $\tilde{N}_{ad}$ in (3.17), by choosing $\epsilon$ small enough, we have $\Delta_4 \leq \epsilon'/4$. By Lemma B.5 and the definition of $\mathcal{E}_{\tilde{N}_{ad}}(\epsilon)$, we also have

$$\mathbb{P}\left( \left| \tilde{F}_{N,ad}(\tilde{N}_{ad}) - F_{N,ad}(\tilde{N}_{ad}) \right| \geq \delta/2 \cap \mathcal{E}_{\tilde{N}_{ad}}(\epsilon) \right) \leq \epsilon'/4,$$
for sufficiently large $n$ and $B$. Hence, we have $\Delta_2 \leq \epsilon'/2$ holds as $n$ and $B$ are sufficiently large. After the proof for $\Delta_2$, we then bound $\Delta_3$. By the definition of $\tilde{N}_{ad}$ in (3.17) and Corollary 3.1, we have

\[ |\tilde{N}_{ad} - N_{ad}| \to 0, \quad \text{as } n, B \to \infty. \] (B.46)

Therefore, we obtain that $f_{N,ad}(z) = F'_{N,ad}(z)$ is uniformly bounded for sufficiently large $n, B$. Hence, there is a constant $C$ such that

\[ |F_{N,ad}(\tilde{N}_{ad}) - F_{N,ad}(N_{ad})| \leq C|\tilde{N}_{ad} - N_{ad}|. \] (B.47)

Combining (B.43), (B.46), and (B.47), we have $\Delta_3 \leq \epsilon'/2$ for sufficiently large $n$ and $B$. Therefore, we finish the proof of (B.39).

**Step (ii).** In this step, we aim to prove (B.40). For this, we introduce

\[ F_{N^b,(s_0,p)} = \mathbb{P}(N_{(s_0,p)}^b \leq z|\mathcal{X}, \mathcal{Y}), \]

where $N_{(s_0,p)}^b$ is defined in (2.6). Therefore, we define the cumulation distribution function of $N_{ad}^b|\mathcal{X}, \mathcal{Y}$ as

\[ F_{N^b,ad}(z) = \mathbb{P}(N_{ad}^b \leq z|\mathcal{X}, \mathcal{Y}). \] (B.49)

Considering the definition of $\hat{P}_{ad}^N$ in (2.13), by setting

\[ \hat{F}_{N,ad'}(z) = \left( \sum_{b=1}^{B} \mathbb{I}(N_{ad'}^b \leq z|\mathcal{X}, \mathcal{Y}) + 1 \right)/(B + 1), \] (B.50)

we have $\hat{P}_{ad}^N = \hat{F}_{N,ad'}(N_{ad})$.

To prove $F_{N,ad}(N_{ad}) - \hat{F}_{N,ad'}(N_{ad}) \to 0$, by plugging in $F_{N^b,ad}(N_{ad})$ and using the triangle inequality, it is sufficient to prove

\[ F_{N,ad}(N_{ad}) - F_{N^b,ad}(N_{ad}) \to 0 \quad \text{and} \quad F_{N^b,ad}(N_{ad}) - \hat{P}_{ad}^N \to 0, \] (B.51)

as $n, B \to \infty$. To prove (B.51), we introduce the following two lemmas.

**Lemma B.6.** Assumptions (A)'', (E), (M1), and (M2) hold. Under $H_0$ of (1.8), by setting $F_{N,ad}(z) = \mathbb{P}(N_{ad} \leq z|\mathcal{X}, \mathcal{Y})$ and $F_{N^b,ad}(z) = \mathbb{P}(N_{ad}^b \leq z|\mathcal{X}, \mathcal{Y})$, we have

\[ \sup_{z \in [\epsilon, 1-\epsilon]} |F_{N,ad}(z) - F_{N^b,ad}(z)| \to 0, \quad \text{as } n, B \to \infty, \] (B.52)

for any $\epsilon > 0$. 
LEMMA B.7. For any \( \epsilon > 0 \), we have that as \( n, B \to \infty \),

\[
\sup_{z \in [\epsilon, 1 - \epsilon]} |F_{N_b, ad}(z) - \hat{F}_{N, ad}(z)| \to 0,
\]

where \( \hat{F}_{N, ad}(z) \) is defined in (B.50).

The proofs of Lemmas B.6 and B.7 are in Appendices C.6 and C.7 of supplementary materials. Let \( \mathcal{E}_{N, ad}(\epsilon) = \{ N_{ad} \in [\epsilon, 1 - \epsilon] \} \). Considering Lemmas B.6 and B.7, by replacing \( \mathcal{E}_{N, ad}(\epsilon) \) with \( \mathcal{E}_{N, ad} \), similarly to (B.44) and (B.45) we can prove (B.51), which finishes the proof of Theorem 3.5.

PROOF. For \( G \sim N(0, \mathbf{R}) \in \mathbb{R}^q \) with \( q \geq 1 \) fixed, the distribution of \( \|G\|_{(s_0,p)} \) is absolutely continuous with respect to the Lebesgue measure and its density function \( f_{G(p, p)} \) is positive everywhere. This implies that for any \( \epsilon > 0 \), \( \min_{\mathcal{G}} f_{(s_0, p), z \leq \epsilon \leq z} \leq f_{(s_0, p)}(z) > 0 \). To prove the result after taking infimum over all positive integers \( q \), it suffices to show that as long as \( \mathbf{R} \in \mathcal{R} \), the limiting distribution of \( \|G\|_{(s_0, p)} \) as \( q \to \infty \) exists with an absolutely continuous density function. For this, we prove a stronger result, which characterizes the joint asymptotic distribution of the top \( s_0 \) order statistics of weakly dependent standard normal random variables. In detail, let \( v^{(1)}, v^{(2)}, \ldots, v^{(q)} \) be an ascending sequence of the magnitudes of the coordinates of \( \mathbf{v} \in \mathbb{R}^q \) such that \( 0 = v^{(1)} < v^{(2)} \leq \cdots \leq v^{(q)} \). Set \( G = (G_1^1, \ldots, G_q^1) \sim N(0, \mathbf{R}) \) with \( \mathbf{R} \in \mathcal{R} \) and \( G^I = (G_1^I, \ldots, G_q^I)^\top \sim N(0, \mathbf{I}_q) \). Moreover, let \( \varphi_j(G) = G^{q-j+1} \) for \( j = 1, \ldots, q \) and \( a_q = 2 \log q - \log(\log q) \). For any \( \mathbf{x} = (x_1, x_2, \ldots, x_{s_0}) \) with \( x_1 > x_2 > \cdots > x_{s_0} > 0 \), by setting \( f_{ext}(t_1, \ldots, t_{s_0}) = \exp \left( -\frac{1}{2} \sum_{j=1}^{s_0-1} t_j \right) g(t_{s_0}) I(t_1 > t_2 > \cdots > t_{s_0}) \), where \( g(t) = 2^{-\frac{1}{2} - \frac{1}{2}} \exp(-t/2 - t^{1/2} e^{-t/2}) \), we shall prove that as \( q \to \infty \),

\[
\mathbb{P}\left( \varphi^2_1(G) \leq x_1 + a_q, \ldots, \varphi^2_{s_0}(G) \leq x_{s_0} + a_q \right)
\]

\[
\longrightarrow \left( \frac{1}{2 \sqrt{\pi}} \right)^{s_0-1} \int_{-\infty}^{x_1} \cdots \int_{-\infty}^{x_{s_0}} f_{ext}(t_1, \ldots, t_{s_0}) \, dt_{s_0} \cdots dt_1,
\]

holds uniformly for \( \mathbf{R} \in \mathcal{R} \).

For simplicity, we only prove (B.54) for \( s_0 = 2 \), as the general case can be
dealt with similarly. Let \( y_{jq} = \sqrt{x_j + a_q} \) for \( j = 1, 2 \), and note

\[
\{ \varphi_1(G) > \sqrt{x_1 + a_q}, \varphi_2(G) > \sqrt{x_2 + a_q} \}
\]

\[
= \bigcup_{1 \leq i \neq j \leq q} \{ (|G_i||G_j|) > (y_{1q}, y_{2q}) \} = \bigcup_{k=1}^{2q} \{ (|G_{ik}||G_{jk}|) > (y_{1q}, y_{2q}) \},
\]

where \( \{(i_k, j_k)\}_{k=1}^{2q} = \{(1, 2), (1, 3), \ldots, (1, q), (2, 1), (2, 3), \ldots, (2, q), \ldots, (q, q-1)\} \) and \( \bar{q} = q(q-1)/2 \). By the Bonferroni inequality, for any fixed \( k < \bar{q} \), we have

\[
\sum_{\ell=1}^{2k} (-1)^{\ell-1} E_{\ell} \leq \mathbb{P}(\varphi_1(G) > \sqrt{x_1 + a_q}, \varphi_2(G) > \sqrt{x_2 + a_q})
\]

\[
\leq \sum_{\ell=1}^{2k-1} (-1)^{\ell-1} E_{\ell},
\]

where

\[
E_{\ell} = \sum_{1 \leq k_1 < \cdots < k_{\ell} \leq 2q} \mathbb{P}\left( |G_{ik_1}| > y_{1q}, |G_{jk_{\ell}}| > y_{2q}, \ldots, |G_{ik_{\ell}}| > y_{1q}, |G_{jk_1}| > y_{2q} \right).
\]

Moreover, for every \( 2 \leq t \leq 2\ell \), define

\[
E_{\ell,t} = \sum_{1 \leq k_1 < \cdots < k_{\ell} \leq 2q} \mathbb{P}\left( \min_{1 \leq \nu \leq \ell} |G_{ik_{\nu}}| > y_{1q}, \min_{1 \leq \nu \leq \ell} |G_{jk_{\nu}}| > y_{2q} \right).
\]

We define index sets \( I^c, I, \) and \( I_k \) in the same way as in the proof of Lemma 6 in [6]. Therefore, we have \( I = \bigcup_{k=1}^{t-1} I_k \). Further, for \( 1 \leq i_1 < \cdots < i_t \leq q \), by defining

\[
Q(i_1, \ldots, i_t) = \{ 1 \leq k_1 < \cdots < k_{\ell} \leq 2q : \{i_{k_1}, j_{k_1}, \ldots, i_{k_\ell}, j_{k_\ell}\} = \{i_1, \ldots, i_t\} \},
\]

with \( \#Q(i_1, \ldots, i_t) \leq (t(t-1)) \), we have

\[
E_{\ell,t} = \sum_{(i_1, \ldots, i_t) \in I^c} \sum_{(k_1, \ldots, k_{\ell}) \in Q(i_1, \ldots, i_t)} P_{k_1, \ldots, k_{\ell}} + \sum_{(i_1, \ldots, i_t) \in I} \sum_{(k_1, \ldots, k_{\ell}) \in Q(i_1, \ldots, i_t)} P_{k_1, \ldots, k_{\ell}}.
\]

For \( (k_1, \ldots, k_{\ell}) \in Q(i_1, \ldots, i_t) \) with \( (i_1, \ldots, i_t) \in I^c \), a straightforward adaptation of the arguments used to prove (20) in [6] yields that, as \( q \to \infty \),

\[
P_{k_1, \ldots, k_{\ell}} = (1 + o(1)) P^I_{k_1, \ldots, k_{\ell}},
\]

(B.57)
where $P_{k_1,\ldots,k_t}^I$ is defined in the same way as $P_{k_1,\ldots,k_t}$ in (B.56) by replacing $G_i$ with $G_i^I$.

