Abstract  Searches for the direct electroweak production of supersymmetric charginos, neutralinos, and sleptons in a variety of signatures with leptons and W, Z, and Higgs bosons are presented. Results are based on a sample of proton-proton collision data collected at center-of-mass energy \( \sqrt{s} = 8\text{ TeV} \) with the CMS detector in 2012, corresponding to an integrated luminosity of 19.5 fb\(^{-1}\). The observed event rates are in agreement with expectations from the standard model. These results probe charginos and neutralinos with masses up to 720 GeV, and sleptons up to 260 GeV, depending on the model details.

1 Introduction

Many searches for supersymmetry (SUSY) [1–5] carried out at the CERN Large Hadron Collider (LHC) have focused on models with cross sections dominated by the production of strongly interacting new particles in final states with high levels of hadronic activity [6–17]. Null results from these searches constrain the squarks and gluinos to be heavier than several hundred GeV. In contrast, in this paper, we describe searches motivated by the direct electroweak production of charginos \( \tilde{\chi}^\pm \) and neutralinos \( \tilde{\chi}^0 \), mixtures of the SUSY partners of the gauge and Higgs bosons, and of sleptons \( \tilde{\ell} \), the SUSY partners of leptons. These production modes may dominate at the LHC if the strongly interacting SUSY particles are heavy. The corresponding final states do not necessarily contain much hadronic activity and thus may have eluded detection.

The smaller cross sections typical of direct electroweak SUSY production require dedicated searches targeting the wide variety of possible signal topologies. Depending on the mass spectrum, the charginos and neutralinos can have significant decay branching fractions to leptons or W, Z, and Higgs bosons (H), yielding final states with at least one isolated lepton. Similarly, slepton pair production gives rise to final states with two leptons. In all these cases, and under the assumption of R-parity conservation [5], two stable, lightest SUSY particles (LSP) are produced, which are presumed to escape without detection, leading to significant missing transverse energy \( E_T^{\text{miss}} \). We thus search for SUSY in a variety of final states with one or more leptons and \( E_T^{\text{miss}} \).

The searches are based on a sample of proton–proton (pp) collision data collected at \( \sqrt{s} = 8\text{ TeV} \) with the Compact Muon Solenoid (CMS) detector at the LHC in 2012, corresponding to an integrated luminosity of 19.5 fb\(^{-1}\). The study is an update of Ref. [18], with improvements to the analysis techniques and the addition of new signal scenarios and search channels. Similar studies in the two-lepton, three-lepton, and four-lepton final states have been performed by the ATLAS Collaboration [19–21]. The new-physics scenarios we consider are shown in Figs. 1, 2 and 3. These figures are labeled using SUSY nomenclature, but the interpretation of our results can be extended to other new-physics models. In SUSY nomenclature, \( \tilde{\chi}_1^0 \) is the lightest neutralino, presumed to be the LSP