For $(k_1,\ldots,k_t) \in Q(i_1,\ldots,i_t)$ with $(i_1,\ldots,i_t) \in \mathcal{I}_k$ for some $1 \leq k \leq t-1$, considering $y_{1q} > y_{2q}$, we have

$$P_{k_1,\ldots,k_t} \leq \mathbb{P}(|G_{i_1}| > y_{2q}, \ldots, |G_{i_t}| > y_{2q}) := \tilde{P}_{i_1,\ldots,i_t}.$$ \hfill (B.58)

Now, it follows from (21) in [6] with slight modification that, as $q \to \infty$,

$$M_2(\ell,t) \leq \sum_{(i_1,\ldots,i_t) \in \mathcal{I}} \left( \begin{array}{c} t(t-1) \\ \ell \end{array} \right) \tilde{P}_{i_1,\ldots,i_t} = \left( \begin{array}{c} t(t-1) \\ \ell \end{array} \right) \sum_{(i_1,\ldots,i_t) \in \mathcal{I}} \tilde{P}_{i_1,\ldots,i_t} \to 0.$$ \hfill (B.58)

We define $M_2^I(\ell,t)$ by replacing entries of $G$ with the corresponding entries of $G^I$ in $M_2(\ell,t)$. Similarly to (B.58), we have $M_2^I(\ell,t) = o(1)$ as $q \to \infty$. Therefore, as $q \to \infty$, we have

$$E_\ell = \sum_{t=2}^{2\ell} E_{\ell,t} = \{1 + o(1)\} \sum_{1 \leq k_1 < \cdots < k_t \leq 2q} P_{k_1,\ldots,k_t}^I + o(1).$$

This, together with (B.55) implies that, as $q \to \infty$,

$$\{1 + o(1)\} \sum_{\ell=1}^{2k} (-1)^{\ell-1} \sum_{1 \leq k_1 < \cdots < k_t \leq 2q} P_{k_1,\ldots,k_t}^I + o(1) \leq \mathbb{P}\left( \varphi_1(G^I) > \sqrt{x_1 + a_q}, \varphi_2(G^I) > \sqrt{x_2 + a_q} \right) \leq \{1 + o(1)\} \sum_{\ell=1}^{2k-1} (-1)^{\ell-1} \sum_{1 \leq k_1 < \cdots < k_t \leq 2q} P_{k_1,\ldots,k_t}^I + o(1).$$ \hfill (B.59)

On the other hand, observing

$$\mathbb{P}\left( \varphi_1(G^I) > \sqrt{x_1 + a_q}, \varphi_2(G^I) > \sqrt{x_2 + a_q} \right) = \lim_{k \to \infty} \sum_{\ell=1}^{2k} (-1)^{\ell-1} \sum_{1 \leq k_1 < \cdots < k_t \leq 2q} P_{k_1,\ldots,k_t}^I,$$

and $a_q = 2 \log q - \log(\log q)$, by [8], the bivariate vector $(\varphi_1^2(G^I) - a_q, \varphi_2^2(G^I) - a_q)$ has a limiting distribution with joint density function

$$g_2(t_1,t_2) = g(t_1)g(t_2) \quad \frac{e^{-\frac{t_1}{2}}}{2\sqrt{\pi}} g(t_2), \quad \text{for} \quad t_1 > t_2,$$

where $G(t) = \exp(-\pi^{-1/2}e^{-t/2})$ and $g(t) = G'(t)$. Therefore, the limit in (B.60) is equal to $\int_{x_1}^{\infty} \int_{x_2}^{\infty} g_2(t_1,t_2) I(t_1 > t_2) dt_2 dt_1$, which together with (B.59) proves (B.54) by letting $q \to \infty$ first and then $k \to \infty$. \hfill $\square$
B.7. Proof of Theorem 3.7.

**Proof.** For simplicity, we only consider the two-sample problem. In detail, we aim to prove

\[(B.61) \quad \mathbb{P}_{H_1}(T_{ad}^N = 1) \to 1, \quad \text{as } n, B \to \infty.\]

under (3.21) and some assumptions. By the definition of $T_{ad}^N$ in (2.14), for proving (B.61), it is equivalent to prove

\[(B.62) \quad \mathbb{P}_{H_1}(\hat{P}_{ad}^N \leq \alpha) \to 1, \quad \text{as } n, B \to \infty.\]

By the definition of $\hat{P}_{ad}^N$ and $\hat{F}_{N,ad'}(z)$ in (2.13) and (B.50), (B.62) becomes

\[(B.63) \quad \mathbb{P}_{H_1}(\hat{F}_{N,ad'}(N_{ad}) < \alpha) \to 1, \quad \text{as } n, B \to \infty.\]

Therefore, to obtain (B.61), it is sufficient to prove (B.63). By setting $\alpha' = \alpha / \# \{P\}$, we can prove that $\alpha$ is also an upper bound of $\hat{F}_{N,ad'}(\alpha')$, i.e.,

\[(B.64) \quad \mathbb{P}_{H_1}(\hat{F}_{N,ad'}(\alpha') \leq \alpha) \to 1, \quad \text{as } n, B \to \infty.\]

By (B.64), to obtain (B.63) it is sufficient to prove

\[(B.65) \quad \mathbb{P}_{H_1}(N_{ad} \leq \alpha') \to 1, \quad \text{as } n, B \to \infty.\]

By the definition of $N_{ad}$ in (2.10), we have

\[(B.66) \quad \mathbb{P}_{H_1}(\hat{P}_{(s_0,p)}^N \leq \alpha') \leq \mathbb{P}_{H_1}(N_{ad} \leq \alpha'),\]

for any $p \in P$. By Theorem 3.3, under (3.21) we have

\[(B.67) \quad \mathbb{P}_{H_1}(\hat{P}_{(s_0,p)}^N \leq \alpha') \to 1, \quad \text{as } n, B \to \infty.\]

Combining (B.66) and (B.67), we prove (B.65).

To complete the proof, we now prove (B.64). By Lemma B.7, for any $0 < \alpha < 1$, we have

\[(B.68) \quad \mathbb{P}(\hat{F}_{N,ad'}(\alpha') \leq \alpha) = \mathbb{P}(F_{N^b,ad}(\alpha') \leq \alpha), \quad \text{as } n, B \to \infty.\]

Moreover, by the definition of $F_{N^b,ad}(z)$ in (B.49), we have that $F_{N^b,ad}(\alpha') \leq \alpha$ holds with probability 1, which yields (B.64). \qed
APPENDIX C: PROOF OF LEMMAS IN APPENDIX B

C.1. Proof of Lemma B.1.

PROOF. To prove Lemma B.1, we need to bound \( \mathbb{P}(\|N - H^N\|_{(s_0,p)} > \varepsilon) \), where \( \varepsilon = C_s0 \log^2(qn) n^{-1/2} \). We first prove for \( m \geq 1 \). For this, we set \( \hat{H}^N = (\hat{H}^N_1, \ldots, \hat{H}^N_t) \) with

\[
\hat{H}^N_s = \left( \frac{1}{n_1} \sum_{k=1}^{n_1} h_s(X_k) - \frac{1}{n_2} \sum_{k=1}^{n_2} h_s(Y_k) \right) / \sqrt{\hat{\sigma}_{1,ss}/n_1 + \hat{\sigma}_{2,ss}/n_2}.
\]

(C.1) By plugging \( \hat{H}^N \), we have \( \mathbb{P}(\|N - H^N\|_{(s_0,p)} > \varepsilon) \leq D_1 + D_2 \) with

\[
D_1 = \mathbb{P}(\|\hat{H}^N\|_{(s_0,p)} > \varepsilon/2), \quad D_2 = \mathbb{P}(\|\hat{H}^N - H^N\|_{(s_0,p)} > \varepsilon/2).
\]

Therefore, we only need to separately prove \( D_1 = o(1) \) and \( D_2 = o(1) \) as \( n \to \infty \).

For proving \( D_1 = o(1) \), by setting \( \varepsilon_{12} := \{\min_{s,\gamma} \hat{\sigma}_{\gamma,ss} > b/2\} \), we have

\[
D_1 \leq \mathbb{P}(\|N - \hat{H}^N\|_{(s_0,p)} > \varepsilon/2 \cap \varepsilon_{12}) + \mathbb{P}(\varepsilon_{12}^c).
\]

(C.2) Considering Assumptions (A) and (M1), by Lemma A.6, we have \( \mathbb{P}(\varepsilon_{12}^c) = o(1) \) as \( n \to \infty \). Hence, we only need to prove \( I_1 = o(1) \) as \( n \to \infty \). By the Hoeffding’s decomposition, considering \( \hat{\sigma}_{\gamma,ss} = m^2 \hat{\sigma}_{\gamma,ss} \) and \( \|v\|_{(s_0,p)} \leq s_0^{1/p} \|v\|_\infty \), we have

\[
I_1 \leq \mathbb{P} \left( \max_{1 \leq s \leq q} \left| \left( \frac{n_1}{m} \right)^{-1} \Delta_{n_1,ss} - \left( \frac{n_2}{m} \right)^{-1} \Delta_{n_2,ss} \right| > \frac{mb^{1/2} \varepsilon}{\sqrt{2s_0^{1/p}}} \sqrt{ \frac{1}{n_1} + \frac{1}{n_2} } \right),
\]

where \( \Delta_{n_1,ss} \) and \( \Delta_{n_2,ss} \) are residuals of the Hoeffding’s decomposition. For bounding the residuals, we threshold the kernel by \( B_n = C \log(qn) \). For this, we introduce

\[
V_{1,s}^{i_1,\ldots,i_m} = \Psi_s(X_{i_1}, \ldots, X_{i_m}) \mathbb{I}\{\|\Psi_s(X_{i_1}, \ldots, X_{i_m})\| \leq B_n\}, \quad E_{1,s} = \mathbb{E}\left(\Psi_s(X_{i_1}, \ldots, X_{i_m}) \mathbb{I}\{\|\Psi_s(X_{i_1}, \ldots, X_{i_m})\| \leq B_n\}\right),
\]

(C.3) and denote the thresholded kernel and Hoeffding’s projection by

\[
\hat{\Psi}_s(X_{i_1}, \ldots, X_{i_m}) = V_{1,s}^{i_1,\ldots,i_m} - E_{1,s},
\]

\[
\hat{h}_s(X_i) = \mathbb{E}\left(\hat{\Psi}_s(X_{i_1}, \ldots, X_{i_m}) | X_i\right).
\]

(C.4)
Hence, the corresponding residuals become
\[
\hat{\Delta}_{n_1,s} = \sum_{1 \leq i_1 < \ldots < i_m \leq n_1} \left( \hat{\Psi}_s(X_{i_1}, \ldots, X_{i_m}) - \sum_{\ell} \hat{h}_s(X_{i_\ell}) \right),
\]

By the definitions of both $\Delta_{n_1,s}$ and $\hat{\Delta}_{n_1,s}$, we then have
\[
|\Delta_{n_1,s} - \hat{\Delta}_{n_1,s}| \leq \Delta_{n_1,s} - \left( \sum_{1 \leq i_1 < \ldots < i_m \leq n_1} V_{1,s}^{i_1,\ldots,i_m} - \sum_{\ell} \mathbb{E}(V_{1,s}^{i_1,\ldots,i_m}|X_{i_\ell}) \right)
+ (m - 1) \binom{n_1}{m} |E_{1,s}|.
\]

Considering that $\varepsilon = Cs_0 \log^2(qn)n^{-1/2}$, we have
\[
\frac{mb^{1/2}\varepsilon}{\sqrt{2}s_0^{1/p}} \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} = O(\log^2(qn)/n).
\]

By choosing a proper constant $C$ in $B_n$, considering Assumption (E), we have $\max_s(|E_{1,s}| + |E_{2,s}|) < \log^2(qn)/n$. Hence, when $n$ is sufficiently large, we use the triangle inequality to get $I_1 \leq I_{1,1} + I_{1,2}$, where
\[
I_{1,1} = P \left( \max_{1 \leq s \leq q} \left| \binom{n_1}{m}^{-1} \Delta_{n_1,s} - \binom{n_2}{m}^{-1} \hat{\Delta}_{n_2,s} \right| > C\frac{\log^2(qn)}{n} \right)
\]
\[
I_{1,2} = Cqn^m \max_{s,i_1,\ldots,i_m} \left( \mathbb{P}(|\Psi_s(X_{i_1}, \ldots, X_{i_m})| > B_n) + \mathbb{P}(|\Psi_s(Y_{j_1}, \ldots, Y_{j_m})| > B_n) \right)
\]

By choosing a proper constant $C$ in $B_n$, considering Assumption (E), we have $I_{1,2} = o(1)$. For $I_{1,1}$, by Proposition 2.3 (c) in [1], we obtain

\[
I_{1,1} \leq Cq \exp \left( -Cn^{1 - \frac{2}{m}} \log^2(qn) \right).
\]

Considering $m \geq 2$ and Assumption (A), we then have $I_{1,1} = o(1)$. Therefore, we prove that $D_1 = o(1)$, as $n \rightarrow \infty$.

After the proof for $D_1$, we then prove that $D_2 = o(1)$. Considering

\[
\|\hat{H}^N - H^N\|_{(s_0,p)} \leq s_0^{1/p} \|\hat{H}^N - H^N\|_{\infty},
\]
we have $D_2 \leq \mathbb{P}(\|\hat{H}^N - H^N\|_{\infty} > 0.5s_0^{1/p}\varepsilon)$. By the definitions of $H^N$ and $\hat{H}^N$ in (B.7) and (C.1), we have $\|\hat{H}^N - H^N\|_{\infty} \leq I_2I_3$ with
\[
I_2 = \max_{1 \leq s \leq q} \left| \sum_{k=1}^{n_1} h_s(X_k) - \rho \sum_{k=1}^{n_2} h_s(Y_k) \right| \sqrt{n_1\sigma_{1,ss} + \rho^2n_2\sigma_{2,ss}},
\]
\[
I_3 = \max_{1 \leq s \leq q} \left| 1 - \sqrt{\frac{\sigma_{1,ss} + \rho\sigma_{2,ss}}{\sigma_{1,ss} + \rho\sigma_{2,ss}}} \right|,
\]
where \( \rho = n_1/n_2 \). By Assumption (E) and exponential inequality, we have that \( I_2 \leq C \sqrt{\log(qn)} \) holds with probability \( 1 - C_1 n^{-1} \).

For bounding \( I_3 \), we introduce the following lemma.

**Lemma C.1.** \( \xi_1, \ldots, \xi_s \in \mathbb{R} \) are positive random variables with \( \xi_s > 0 \). For \( y \in (0,1] \), we have

\[
P \left( \max_{1 \leq s \leq q} |1 - \xi_s| \leq y/2 \right) \leq P \left( \max_{1 \leq s \leq q} |1 - \xi_s^{-1}| \leq y \right).
\]

The detailed proof of Lemma C.1 is in Appendix D.1. Motivated by Lemma C.1, we introduce

\[
I'_3 := \max_{1 \leq s \leq q} \left| 1 - \frac{\sqrt{\hat{\sigma}_{1,ss} + \rho \hat{\sigma}_{2,ss}}}{\sqrt{\sigma_{1,ss} + \rho \sigma_{2,ss}}} \right|
\]

By Assumption (M1), considering \((a + b)(a - b) = a^2 - b^2\), we use the triangle inequality to obtain

\[
I'_3 \leq \max_{1 \leq s \leq q} (\sigma_{1,ss} + \rho \sigma_{2,ss})^{-1} \left| \frac{\hat{\sigma}_{1,ss} + \rho \hat{\sigma}_{2,ss} - \sigma_{1,ss} - \rho \sigma_{2,ss}}{\sqrt{\sigma_{1,ss} + \rho \sigma_{2,ss}}} \right|
\]

\[
\leq (1 + \rho)^{-1} b^{-1} \left( \max_{1 \leq s \leq q} |\hat{\sigma}_{1,ss} - \sigma_{1,ss}| + \rho \max_{1 \leq s \leq q} |\hat{\sigma}_{2,ss} - \sigma_{2,ss}| \right).
\]

Therefore, by Lemma A.6, \( I'_3 \leq C \log^{3/2}(qn) n^{-1/2} \) holds with probability \( 1 - C_1 n^{-1} \). By Lemma C.1, we then have that \( I_3 \leq C \log^{3/2}(qn) n^{-1/2} \) holds with probability \( 1 - C_1 n^{-1} \) for sufficiently large \( n \). Combining (C.6) and the bound for \( I_2 \) and \( I_3 \), we then have

\[
\| \widehat{H}^N - H^N \|_{(s_0,p)} \leq C s_0 \frac{\log^2(qn)}{\sqrt{n}}
\]

with probability \( 1 - C_1 n^{-1} \) for sufficiently large \( n \). Therefore, we have \( D_2 = o(1) \) as \( n \to \infty \), which finishes the proof for \( m > 1 \).

By Lemma A.6 and similar proof, we can also prove for \( m = 1 \). As the proof is much easier and similar to the proof for \( m > 1 \), we omit the proof here.

**C.2. Proof of Lemma B.2.**

**Proof.** For notational simplicity, we set

\[
L_{z,\varepsilon} := P \left( \| G \|_{(s_0,p)} \leq z + \varepsilon \right) - P \left( \| G \|_{(s_0,p)} \leq z \right),
\]

where \( z = n \) and \( \varepsilon = \sqrt{\log(qn)} \). By Assumption (E) and exponential inequality, we have that \( L_{z,\varepsilon} \leq C \sqrt{\log(qn)} \) holds with probability \( 1 - C_1 n^{-1} \).
where \( z > 0 \) and \( \varepsilon = O(s_0 \log^2(qn)n^{-1/2}) \). Let \( \mathcal{E}^{R,q} = \{ \mathbf{x} \in \mathbb{R}^q : \| \mathbf{x} \| \leq R \} \)
and \( V^{z,q}_{(s_0,p)} = \{ \mathbf{x} \in \mathbb{R}^q : \| \mathbf{x} \|_{(s_0,p)} \leq z \} \). We then have
\[
L_{z,\varepsilon} \leq \mathbb{P}(G \in \mathbb{R}^q \setminus \mathcal{E}^{R,q}) + \mathbb{P}(G \in V^{z+\varepsilon,q}_{(s_0,p)} \cap \mathcal{E}^{R,q}) - \mathbb{P}(G \in V^{z,q}_{(s_0,p)} \cap \mathcal{E}^{R,q}).
\]

By the tail probability of Gaussian distribution, we have
\[
L_1 \leq q(2\pi R^2 q^{-1})^{-1/2} \exp(-R^2 q^{-1}/2).
\]

For \( L_2 \), by Lemma A.3, there is a \( m \)-generated convex set \( A^m \subset \mathbb{R}^q \)
such that
\[
A^m \subset V^{z,q}_{(s_0,p)} \cap \mathcal{E}^{R,q} \subset A^{m,R\varepsilon} \text{ and } m \leq q s_0 \left( \frac{5}{\sqrt{\varepsilon}} \ln \frac{1}{\varepsilon} \right)^{5/2}.
\]

Hence, there is a constant \( C \) such that
\[
V^{z+\varepsilon}_{(s_0,p)} \cap \mathcal{E}^{R,q} \subset A^{m,R\varepsilon+C\varepsilon}
\]

By setting \( R = qn \) and \( \varepsilon = (qn)^{-2} \), we have \( R\varepsilon \lesssim \varepsilon \) and \( L_1 = o(1) \). By Lemma A.4, we combine (C.9) and (C.10) to obtain \( L_2 \leq C \varepsilon s_0 \sqrt{\log(qn)} = O(s_0^2 \log^{5/2}(qn)n^{-1/2}) \).

By Assumption (A), we have \( L_2 = o(1) \), which finishes the proof.

**C.3. Proof of Lemma B.3.**

**Proof.** In Lemma B.3, we aim to bound \( \hat{D}_5 \), where
\[
\hat{D}_5 := \sup_{z>0} \left| \mathbb{P}(\| \mathbf{G}^N \|_{(s_0,p)} > z) - \mathbb{P}(\| \mathbf{N}^b \|_{(s_0,p)} > z|\mathcal{X},\mathcal{Y}) \right|.
\]

To bound \( \hat{D}_5 \), we need to analyze the distributions of \( \mathbf{G}^N \) and \( \mathbf{N}^b|\mathcal{X},\mathcal{Y} \). Considering the definitions of \( \mathbf{\Sigma}_\gamma \) and \( \mathbf{\hat{\Sigma}}_\gamma \) in (3.4) and (3.9), by setting
\[
\mathbf{\Sigma}_{12} = \mathbf{\Sigma}_1/n_1 + \mathbf{\Sigma}_2/n_2 \text{ and } \mathbf{\hat{\Sigma}}_{12} = \mathbf{\hat{\Sigma}}_1/n_1 + \mathbf{\hat{\Sigma}}_2/n_2,
\]
we have \( \mathbf{G}^N \sim \mathcal{N}(\mathbf{0}, \mathbf{R}_{12}) \) and \( \mathbf{N}^b|\mathcal{X},\mathcal{Y} \sim \mathcal{N}(\mathbf{0}, \mathbf{\hat{R}}_{12}) \), where \( \mathbf{R}_{12} \) and \( \mathbf{\hat{R}}_{12} \)
are defined as
\[
\mathbf{R}_{12} = \text{Diag}(\mathbf{\Sigma}_{12})^{-1/2} \mathbf{\Sigma}_{12} \text{Diag}(\mathbf{\Sigma}_{12})^{-1/2} = (r_{12,ij})_{1 \leq i,j \leq q}, \quad \mathbf{\hat{R}}_{12} = \text{Diag}(\mathbf{\hat{\Sigma}}_{12})^{-1/2} \mathbf{\hat{\Sigma}}_{12} \text{Diag}(\mathbf{\hat{\Sigma}}_{12})^{-1/2} = (\hat{r}_{12,ij})_{1 \leq i,j \leq q}.
\]

**Lemma C.2.**
After analyzing the distributions of $G^N$ and $N^b|\mathcal{X}, \mathcal{Y}$, we then bound $\hat{D}_5$. For this, we rewrite $\hat{D}_5$ as $\hat{D}_5 = \max \left( \sup_{z \in (0, \tilde{R})} I_z, \sup_{z \in (\tilde{R}, \infty)} I_z \right)$, where

$$I_z = |\mathbb{P}(\|G^N\|_{(s_0,p)} > z) - \mathbb{P}(\|N^b\|_{(s_0,p)} > z|\mathcal{X}, \mathcal{Y})|,$$

and $\tilde{R} = C s_0 \sqrt{n}$. For $\sup_{z \in (\tilde{R}, \infty)} I_z$, considering $\|v\|_{(s_0,p)} \leq s_0^{1/p} \|v\|_\infty \leq s_0 \|v\|_\infty$, we have

$$\sup_{z \in (\tilde{R}, \infty)} I_z \leq \mathbb{P}(\|G^N\|_\infty > C \sqrt{n}) + \mathbb{P}(\|N^b\|_\infty > C \sqrt{n}|\mathcal{X}, \mathcal{Y}).$$

Considering $r_{12, ii} = \tilde{r}_{12, ii} = 1$, by the tail probability of Gaussian distribution, we further have

$$\sup_{z \in (\tilde{R}, \infty)} I_z \leq C q \exp(-C_1 n) = o(1).$$

We now bound $\sup_{z \in (0, \tilde{R})} I_z^D$. Let $\mathcal{E}_{\tilde{R}, q} = \{x \in \mathbb{R}^q : \|x\| \leq \tilde{R}\}$ and $V_{(s_0,p)}^{z,q} = \{x \in \mathbb{R}^q : \|x\|_{(s_0,p)} \leq z\}$. Hence, considering $\|x\| \leq q^{1/2} \|x\|_\infty \leq q^{1/2} \|x\|_{(s_0,p)}$, we have $V_{(s_0,p)}^{z,q} \subset \mathcal{E}_{\tilde{R}, q}^{1/2,q}$ for $z < \tilde{R}$. Therefore, Considering Lemma A.3, there is a $m$-generated convex set $A^m$ and $\epsilon > 0$ such that

$$A^m \subset V_{(s_0,p)}^{z,d} \subset A^m_{\tilde{R} q^{1/2} \epsilon} \quad \text{and} \quad m \leq d_0 \left( \frac{\gamma}{\sqrt{\epsilon}} \ln \frac{1}{\epsilon} \right)^{s_0^2}.$$

Let $\epsilon' = R q^{1/2} \epsilon$. By setting $\epsilon = (qn)^{-3/2}$, we have $\epsilon' = s_0(qn)^{-1}$. We then have $I_z \leq L_{z,1} + L_{z,2}$ with

$$L_{z,1} = \max \left( \mathbb{P}(G^N \in A^{m,\epsilon'} \setminus A^m), \mathbb{P}(N^b \in A^{m,\epsilon'} \setminus A^m) \right)$$

and

$$L_{z,2} = \max \left( \mathbb{P}(G^N \in A^{m,\epsilon'} \setminus A^m) - \mathbb{P}(N^b \in A^{m,\epsilon'}|\mathcal{X}, \mathcal{Y}), \right.$$

$$\left. \mathbb{P}(G^N \in A^m) - \mathbb{P}(N^b \in A^m|\mathcal{X}, \mathcal{Y}) \right),$$

for $z < \tilde{R}$. We then separately bound $L_{z,1}$ and $L_{z,2}$. For $L_{z,1}$, by Lemma A.4 and Assumption (A), we have

$$L_{z,1} \leq C \epsilon' \sqrt{\log(m)} = C s_0^2(qn)^{-1} \sqrt{\log(qn)} = o(1).$$

Considering $V_{s_0} := \{v \in \mathbb{S}^{q-1} : \|v\|_0 \leq s_0\}$, we have

$$\sup_{v_1, v_2 \in V_{s_0}} |v_1^T (\hat{R}_{12} - R_{12}) v_2| \leq \|\hat{R}_{12} - R_{12}\|_\infty \|v_1\|_1 \|v_2\|_1$$

$$\leq s_0 \|\hat{R}_{12} - R_{12}\|_\infty.$$
Therefore, combining Theorem 4.1 and Remark 4.1 in [7], by Lemma C.2, with probability at least $1 - C_1 n^{-1}$, we have

$$L_{z,2} \leq C \left( s_0 \frac{\log^{3/2}(qn)}{\sqrt{n}} \right)^{1/3} \log^{2/3}(mn) \leq C \left( \frac{s_0^{10} \log^7(qn)}{n} \right)^{1/6}. \tag{C.16}$$

From Assumption (A), we have $L_{z,2} = o(1)$, which finishes the proof. \qed

C.4. Proof of Lemma B.4.

PROOF. We first prove for $m > 1$. By the definition of $N_s^1$ in (B.28), we have

$$N_s^1 = \frac{\hat{u}_{1,s} - \hat{u}_{2,s} - u_{1,s} + u_{2,s}}{\sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2}}, \quad \frac{\sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2}}{\sqrt{\bar{v}_{1,s}/n_1 + \bar{v}_{2,s}/n_2}}. \tag{C.17}$$

By Lemma A.6 and Lemma C.1, for sufficiently large $n$ with probability at least $1 - C_1 n^{-1}$ we have

$$1 - \sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2} \left| 1 - \frac{\bar{v}_{1,s}/n_1 + \bar{v}_{2,s}/n_2}{\sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2}} \right| \leq C \log^{3/2}(qn) \sqrt{n}. \tag{C.18}$$

By setting

$$\mathcal{E}(z) = \left\{ \left| 1 - (\bar{v}_{1,s}/n_1 + \bar{v}_{2,s}/n_2)^{-1/2} (m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2)^{1/2} \right| \leq z \right\}$$

and $z \asymp \log^{3/2}(qn)/\sqrt{n}$, we can bound $\mathbb{P}(|N_s^1| \geq x)$ by

$$\mathbb{P}(|N_s^1| \geq x) \leq \mathbb{P}(|N_s^1| \geq x, \mathcal{E}(z)) + Cn^{-1}. \tag{C.19}$$

By the definition of $\mathcal{E}(z)$ and (C.17), we then have

$$\mathbb{P}(|N_s^1| \geq x, \mathcal{E}(z)) \leq \mathbb{P} \left( \left| \frac{\hat{u}_{1,s} - \hat{u}_{2,s} - u_{1,s} + u_{2,s}}{\sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2}} \right| \geq (1 + z)^{-1}x \right)$$

Considering $z = o(1)$ and $x = u\sqrt{2\log q}$ in Lemma B.4, to prove (B.38), we only need to prove that as $n, q \to \infty$, we have

$$s_0 \mathbb{P} \left( \left| \frac{\hat{u}_{1,s} - \hat{u}_{2,s} - u_{1,s} + u_{2,s}}{\sqrt{m^2 \sigma_{1,ss}/n_1 + m^2 \sigma_{2,ss}/n_2}} \right| \geq C \sqrt{\log q} \right) \to 0,$$

\text{as } A_1
uniformly for \( s \). By triangle and Hoeffding’s inequalities, we have
\[
 s_0 A_1 \leq s_0 \mathbb{P} \left( \left| \frac{1}{n_1} \sum_{k=1}^{n_1} h_s(X_k) - \frac{1}{n_2} \sum_{k=1}^{n_2} h_s(Y_k) \right| \geq \frac{C}{2} \sqrt{\log q} \right)
\]
\[+ s_0 \mathbb{P} \left( \left| \frac{(n_1)^{-1} \Delta_{n_1, s} - (n_2)^{-1} \Delta_{n_2, s}}{\sqrt{m^2 \sigma_{1, ss}/n_1 + m^2 \sigma_{2, ss}/n_2}} \right| \geq \frac{C}{2} \sqrt{\log q} \right).
\]

By the exponential inequality for sub-exponential distribution, considering Assumption (A)’ we have \( s_0 A_2 \leq s_0 \exp(-C \log^{1/2}(q)) \to 0 \). As \( A_3 \) does not exist for \( m = 1 \), we only need to deal with \( m > 1 \). Similarly to (C.3), we threshold the kernel of \( \hat{u}_{\gamma, s} - u_{\gamma, s} \) by \( B_n = C \log(q) \) and construct the threshold residual \( \hat{\Delta}_{n_{\gamma, s}} \). Similarly to the proof of bounding \( (n_1)^{-1} \Delta_{n_1, s} - (n_2)^{-1} \Delta_{n_2, s} \) in Lemma B.1, by setting
\[
 A_{3,1} = \mathbb{P} \left( \left| \left( \frac{n_1}{m} \right)^{-1} \hat{\Delta}_{n_1, s} - \left( \frac{n_2}{m} \right)^{-1} \hat{\Delta}_{n_2, s} \right| > \frac{C}{n} \sqrt{\log q} \right)
\]
\[A_{3,2} = \max_{i,j} \left( \mathbb{P}(|\Psi_s(X_{i_1}, \ldots, X_{i_m})| > B_n) + \mathbb{P}(|\Psi_s(Y_{j_1}, \ldots, Y_{j_m})| > B_n) \right).
\]

For proving \( s_0 A_3 \to 0 \), we only need to prove \( s_0 A_{3,1} \to 0, s_0 n^m A_{3,2} \to 0 \), and \(|E_{1, s}| + |E_{2, s}| \prec \log q/n\), where \( E_{\gamma, s} \) is defined in (C.3). By by Proposition 2.3 (c) in [1], under Assumption (A)’, we have
\[
 s_0 A_{3,1} \leq C_1 s_0 \exp \left( - \left( m \log^{-\frac{1}{2}}(q) \right)^{\frac{1}{m}} \right) \to 0.
\]

As \( \Psi_s(X_{i_1}, \ldots, X_{i_m}) \) and \( \Psi_s(X_{i_1}, \ldots, X_{i_m}) \) have sub-exponential tails from Assumption (E), similarly to the proof in Lemma B.1, under Assumption (A)’ we have \( s_0 n^m A_{3,2} \to 0 \), and \(|E_{1, s}| + |E_{2, s}| \prec \log q/n\), which finishes the proof.

\[\square\]

**C.5. Proof of Lemma B.5.**

**Proof.** In Lemma B.5, we aim to prove (B.41). For this, we need to bound
\[
 \sup_{z \in [\epsilon, 1-\epsilon]} \left| 1 - \tilde{\mathbb{F}}_{N, \text{ad}}(z) - \mathbb{P}(N_{\text{ad}} > z | \mathcal{X}, \mathcal{Y}) \right|
\]

By the definition of \( N_{\text{ad}} \) in (3.16), we have \( N_{\text{ad}} = \min_{p \in \mathcal{P}} \hat{P}_{(s_0, p)}^N \), where \( \mathcal{P} \) is a finite set. Therefore, without loss of generality, we assume \( \mathcal{P} = \{p_1, p_2\} \).
with $1 \leq p_1 \neq p_2 \leq \infty$. We then have $N_{ad} = \min\left(\hat{P}_{(s_0,p_1)}^N, \hat{P}_{(s_0,p_2)}^N\right)$. We then have $\mathbb{P}(N_{ad} > z|\mathcal{X}, \mathcal{Y}) = \mathbb{P}\left(\left\{\hat{P}_{(s_0,p_1)}^N > z\right\} \cap \left\{\hat{P}_{(s_0,p_2)}^N > z\right\}\right)\mathcal{X}, \mathcal{Y}$. In (B.19) and (B.21), we introduce $F_{N^b,(s_0,p_1)}(z)$ and $\tilde{F}_{N^b,(s_0,p_1)}(z)$ as

\begin{equation}
F_{N^b,(s_0,p_1)}(z) = \mathbb{P}(\|N^b\|_{(s_0,p_1)} \leq z|\mathcal{X}, \mathcal{Y}),
\end{equation}

\begin{equation}
\tilde{F}_{N^b,(s_0,p_1)}(z) = \frac{\sum_{b=1}^{B} 1_{\{\|N^b\|_{(s_0,p_1)} \leq z\}} + 1}{B + 1},
\end{equation}

for $\ell = 1, 2$. By the definition of $\hat{P}_{(s_0,p_1)}^N$ in (2.8), we then have $\hat{P}_{(s_0,p_1)}^N = 1 - \tilde{F}_{N^b,(s_0,p_1)}(N_{(s_0,p_1)})$. Therefore, we can rewrite $\mathbb{P}(N_{ad} > z|\mathcal{X}, \mathcal{Y})$ as

\begin{equation}
\mathbb{P}\left(\tilde{F}_{N^b,(s_0,p_1)}(N_{(s_0,p_1)}) < 1 - z, \tilde{F}_{N^b,(s_0,p_2)}(N_{(s_0,p_2)}) < 1 - z|\mathcal{X}, \mathcal{Y}\right).
\end{equation}

Similarly, by setting $F_{N,(s_0,p_1)}(z) = \mathbb{P}(N_{(s_0,p_1)} \leq z)$ we can also rewrite

\begin{equation}
\mathbb{P}\left(F_{N,(s_0,p_1)}(N_{(s_0,p_1)}) < 1 - z, F_{N,(s_0,p_2)}(N_{(s_0,p_2)}) < 1 - z\right).
\end{equation}

Combining (C.21) and (C.22), by setting

\begin{align*}
D_1(z) &= \mathbb{P}\left(F_{N,(s_0,p_1)}(N_{(s_0,p_1)}) < 1 - z, F_{N,(s_0,p_2)}(N_{(s_0,p_2)}) < 1 - z\right),

D_2(z) &= \mathbb{P}\left(\tilde{F}_{N^b,(s_0,p_1)}(N_{(s_0,p_1)}) < 1 - z, \tilde{F}_{N^b,(s_0,p_2)}(N_{(s_0,p_2)}) < 1 - z\right),
\end{align*}

we have $\left|1 - \mathbb{F}_{N_{ad}}(z) - \mathbb{P}(N_{ad} > z|\mathcal{X}, \mathcal{Y})\right| = \left|D_1(z) - D_2(z)\right|$. By Glivenko-Cantelli Theorem, we have $\lim_{B \to \infty} \sup_{z \in \mathbb{R}} \left|\tilde{F}_{N^b,(s_0,p_1)}(z) - F_{N^b,(s_0,p_1)}(z)\right| = 0$ almost surely, which motivates us to introduce

\begin{equation}
D_3(z) = \mathbb{P}\left(F_{N^b,(s_0,p_1)}(N_{(s_0,p_1)}) < 1 - z, F_{N^b,(s_0,p_2)}(N_{(s_0,p_2)}) < 1 - z\right).
\end{equation}

We then use the triangle inequality to bound $\left|1 - \mathbb{F}_{N_{ad}}(z) - \mathbb{P}(N_{ad} > z|\mathcal{X}, \mathcal{Y})\right|$ by

\begin{equation}
\left|1 - \mathbb{F}_{N_{ad}}(z) - \mathbb{P}(N_{ad} > z|\mathcal{X}, \mathcal{Y})\right| \leq \left|D_1(z) - D_3(z)\right| + \left|D_3(z) - D_2(z)\right|.
\end{equation}

By (C.23), to prove (B.41), it is sufficient to prove that as $n, B \to \infty$, we have

\begin{equation}
\sup_{z \in [\epsilon, 1 - \epsilon]} |D_1(z) - D_3(z)| \to 0 \quad \text{and} \quad \sup_{z \in [\epsilon, 1 - \epsilon]} |D_3(z) - D_2(z)| \to 0,
\end{equation}
for any fixed $\epsilon > 0$.

By Lemma 5 in [3], we can prove

\[(C.25) \quad \lim_{B \to \infty} \sup_{z \in [\epsilon, 1-\epsilon]} |D_3(z) - D_2(z)| = 0.\]

Hence, we only need to prove $\lim_{n \to \infty} \sup_{z \in [\epsilon, 1-\epsilon]} |D_1(z) - D_3(z)| = 0$. For this, we introduce the following lemma.

**Lemma C.3.** Assumptions (A)', (E), (M1), and (M2) hold. Under $H_0$ of (1.8) for any $\epsilon > 0$ we have

\[\sup_{z \in [\epsilon, 1-\epsilon]} |D_1(z) - D_3(z)| \to 0, \quad \text{as } n \to \infty.\]

The proof of Lemma C.3 is in Appendix D.2 of supplementary materials. Combining (C.25) and Lemma C.3, we prove (C.24), which finishes the proof of Lemma B.5.

**C.6. Proof of Lemma B.6.**

**Proof.** In Lemma B.6, we aim to prove (B.52). We set

\[F_{N, \text{ad}}(z) = \mathbb{P}(N_{\text{ad}} \leq z|X, Y) \quad \text{and} \quad F_{N^b, \text{ad}}(z) = \mathbb{P}(N_{\text{ad}}^b \leq z|X, Y),\]

where $N_{\text{ad}}$ and $N_{\text{ad}}^b$ are defined in (2.10) and (B.48). Hence, to prove (B.52), it is sufficient to prove

\[(C.26) \quad \sup_{z \in [\epsilon, 1-\epsilon]} \left| \mathbb{P}(N_{\text{ad}} > z|X, Y) - \mathbb{P}(N_{\text{ad}}^b > z|X, Y) \right| \to 0 \quad \text{as } n, B \to \infty.\]

Without loss of generality, we assume $\mathcal{P} = \{p_1, p_2\}$ with $1 \leq p_1 \neq p_2 \leq \infty$. We can then rewrite $\mathbb{P}(N_{\text{ad}} > z|X, Y)$ as

\[(C.27) \quad \mathbb{P}\left(\hat{F}_{N^b, (s_0, p_1)}(N_{(s_0, p_1)}) < 1 - z, \hat{F}_{N^b, (s_0, p_2)}(N_{(s_0, p_2)}) < 1 - z|X, Y\right),\]

where $\hat{F}_{N^b, (s_0, p_\ell)}(z)$ is defined in (C.20). Similarly, we can rewrite $\mathbb{P}(N_{\text{ad}}^b > z|X, Y)$

\[(C.28) \quad \mathbb{P}\left(F_{N^b, (s_0, p_1)}(N_{(s_0, p_1)}) < 1 - z, F_{N^b, (s_0, p_2)}(N_{(s_0, p_2)}) < 1 - z|X, Y\right),\]

where $F_{N^b, (s_0, p_\ell)}(z)$ is defined in (B.48). Let

\[L = \mathbb{P}\left(F_{N^b, (s_0, p_1)}(N_{(s_0, p_1)}) < 1 - z, F_{N^b, (s_0, p_2)}(N_{(s_0, p_2)}) < 1 - z|X, Y\right).\]
By Massart’s inequality (see Section 1.5 in [10]) and Lemma 5 in [11], under Assumptions (A)′′, (E), (M1), and (M2), for any fix \( \epsilon > 0 \), we have

\[
(C.29) \quad \sup_{z \in [\epsilon, 1-\epsilon]} \left| \mathbb{P}(N_{\text{ad}} > z | \mathcal{X}, \mathcal{Y}) - L \right| \to 0 \quad \text{as} \quad n, B \to \infty.
\]

Similarly to the proof of Theorems 3.1, considering (C.28), we also have

\[
(C.30) \quad \sup_{z \in [0,1]} \left| \mathbb{P}(N_{\text{ad}} > z | \mathcal{X}, \mathcal{Y}) - L \right| \to 0, \quad \text{as} \quad n, B \to \infty.
\]

Combining (C.29) and (C.30), we use the triangle inequality to obtain (C.26), which finishes the proof of Lemma B.6.

\[\square\]

C.7. Proof of Lemma B.7.

**Proof.** In Lemma B.7, we aim to prove (B.53). By the definitions of \( F_{N^b, \text{ad}}(z) \) and \( \hat{F}_{N, \text{ad}'}(z) \) in (B.49) and (B.50), we have

\[
1 - F_{N^b, \text{ad}}(z) = \mathbb{P}(N_{\text{ad}}^b > z | \mathcal{X}, \mathcal{Y})
\]

\[
(C.31) \quad 1 - \hat{F}_{N, \text{ad}'}(z) = \sum_{b=1}^{B} \mathbb{I}\{N_{\text{ad}}^b > z | \mathcal{X}, \mathcal{Y}\} / (B + 1),
\]

where \( N_{\text{ad}}^b \) and \( N_{\text{ad}}^b \) are defined in (B.48) and (2.12). Therefore, for (B.53) it is sufficient to prove

\[
(C.32) \quad \sup_{z \in [\epsilon, 1-\epsilon]} \left| \mathbb{P}(N_{\text{ad}}^b > z | \mathcal{X}, \mathcal{Y}) - \left(1 - \hat{F}_{N, \text{ad}'}(z)\right) \right| \to 0,
\]

as \( n, B \to \infty \). Without loss of generality, we assume \( \mathcal{P} = \{p_1, p_2\} \) with \( 1 \leq p_1 \neq p_2 \leq \infty \), which yields

\[
(C.33) \quad N_{\text{ad}}^b = \min \left( \hat{P}_{(s_0,p_1)}^{b,N}, \hat{P}_{(s_0,p_2)}^{b,N} \right),
\]

where \( \hat{P}_{(s_0,p)}^{b,N} \) is defined in (2.12). Combining (C.31) and (C.33), we then have

\[
(C.34) \quad 1 - \hat{F}_{N, \text{ad}'}(z) = \frac{\sum_{b=1}^{B} \mathbb{I}\{\hat{P}_{(s_0,p_1)}^{b,N} > z, \hat{P}_{(s_0,p_2)}^{b,N} > z | \mathcal{X}, \mathcal{Y}\}}{B + 1}.
\]
By setting $\hat{F}^{b,N}_{(s_0,p)}(z) = B^{-1} \left( \sum_{b_1 \neq b} \mathbb{I}\{N_{(s_0,p)}^{b_1} \leq z|\mathcal{X},\mathcal{Y} \} + 1 \right)$, considering the definition of $\hat{F}^{b,N}_{(s_0,p)}$ in (2.12), we have $\hat{P}^{b,N}_{(s_0,p)} = 1 - \hat{F}^{b,N}_{(s_0,p)}(N^{b}_{(s_0,p)})$. Therefore, by (C.34), we rewrite $1 - \hat{F}^{N,ad'}_{(s_0,p)}(z)$ as

$$\sum_{b=1}^{B} \mathbb{I}\left\{ \hat{F}^{b,N}_{(s_0,p_1)}(N^{b}_{(s_0,p_1)}) < 1 - z, \hat{F}^{b,N}_{(s_0,p_2)}(N^{b}_{(s_0,p_2)}) < 1 - z|\mathcal{X},\mathcal{Y} \right\} \over B + 1,$$

As $\hat{F}^{b,N}_{(s_0,p)}(z) \to F_{N^b,(s_0,p)}(z)$, to approximate $1 - \hat{F}^{N,ad'}_{(s_0,p)}(z)$ we introduce $S(z)$ as

$$\sum_{b=1}^{B} \mathbb{I}\left\{ F_{N^b,(s_0,p_1)}(N^{b}_{(s_0,p_1)}) < 1 - z, F_{N^b,(s_0,p_2)}(N^{b}_{(s_0,p_2)}) < 1 - z|\mathcal{X},\mathcal{Y} \right\} \over B + 1,$$

where $F_{N^b,(s_0,p_2)}$ is defined in (B.48). To analyze the difference between $1 - \hat{F}^{N,ad'}_{(s_0,p)}(z)$ and $S(z)$, we introduce the following lemma.

**Lemma C.4.** Let $\epsilon$ be any positive real number, we have

$$\sup_{z \in [\epsilon, 1-\epsilon]} |1 - \hat{F}^{N,ad'}_{(s_0,p)}(z) - S(z)| = 0, \text{ as } n, B \to \infty.$$  

The proof of Lemma C.4 is in Appendix D.3. Considering $N_{ad}^b = \min_{p \in \mathcal{P}} \left( 1 - F_{N^b,(s_0,p)}(N^{b}_{(s_0,p)}) \right)$ from (B.48), we can rewrite $S(z)$ as

$$S(z) = (B + 1)^{-1} \sum_{b=1}^{B} \mathbb{I}\{N_{ad}^b > z|\mathcal{X},\mathcal{Y} \}.$$  

By Massart’s inequality (see Section 1.5 in [10]), we have

$$\sup_{z \in [0,1]} |S(z) - \mathbb{P}(N_{ad}^b > z|\mathcal{X},\mathcal{Y})| \to 0,$$

as $n, B \to \infty$. Combining Lemma C.4 and (C.37), we plug in $S(z)$ and use the triangle inequality to obtain (C.32), which finishes the proof of Lemma B.7.

**APPENDIX D: PROOFS OF LEMMAS IN APPENDIX C**

**D.1. Proof of Lemma C.1.**
which implies (C.8). Hence, we finish the proof of Lemma C.1.

For any \(s \in \{1, \ldots, q\}\). Considering \(y \in (0, 1]\), by the simple calculation, \(|1 - \xi_s| \leq y/2\) implies
\[
|1 - \xi_s^{-1}| \leq \max \left(\frac{y}{2 + y}, \frac{y}{2 - y}\right) \leq y,
\]
for any \(s \in \{1, \ldots, q\}\). Therefore, we have
\[
\left\{ \max_{1 \leq s \leq q} |1 - \xi_s| \leq y/2 \right\} \subseteq \left\{ \max_{1 \leq s \leq q} |1 - \xi_s^{-1}| \leq y \right\},
\]
which implies (C.8). Hence, we finish the proof of Lemma C.1. \(\square\)

D.2. Proof of Lemma C.3.

Proof. Without loss of generality, we assume \(P = \{p_1, p_2\}\) with \(1 \leq p_1 < p_2 \leq \infty\). We set
\[
\begin{align*}
D_1(z) = & \mathbb{P}\left(F_{N,(s_0,p_1)}\left(N(s_0,p_1)\right) < 1 - z, F_{N,(s_0,p_2)}\left(N(s_0,p_2)\right) < 1 - z\right), \\
D_3(z) = & \mathbb{P}\left(F_{N^b,(s_0,p_2)}\left(N(s_0,p_2)\right) < 1 - z, F_{N^b,(s_0,p_2)}\left(N(s_0,p_2)\right) < 1 - z\right),
\end{align*}
\]
where \(F_{N,(s_0,p_2)}(z)\) and \(F_{N^b,(s_0,p_2)}(z)\) are defined in (B.19) and (B.21). In Lemma C.3, we aim to prove
\[
\lim_{n \to \infty} \sup_{z \in [1 - \epsilon]} |D_1(z) - D_3(z)| = 0.
\]
By following the proof of Theorem 3.1, under Assumptions (A)”’, (E), (M1), and (M2), by setting
\[
\begin{align*}
F_{N,12}(z_1, z_2) = & \mathbb{P}\left(N(s_0,p_1) \leq z_1, N(s_0,p_2) \leq z_2\right), \\
F_{G,12}(z_1, z_2) = & \mathbb{P}\left(\|G^N\|_{(s_0,p_1)} \leq z_1, \|G^N\|_{(s_0,p_2)} \leq z_2\right),
\end{align*}
\]
with \(G^N \sim N(0,R_{12})\) with \(R_{12}\) defined in (B.9), we have
\[
\sup_{z_1, z_2 \in (0, \infty)} \left|F_{N,12}(z_1, z_2) - F_{G,12}(z_1, z_2)\right| \to 0, \quad \text{as } n \to \infty.
\]
(D.3) motives us to introduce
\[
\begin{align*}
D_4(z) = & \mathbb{P}\left(F_{N,(s_0,p_1)}\left(\|G^N\|_{(s_0,p_1)}\right) < 1 - z, F_{N,(s_0,p_2)}\left(\|G^N\|_{(s_0,p_2)}\right) < 1 - z\right), \\
D_5(z) = & \mathbb{P}\left(F_{N^b,(s_0,p_1)}\left(\|G^N\|_{(s_0,p_1)}\right) < 1 - z, F_{N^b,(s_0,p_2)}\left(\|G^N\|_{(s_0,p_2)}\right) < 1 - z\right).
\end{align*}
\]
Combining (D.1) and (D.3), we then have
\[ \sup_{z \in (0,1)} |D_1(z) - D_4(z)| \to 0 \quad \text{and} \quad \sup_{z \in (0,1)} |D_3(z) - D_5(z)| \to 0, \]
as \( n \to \infty \). Therefore, by using the triangle inequality, to prove (D.2) we only need to prove
\[ (D.4) \sup_{z \in [\epsilon, 1-\epsilon]} |D_4(z) - D_5(z)| \to 0, \quad \text{as} \quad n \to \infty. \]

By Assumption (A)$''$, considering Theorems 3.1, for any \( \epsilon > 0 \) and sufficiently large \( n \), we have
\[ \sup_{z \in [\epsilon, 1-\epsilon]} \left| F_{N,(s_0,p)}(z) - F_{N,(s_0,p)}(0) \right| \leq h_{q,N}(\epsilon) \sup_{t \in \mathbb{R}} \left| F_{N,(s_0,p)}(t) - F_{N,(s_0,p)}(0) \right|. \]
Moreover, by the proof of Lemma B.2 we have
\[ \sup_{z \in [\epsilon, 1-\epsilon]} |D_4(z) - D_5(z)| \leq C h_{q,N}(\epsilon) s_0 \sqrt{\log(nq)} \sup_{t \in \mathbb{R}} \left| F_{N,(s_0,p)}(t) - F_{N,(s_0,p)}(0) \right|, \]
for sufficiently large \( n \). By the proof of Lemma A.1, B.2, B.3 and Theorem 3.1, under Assumption (A)$''$, (E), (M1), and (M2), we have
\[ \sup_{z \in [\epsilon, 1-\epsilon]} |D_4(z) - D_5(z)| \leq C h_{q,N}(\epsilon) s_0 \sqrt{\log(nq)} \left( \frac{14 \log^7(qn)}{n} \right)^{1/6}. \]
In Assumption (A)$''$, we set \( h_{q,N}(\epsilon) s_0^2 \log(nq) = o(n^{1/10}) \). Therefore, we have
\[ \sup_{z \in [\epsilon, 1-\epsilon]} |D_4(z) - D_5(z)| \to 0, \quad \text{as} \quad n \to \infty, \]
which finishes the proof.

\[ \square \]

**D.3. Proof of Lemma C.4.**

**Proof.** In Lemma C.4, we aim to prove \( \sup_{z \in [\epsilon, 1-\epsilon]} |1 - \widehat{F}_{N,ad'}(z) - S(z)| \to 0 \), as \( n, B \to \infty \). For this, we need to prove that for any \( \delta, \tilde{\epsilon} > 0 \)
\[ (D.5) \quad \mathbb{P} \left( \sup_{z \in [\epsilon, 1-\epsilon]} |1 - \widehat{F}_{N,ad'}(z) - S(z)| > \delta \right) < \tilde{\epsilon}, \]
holds for sufficient large \( n \) and \( B \). By setting
\[
\hat{F}_{(s_0,p)}^{b,N}(z) = B^{-1}\left(\sum_{b_1 \neq b} \mathbb{I}\{N_{(s_0,p)}^{b_1} \leq z\{X, Y\} + 1\}\right),
\]
considering Massart’s inequality (Section 1.5 in [10]), we have
\[
\sup_{1 \leq b \leq B} \sup_{z \in \mathbb{R}} \left| \hat{F}_{(s_0,p)}^{b,N}(z) - F_{N_{(s_0,p)}^{b}}(z) \right| \to 0, \quad \text{as } n, B \to \infty.
\]
Considering Lemma 5 in [3], for any fixed \( \epsilon, \delta > 0 \), by setting
\[
\mathcal{A}(\delta') = \left\{ \sup_{1 \leq b \leq B} \sup_{z \in [\epsilon, 1-\epsilon]} \left| \hat{F}_{(s_0,p)}^{b,N}(z) - F_{N_{(s_0,p)}^{b}}(z) \right| \leq \delta' \right\},
\]
as \( n \) and \( B \) are sufficiently large, we have \( \mathbb{P}(\mathcal{A}(\delta')) \leq \bar{\varepsilon}/2 \). Therefore, considering that \( F_{N_{(s_0,p)}^{b}}(z) \) is Lipschitz continuous on \( z \in [\epsilon, 1-\epsilon] \), by the definitions of \( 1 - \hat{F}_{N_{(s_0,p)}^{ad}} \) and \( S(z) \) in (C.35) and (C.36), under \( \mathcal{A}(\delta') \) there is a constant \( C \) such that \( S(z + C\delta') \leq 1 - \hat{F}_{N_{(s_0,p)}^{ad}}(z) \leq S(z - C\delta') \) holds for any \( z \in [\epsilon, 1-\epsilon] \) and sufficiently large \( n \) and \( B \). Hence, under \( \mathcal{A}(\delta') \) we have \( \sup_{z \in [\epsilon, 1-\epsilon]} \left| 1 - \hat{F}_{N_{(s_0,p)}^{ad}}(z) - S(z) \right| \leq \mathcal{L} \) with
\[
\begin{align*}
\mathcal{L} &= \max \left( \sup_{z \in [\epsilon, 1-\epsilon]} \left| S(z + C\delta') - S(z) \right|, \sup_{z \in [\epsilon, 1-\epsilon]} \left| S(z - C\delta') - S(z) \right| \right).
\end{align*}
\]
Therefore, to prove (D.5), we only need to prove
\[
\mathbb{P}\left( \mathcal{L} > \delta, \mathcal{A}(\delta') \right) \leq \bar{\varepsilon}/2,
\]
for sufficiently large \( n \) and \( B \). By Massart’s inequality (Section 1.5 in [10]) and the definition of \( S(z) \) in (C.36), we have
\[
\sup_{z \in [0, 1]} \left| S(z) - F_{N_{(s_0,p)}^{ad}}(z) \right| \to 0, \quad \text{as } n, B \to \infty,
\]
where \( F_{N_{(s_0,p)}^{ad}}(z) \) is defined in (B.49). By (D.8), the limit of \( \mathcal{L} \) is
\[
\max \left( \sup_{z \in [\epsilon, 1-\epsilon]} \left| F_{N_{(s_0,p)}^{ad}}(z + C\delta') - F_{N_{(s_0,p)}^{ad}}(z) \right|, \sup_{z \in [\epsilon, 1-\epsilon]} \left| F_{N_{(s_0,p)}^{ad}}(z - C\delta') - F_{N_{(s_0,p)}^{ad}}(z) \right| \right).
\]
As \( F_{N_{(s_0,p)}^{ad}}(z) \) is uniformly Lipschitz contentious on \( [\epsilon, 1-\epsilon] \), there is a constant \( C_1 \) such that
\[
0 \leq \mathcal{L} \leq C_1 \delta',
\]
holds for sufficiently large \( n \) and \( B \). By setting \( \delta' \) small enough and (D.9), we obtain (D.7), which finishes the proof of Lemma C.4. \[\square\]
APPENDIX E: PROOF OF USEFUL LEMMAS IN APPENDIX A

E.1. Proof of Lemma A.1. By setting $E^{R,d} = \{x \in \mathbb{R}^d : \|x\| \leq R\}$, from Assumption (E)', we have

$$P(S^n_Z \in (E^{R,d})^c) \vee P(S^n_W \in (E^{R,d})^c) = C_1 d \exp(-C_2 R d^{1/2}).$$

By setting $V_{(s_0,p)}^{z,d} = \{x \in \mathbb{R}^d : \|x\|_{(s_0,p)} \leq z\}$, we then have

$$\sup_z \left| P(S^n_Z \in V_{(s_0,p)}^{z,d}) - P(S^n_W \in V_{(s_0,p)}^{z,d}) \right| \leq A_1 + A_2,$$

where $A_1 = C_1 d \exp(-C_2 R d^{1/2})$ and $A_2 = \sup_z P_z$ with

$$P_z = |P(S^n_Z \in E^{R,d} \cap V_{(s_0,p)}^{z,d}) - P(S^n_W \in E^{R,d} \cap V_{(s_0,p)}^{z,d})|.$$

We then approximate $E^{R,d} \cap V_{(s_0,p)}^{z,d}$ with $m$-generated convex set. According to Lemmas A.3 and A.4, by setting $\bar{\rho} = |P(S^n_Z \in A^m) - P(S^n_W \in A^m)| \vee |P(S^n_Z \in A^{m,Re}) - P(S^n_W \in A^{m,Re})|$, we have $P_z \leq C R \epsilon \log^{1/2}(m) + \bar{\rho}$, where $C$ only depends on $b$. By high dimensional CLT for Hyperrectangles in [7], we have

$$\bar{\rho} \leq C \left( \frac{\log^7(mn)}{n} \right)^{1/6},$$

where $C$ only depends on $b$. Considering (E.1), we then have

$$\sup_z \left| P(S^n_Z \in V_{(s_0,p)}^{z}) - P(S^n_W \in V_{(s_0,p)}^{z}) \right| \leq C R \epsilon \log^{1/2}(m) + C \left( \frac{\log^7(mn)}{n} \right)^{1/6} + C_1 d \exp(-C_2 R d^{1/2}).$$

By setting $\epsilon = (dn)^{-3/2}$ and $R = (dn)^{1/2}$, considering $s_0^2 \log(dn) = O(n^\zeta)$ with $0 < \zeta < 1/7$, we have

$$R \epsilon \log^{1/2}(m) \leq \left( \frac{\log^7(mn)}{n} \right)^{1/6}, \quad d \exp(-C_2 R d^{1/2}) \leq \left( \frac{\log^7(mn)}{n} \right)^{1/6},$$

which yields (A.1).

E.2. Proof of Lemma A.3.

PROOF. By the definition of $m$-generated convex sets $A^m$ and $A^{m,\epsilon}$, Lemma A.3 is an immediate corollary of Lemma A.2. □
E.3. Proof of Lemma A.5.

**Proof.** By the Jensen’s inequality, we have

\[
\exp \left( t \mathbb{E} \left[ \max_{1 \leq i \leq d} |W_i| \right] \right) \leq \mathbb{E} \left[ \exp \left( t \max_{1 \leq i \leq d} |W_i| \right) \right] \leq d \mathbb{E} \left[ \exp (t |W_i|) \right].
\]

By (23) of [12], we have

\[
\mathbb{E} [\exp (t |W_i|)] = 2 e^{\frac{s^2 t^2}{2}} \sigma^2 \left[ 1 - \Phi(-\sigma t) \right] \leq 2 e^{\frac{s^2 t^2}{2}}.
\]

Combining (E.2) and (E.3), we have

\[
\exp \left( t \mathbb{E} \left[ \max_{1 \leq i \leq d} |W_i| \right] \right) \leq 2d e^{\frac{s^2 t^2}{2}},
\]

which yields (A.2).

\[\square\]

E.4. Proof of Lemma A.6.

**Proof.** We first prove for \( m > 1 \). For simplicity, we only present the proof for \( X \). In (3.4), we set \( \Sigma_1 = (\sigma_{1,st}) \) with

\[
\sigma_{1,st} = \mathbb{E} [h_s(X) h_t(X)],
\]

where \( h_s \) is defined in (3.1). To estimate \( \Sigma_1 \), in (3.9) we introduce \( \tilde{\Sigma}_1 := (\tilde{\sigma}_{1,st}) \in \mathbb{R}^{q \times q} \), where \( \tilde{\sigma}_{1,st} = n_1^{-1} \sum_{k=1}^{n_1} (Q_{1k,s} - \tilde{u}_{1,s})(Q_{1k,t} - \tilde{u}_{1,t}) \). By setting \( \tilde{u}_{1,s} = \tilde{u}_{1,s} - u_{1,s} \) and \( \tilde{Q}_{1k,s} = Q_{1k,s} - u_{1,s} \), we rewrite \( \tilde{\sigma}_{1,st} \) as

\[
\tilde{\sigma}_{1,st} = n_1^{-1} \sum_{k=1}^{n_1} \tilde{Q}_{1k,s} \tilde{Q}_{1k,t} - \tilde{u}_{1,s} \tilde{u}_{1,t}.
\]

To provide an upper bound for \( \max_{1 \leq s,t \leq q} |\tilde{\sigma}_{1,st} - \sigma_{1,st}| \), by combining (E.4) and (E.5), we use the triangle inequality to obtain

\[
\max_{1 \leq s,t \leq q} |\tilde{\sigma}_{1,st} - \sigma_{1,st}| \leq \max_{1 \leq s,t \leq q} \left| n_1^{-1} \left( \sum_{k=1}^{n_1} \tilde{Q}_{1k,s} \tilde{Q}_{1k,t} - \mathbb{E}[h_s(X) h_t(X)] \right) \right|_{L_1} + \max_{1 \leq s,t \leq q} \left| \tilde{u}_{1,s} \tilde{u}_{1,t} \right|_{L_2}.
\]
We then bound $L_1$ and $L_2$ separately. For bounding $L_2$, we introduce

$$
\tilde{u}_{1,s} = \left( \frac{n_1}{m} \right)^{-1} \sum_{1 \leq i_1 < \ldots < i_m \leq n_1} V_{1,i_1 \ldots, i_m} - E_{1,s},
$$

where $V_{1,i_1 \ldots, i_m}$ and $E_{1,s}$ are defined in (C.3) with threshold $B_n = C \log(qn)$. For any $\delta > 0$, by choosing proper $C$, we have $E_{1,s} < (qn)^{-\delta}$. We then have

$$
|\tilde{u}_{1,s} - \tilde{u}_{i,s}^t| \leq \left| \tilde{u}_{1,s} - \left( \frac{n_1}{m} \right)^{-1} \sum_{1 \leq i_1 < \ldots < i_m \leq n_1} V_{1,i_1 \ldots, i_m} \right| + E_{1,s},
$$

where $L_{2,s}$.

By setting $z > (qn)^{-\delta}$, we have

$$
(E.6) \quad \max_{1 \leq s \leq q} \mathbb{P}(|\tilde{u}_{1,s}| > z) \leq \max_{1 \leq s \leq q} \left( \mathbb{P}(|\tilde{u}_{1,s}^t| > z/3) + \mathbb{P}(L_{2,s} > z/3) \right).
$$

By using the exponential inequality for bounded $U$-statistics we have

$$
(E.7) \quad \max_{1 \leq s \leq q} \mathbb{P}(|\tilde{u}_{1,s}^t| > z/3) \leq C \exp(-C_1 n z^2 / B_n^2).
$$

By Assumption (E), we also have

$$
(E.8) \quad \max_{1 \leq s \leq q} \mathbb{P}(L_{2,s} > z/3) \leq C n_1^m \exp(-C_1 B_n)
$$

Combining (E.6), (E.7), and (E.8), we then have

$$
P(L_2 > y) \leq q^2 \max_{1 \leq s \leq q} \mathbb{P}(|\tilde{u}_{1,s} u_{1,t}| > y) \leq 2q^2 \max_{1 \leq s \leq q} \mathbb{P}(|\tilde{u}_{1,s}| > \sqrt{y})
$$

$$
\leq C q^2 \exp(-C_1 n y / B_n^2) + C q^2 n_1^m \exp(-C_1 B_n).
$$

Therefore, for sufficiently large $n_1$ with probability $1 - C n_1^{-1}$ we have $L_2 \leq \log^3(qn)/n$.

We now bound $L_1$. Considering that $n_1^{-1} \sum_{k=1}^{n_1} h_s(X_k) h_t(X_k)$ approximates $E[h_s(X_k) h_t(X_k)]$, we use triangle inequality again to bound $L_1$ by

$$
L_1 \leq \max_{1 \leq s, t \leq q} \left| n_1^{-1} \left( \sum_{k=1}^{n_1} \tilde{Q}_{k,s} \tilde{Q}_{k,t} \right) - n_1^{-1} \sum_{k=1}^{n_1} h_s(X_k) h_t(X_k) \right|
$$

$$
+ \max_{1 \leq s, t \leq q} \left| n_1^{-1} \sum_{k=1}^{n_1} h_s(X_k) h_t(X_k) - E[h_s(X) h_t(X)] \right|.
$$

(E.10)
By Assumption (E), $h_s(X)$ has sub-exponential tails. Therefore, by Theorem 6 in [9], we have

(E.11)  $\mathbb{P}(L_4 > z) \leq C q^2 \exp(-C_1 n_1 z^2) + C q^2 \exp\left(-C_2(n_1 z)^{1/2}\right)$.

Therefore, for sufficiently large $n_1$, with probability $1 - C n_1^{-1}$, we have

\[ L_4 \leq C \sqrt{\frac{\log(qn)}{n}} + C_1 \frac{\log^2(qn)}{n}. \]

After bounding $L_4$, we now deal with $L_3$. For this, we decompose $\tilde{Q}_{1k,s}$ as

(E.12)  $\tilde{Q}_{1k,s} = \left( \frac{n_1 - 1}{m - 1} \right)^{-1} (Ah_s(X_k) + BS_{1,s} + \Sigma_{1,s}^{(k)})$,

with $A = \left( \frac{n_1 - 1}{m - 1} \right) - \left( \frac{n_1 - 2}{m - 2} \right)$, $B = \left( \frac{n_1 - 1}{m - 1} \right)$, $S_{1,s} := \sum_{\beta=1}^{n_1} h_s(X_{\beta})$ and

(E.13)  $\Sigma_{1,s}^{(k)} = \sum_{1 \leq t_1 < \ldots < t_{m-1} \leq n_1} \left( \Gamma_{1,s}^{k,t_1t_2\ldots t_{m-1}} \right)$,

with $\Gamma_{1,s}^{k,t_1t_2\ldots t_{m-1}} = \Psi_s(X_k, X_{t_1}, \ldots, X_{t_{m-1}}) - (h_s(X_k) + \sum_{i=1}^{m-1} h_s(X_{t_i}))$.

$\Psi_s(X_{k_1}, \ldots, X_{k_m})$, the centralized version of $\Phi_s(X_{k_1}, \ldots, X_{k_m})$, is defined in (3.1). For notational simplicity, by setting

(E.14)  $V_{1,st}^2 := \sum_{k=1}^{n_1} h_s(X_k) h_t(X_k)$, $\Lambda_{1,s} := \sum_{k=1}^{n_1} \Sigma_{1,s}^{(k)}$, $\Lambda_{1,st}^2 := \sum_{k=1}^{n_1} \Sigma_{1,s}^{(k)} \Sigma_{1,t}^{(k)}$,

and $D = \left( \frac{n_1 - 1}{m - 1} \right)$. we have $L_3 = \max_{1 \leq s,t \leq q} L_{3,st}$, where $L_{3,st}$ is defined as

\[ \left| \frac{1}{n_1} \left( \frac{1}{D^2} \sum_{k=1}^{n_1} (Ah_s(X_k) + BS_{1,s} + \Sigma_{1,s}^{(k)}) (Ah_t(X_k) + BS_{1,t} + \Sigma_{1,t}^{(k)}) - \sum_{k=1}^{n_1} h_s(X_k) h_t(X_k) \right) \right|. \]

After introducing these notations, we can expand $L_{3,st}$ as

\[ L_{3,st} = \left| \frac{A^2}{n_1 D^2} V_{1,st}^2 + \frac{1}{n_1 D^2} (2AB + n_1 B^2) S_{1,s} S_{1,t} + \frac{1}{n_1 D^2} \Lambda_{1,st}^2 
+ \frac{A}{n_1 D^2} \sum_{k=1}^{n_1} (\Sigma_{1,s}^{(k)} h_t(X_k) + \Sigma_{1,t}^{(k)} h_s(X_k)) + \frac{B}{n_1 D^2} (\Lambda_{1,s} S_{1,t} + \Lambda_{1,t} S_{1,s}) \right|. \]
By using the triangle inequality on $L_{3, st}$, we have $L_{3, st} \leq J_{1, st} + J_{2, st} + J_{3, st} + J_{4, st} + J_{5, st}$, where

$$J_{1, st} := \left| \frac{A^2 - D^2}{n_1 D^2} V_{1, st}^2 \right|, \quad J_{2, st} := \left| \frac{2AB + n_1 B^2}{n_1 D^2} S_{1, s} S_{1, t} \right|, \quad J_{3, st} := \left| \frac{1}{n_1 D^2} \Lambda^2_{1, st} \right|, \quad J_{4, st} := \left| \frac{A}{n_1 D^2} \sum_{k=1}^{n_1} (\Upsilon^{(k)}_{1, s} h_t(X_k) + \Upsilon^{(k)}_{1, t} h_s(X_k)) \right|, \quad J_{5, st} := \left| \frac{B}{n_1 D^2} (\Lambda_{1, s} S_{1, t} + \Lambda_{1, t} S_{1, s}) \right|.$$ 

We now bound $J_{1, st}, \ldots, J_{5, st}$ separately. By the definitions of $A$ and $D$, we obtain

$$A = O(n_1^{m-1}), \quad D = O(n_1^{m-1}) \quad \text{and} \quad D - A = \left( \frac{n_1 - 2}{m - 2} \right) = O(n_1^{m-2}).$$

Thus, for $J_{1, st}$, by the definition of $V_{1, st}$ in (E.14), by Assumption (M2) we easily have that $\max_{1 \leq s, t \leq q} J_{1, st} = O_p(n_1^{-1})$. For $J_{2, st}$, considering $B = O(n_1^{m-2})$, we use the exponential inequality to have

(E.15) \quad \Pr(J_{2, st} > y) = \Pr\left( \frac{S_{1, s} S_{1, t}}{n_1^2} \geq Cy \right) \leq C_1 \exp(-C_2 n_1 \min(y, \sqrt{y})).

With probability $1 - Cn_1^{-1}$, we then have $\max_{1 \leq s, t \leq q} J_{2, st} \leq \log(qn_1) n_1^{-1}$ for sufficiently large $n_1$. We then bound $J_{3, st}$. Recalling $\Lambda_{1, st} := \sum_{k=1}^{n_1} \Upsilon^{(k)}_{1, s} \Upsilon^{(k)}_{1, t}$ in (E.14), we have

$$\Pr(J_{3, st} > y) = \Pr\left( \frac{\Lambda_{1, st}^2}{n_1^{2m-1}} \geq Cy \right) = \Pr\left( \sum_{k=1}^{n_1} \Upsilon^{(k)}_{1, s} \Upsilon^{(k)}_{1, t} \geq C n_1^{2m-1} y \right) \leq \sum_{k=1}^{n_1} \Pr\left( \Upsilon^{(k)}_{1, s} \Upsilon^{(k)}_{1, t} \geq C n_1^{2m-2} y \right).$$

By the definition of $\Upsilon^{(k)}_{1, s}$ in (E.13), given $X_k$, we can treat

$$\Psi_s(X_k, X_{\ell_1}, \ldots, X_{\ell_{m-1}}) - (h_{ij}(X_k) + \sum_{r=1}^{m-1} h_{ij}(X_{\ell_r})),$$ 

as a symmetric kernel function. Therefore, $\Upsilon^{(k)}_{1, s}/D|X_k$ is a $U$-statistic with a kernel function of zero mean and $m - 1$ order. Hence, similarly to $L_2$, we threshold the kernel with $C \log(qn_1)$ and use the exponential inequality.
for $U$-statistics to obtain that for sufficiently large $n_1$ with probability with $1 - C_1 n_1^{-1}$, we have

$$\max_{1 \leq s, t \leq q} J_{3, st} \leq C \frac{\log^2(qn)}{n}.$$  

We now bound $J_{4, st}$ and $J_{5, st}$. For $J_{4, st}$, we use the Cauchy-Swartz inequality on $\sum_{k=1}^{n_1} Y_{1, s}^{(k)} h_t(X_k)$ and $\sum_{k=1}^{n_1} Y_{1, t}^{(k)} h_s(X_k)$ to obtain

(E.16) $$J_{4, st} \leq \left| \frac{A}{n_1 D^2} (\Lambda_{1, ss} V_{1, tt} + \Lambda_{1, tt} V_{1, ss}) \right|.$$  

For $J_{5, st}$, by using the Cauchy-Swartz inequality on $\Lambda_{1, s}$ and $S_{1, s}$, we have

(E.17) $$J_{5, st} \leq \left| \frac{B}{D^2} (\Lambda_{1, ss} V_{1, tt} + \Lambda_{1, tt} V_{1, ss}) \right|.$$  

Combining (E.16) and (E.17), we have

(E.18) $$J_{4, st} + J_{5, st} \leq \left| \frac{A + n_1 B}{n_1 D^2} (\Lambda_{1, ss} V_{1, tt} + \Lambda_{1, tt} V_{1, ss}) \right|.$$  

Considering $A = O(n_1^{m-1})$, $B = O(n_1^{m-2})$, and $D = O(n_1^{m-1})$, by the triangle inequality we have

$$\max_{1 \leq s, t \leq q} J_{6, st} \leq C \max_{1 \leq s, t \leq q} \frac{\Lambda_{1, ss}}{n_1^m} V_{1, tt} = \left( \max_{1 \leq s, t \leq q} \frac{\Lambda_{1, ss}^2}{n_1^{2m-3/2}} \max_{1 \leq s, t \leq q} \frac{V_{1, ss}^2}{n_1^{3/2}} \right)^{1/2}.$$  

Similarly to $L_4$, from Assumption (M2), we have $\max_{1 \leq s \leq q} J_{6, s}^n = O_p(n_1^{-1/2})$. For $J_{6, s}$, we have

(E.19) $$\mathbb{P}\left( \frac{\Lambda_{1, ss}^2}{n_1^{2m-3/2}} \geq y \right) \leq \sum_{k=1}^{n_1} \mathbb{P}\left( \frac{|Y_{1, ss}^{(k)}|}{n_1^{m-1}} \geq C n_1^{-1/4} y^{1/2} \right).$$  

By thresholding kernel with $C \log(qn)$ and exponential inequality for $U$-statistics, for sufficiently large $n_1$, $\max_{1 \leq s, t \leq q} J_{6, s}^n \leq \log^3(qn_1) n_1^{-1/2}$ holds with probability $1 - C_1 n_1^{-1}$. Therefore, we have

$$\max_{1 \leq s, t \leq q} J_{6, st} \leq C \log^{3/2}(qn_1) n_1^{-1/2}.$$
Combining (E.20), (E.21), and (E.22), we then have that

\[
A \leq B b > 0, \text{by Assumption (M1)}
\]

Therefore, we have

\[
\max_{1 \leq s, t \leq q} |\hat{\sigma}_{1,st} - \sigma_{1,st}| \leq C \frac{\log^{3/2}(qn_1)}{\sqrt{n_1}}.
\]

After analyzing the approximation error of \(\hat{\sigma}_{1,st}\), we then prove for \(\hat{\tau}_{1,st}\). By (A.3), we have \(\hat{\tau}_{1,st} = \sigma_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}}\) and \(r_{1,st} = \sigma_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}}\). Therefore, we have

\[
|\hat{\tau}_{1,st} - r_{1,st}| = \frac{|\hat{\sigma}_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}} - \sigma_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}}|}{\sqrt{\sigma_{1,ss}\sigma_{1,tt}}} + \frac{|\hat{\sigma}_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}} - \sigma_{1,st}/\sqrt{\sigma_{1,ss}\sigma_{1,tt}}|}{\sqrt{\sigma_{1,ss}\sigma_{1,tt}}}.
\]

Hence, to bound \(|\hat{\tau}_{1,st} - r_{1,st}|\) we bound \(A_1\) and \(A_2\) separately. For \(A_1\), we rewrite it as

\[
A_1 = \left| \frac{\hat{\sigma}_{1,st}}{\sqrt{\sigma_{1,ss}\sigma_{1,tt}}} \right| \left| 1 - \frac{\sqrt{\sigma_{1,ss}\sigma_{1,tt}}}{\sqrt{\sigma_{1,ss}\sigma_{1,tt}}} \right|.
\]

Considering \(|\hat{\tau}_{1,st}| \leq 1\) and \(a^2 - b^2 = (a + b)(a - b)\), we have

\[
A_1 \leq \sigma_{1,ss}^{-1} |\hat{\sigma}_{1,ss}\sigma_{1,tt} - \sigma_{1,ss}\sigma_{1,tt}|.
\]

By Assumption (M1) and (M2), there are constants \(b\) and \(B\), such that \(0 < b \leq \sigma_{1,ss} \leq B < \infty\) for \(s = 1, \ldots, q\). Hence, we have

\[
A_1 \leq b^{-2} \max_{1 \leq s \leq q} \left| \hat{\sigma}_{1,ss} - \sigma_{1,ss} \right|^2 + 2 B b^{-2} \max_{1 \leq s \leq q} \left| \hat{\sigma}_{1,ss} - \sigma_{1,ss} \right|.
\]

For \(A_2\), by \(\sigma_{1,ss} \geq b > 0\) from Assumption (M1) we have

\[
A_2 \leq b^{-1} \max_{1 \leq s, t \leq q} |\hat{\sigma}_{1,st} - \sigma_{1,st}|.
\]

Combining (E.20), (E.21), and (E.22), we then have that

\[
\max_{1 \leq s, t \leq q} |\hat{\tau}_{1,st} - r_{1,st}| \leq C \frac{\log^{3/2}(qn_1)}{\sqrt{n_1}},
\]

holds with the overwhelming probability, which finishes the proof for \(m > 1\).

We then prove for \(m = 1\). We decompose \(\hat{\sigma}_{1,st}\) as

\[
\hat{\sigma}_{1,st} = n_1^{-1} \sum_{k=1}^{n_1} \Psi_s(X_k)\Psi_t(X_k) - \Psi_{1,s}^T \Psi_{1,t}.
\]
where $\Psi_s(X_k) = \Phi_s(X_k) - u_{1,s}$ and $\overline{\Psi}_{1,s} = n_1^{-1} \sum_{k=1}^{n_1} \Psi_s(X_k)$. Considering $\sigma_{1,st} = \mathbb{E}[\Psi_s(X)\Psi_t(X)]$, by setting

$$B_1 = \mathbb{P}\left( \max_{1 \leq s,t \leq q} |n_1^{-1} \sum_{k=1}^{n_1} \Psi_s(X_k)\Psi_t(X_k) - \mathbb{E}[\Psi_s(X)\Psi_t(X)]| > x/2 \right)$$

$$B_2 = \mathbb{P}\left( \max_{1 \leq s,t \leq q} \overline{\Psi}_{1,s}\overline{\Psi}_{1,t} > x/2 \right)$$

we then have

$$(E.23) \quad \mathbb{P}\left( \max_{1 \leq s,t \leq q} |\hat{\sigma}_{\gamma,st} - \sigma_{\gamma,st}| > x \right) \leq B_1 + B_2,$$

By Theorem 6 in [9], we can bound $B_1$ by

$$(E.24) \quad B_1 \leq Cq^2 \exp(-C_1 n_1 x^2) + Cq^2 \exp(-C_2(n_1 x)^{1/2}).$$

Similarly, for the term $B_2$ in (E.23), we use the same argument to obtain

$$(E.25) \quad \mathbb{P}\left( \max_{1 \leq s,t \leq q} \overline{\Psi}_{1,s}\overline{\Psi}_{1,t} > x/2 \right) \leq Cq^2 \exp(-C_1 n_1 x) + Cq^2 \exp(-C_2(n_1 \sqrt{x})).$$

Combining (E.23), (E.24), and (E.25), for sufficiently large $n_1$, with probability $1 - C_1 n_1^{-1}$, we have

$$(E.26) \quad \max_{1 \leq s,t \leq q} |\hat{\sigma}_{1,st} - \sigma_{1,st}| \leq C \sqrt{\frac{\log(qn_1)}{n_1}} + C \frac{\log^2(qn_1)}{n_1}.$$

Similarly to $m > 1$, we also have that

$$\max_{1 \leq s,t \leq q} |\hat{r}_{1,st} - r_{1,st}| \leq C \sqrt{\frac{\log(qn_1)}{n_1}} + C \frac{\log^2(qn_1)}{n_1},$$

holds with the overwhelming probability for $m = 1$. \qed

**APPENDIX F: MORE SIMULATION RESULTS**

This section consists of three parts. Firstly, we present the empirical size for high dimensional mean tests based on **Models 2-4**, which are introduced in Section 4. Secondly, we apply our methods to test high dimensional covariance/correlation coefficients to illustrate the generality of proposed methods. At last, we apply our methods to analyze resting-state functional magnetic resonance imaging (fMRI) data.
Table 3

F.1. Additional simulation results of testing high dimensional mean values. In Section 4, we introduce Models 1-4 for high dimensional mean tests. In this section, we show the numerical results for Models 2-4 in Table 3.

F.2. Simulation results of testing high dimensional covariance and correlation coefficients. In this section, we carry out the simulation of the marginal test using the Pearson’s covariance and Kendall’s tau correlation matrices. For simplicity, we consider the one-sample problem. In the simulation, $Z$ and $X \in \mathbb{R}^d$ are the response variable and the explanatory vector. We generate $n_1$ data points of $(Z, X^\top)^\top$ from the following models.

- **Model 5.** Let $\Sigma_0^L, \Sigma_1^L \in \mathbb{R}^{(d+1)\times (d+1)}$ to be
  
  
  $\Sigma_0^L = \begin{bmatrix} 1 & 0^\top \\ 0 & (D^*)^{-1/2} \Sigma^*(D^*)^{-1/2} \end{bmatrix}, \quad \Sigma_1^L = \begin{bmatrix} 1 & V^\top \\ V & (D^*)^{-1/2} \Sigma^*(D^*)^{-1/2} \end{bmatrix},$

  where $V \in \mathbb{R}^d$ has $s$ nonzero entries with the magnitude $U(u_1,u_2)$. Under the null hypothesis, we generate $n_1$ random vectors from $t(\nu, \mu, \Sigma)$ with $\nu = 5, \mu = 0, \Sigma = \Sigma_0^L$ as the samples of $(Z, X^\top)^\top$. Under the alternative hypothesis, we generate the samples of $(Z, X^\top)^\top$ from $t(5, 0, \Sigma_1^L + \delta I_{d+1})$ with $\delta = |\lambda_{\min}(\Sigma_1^L)| + 0.5$.

  The experimental results of Model 5 are in Table 4. In Model 5 we compare the proposed tests based on Pearson’s covariance and Kendall’s tau correlation matrices. The pattern of empirical size and power for Model 5 is similar to Models 1-4. Moreover, the experiment shows that Kendall’s tau based test is more powerful than the Pearson’s covariance based one for distributions with the heavy tails and strong tail dependence.

F.3. Simulation results of increasing $\#(P)$. In this section, we discuss the impact of $\#(P)$ by simulation. In Sections 2.2 and 3.3, we require fixed $P$ for the data-adaptive combined test. In Remark 3.6, we discuss theoretical difficulties of increasing $\#(P)$. In this section, we present the performance of proposed methods under various $P$.

For this we generate the data based on Model 1 in Section 4. We consider various $P$. In detail, we set $P_1 = \{1, 2\}, P_2 = \{1, 2, \infty\}, P_3 = \{1, 2, 3, 4, 5\}, P_4 = \{1, 2, 3, 4, 5, \infty\}, P_5 = \{1, 2, \ldots, 10, \infty\}$, and $P_6 = \{1, 2, \ldots, 20, \infty\}$. We also consider various alternatives with $s = 5, 50, 100$, from sparse to dense. The simulation results are in Table 5.

From Table 5, we recommend using $P_4 = \{1, 2, 3, 4, 5, \infty\}$. It has good performance for both sparse and dense alternatives. Table 5 also shows that there is no power advantage to add more elements to $P_4$.

F.4. Real data example. In this section, we apply our methods to analyze resting-state functional magnetic resonance imaging (fMRI) data. We aim to compare the resting-state fMRI scans between the attention deficit hyperactivity disorder (ADHD) and normal children. For each subject, the resting-state fMRI scan is a high dimensional time series. Instead of dealing with the time series directly, we alternatively use an index named amplitude of low frequency fluctuation (ALFF) to yield a high dimensional vector for each subject. Each entry of ALFF is defined as the total power within the frequency range between 0.01 and 0.1 Hz of the corresponding entry of the original fMRI time series, which reflects the slow fluctuation. In general, ALFF reflects the intensity of regional spontaneous brain activity. As for the detailed definition of ALFF, we refer to [13]. Existing literature [13, 14] utilizes univariate two-sample $t$ -tests to detect differentially expressed brain areas between the diseased and control groups based on ALFF. Before we conduct the univariate two-sample tests, it is a common practice to perform a global test to verify that there is significant difference of ALFFs between two groups. By the definition of ALFF, we utilize the high dimensional mean test to perform the global test.

Our experiment is based on the first dataset of Peking University from the ADHD-200 sample. The sample consists of 85 subjects, in which 24 subjects have ADHD. Therefore, the control group has 61 subjects. ALFF analysis is performed by using the C-PAC software. The C-PAC software preprocesses the data by registering each person’s fMRI scan to the standard MN152 template. To increase the signal-noise ratio, the software also performs slice timing correction, body motion correction, nuisance signal correction, and temporal filtering. Because of the difference of individual brain baseline activity, we standardize the ALFF for each subject. We then use the Gaussian kernel to perform the spatial smoothing for each subject. Moreover, existing literature and psychological knowledge suggest that the ALFF of brain’s gray matter is related to the mental disease. Hence, we restrict the testing area to the gray matter of the brain. For detailed description of the processing procedure, we refer to [13], [14], and the user guide of C-PAC software.

Figure 3 illustrates $P$-values of univariate two-sample $t$-tests. Figure 3(A) illustrates the $P$-value map to the standard MN152 brain template with the slice thickness 3mm at the given threshold ($P$-value < 0.2). Moreover, Figure 3(B) illustrates the estimated density of these $P$-values. Figure 3 shows there are significant ALFF differences between the diseased and control groups in

---

Fig 3. *P*-values of the marginal two-sample *t*-tests on ALFFs between ADHD and control groups. (A) The *P*-value map on the standard MN152 brain template with the slice thickness 3mm at the given threshold (*P*-value < 0.2). (B) The estimated density of the *P*-values and some summary statistics.
some brain areas.

Table 6

| $s_0$ | $p = 1$ | $p = 2$ | $p = 3$ | $p = 4$ | $p = 5$ | $p = \infty$ | $T^N_{ad}$ |
|-------|---------|---------|---------|---------|---------|-------------|---------|
| 40    | 0.001   | 0.001   | 0.001   | 0.001   | 0.001   | 0.001       | 0.000   |
| 400   | 0.013   | 0.013   | 0.012   | 0.011   | 0.011   | 0.011       | 0.000   |
| 4000  | 0.016   | 0.016   | 0.016   | 0.016   | 0.016   | 0.016       | 0.000   |
| 8000  | 0.016   | 0.016   | 0.016   | 0.016   | 0.016   | 0.016       | 0.000   |

We then use both the individual $(s_0, p)$-norm test and data-adaptive combined test with balanced $\mathcal{P} = \{1, \ldots, 5, \infty\}$ to perform the global test. We also randomly split the sample for the control group into two subsamples with 30 and 31 subjects. We then perform the global mean test between the two subsamples of the control group to confirm the validity of our proposed methods. As is shown in Figure 3, at most 20% of the gray matter is potentially different between the diseased and control groups. Therefore, considering that the voxel size is about 40000, we set $s_0 = 40, 400, 4000, 8000$ in the experiment. The experiment result is presented in Table 6, which shows that our proposed methods are quite powerful to distinguish the ADHD and control groups.
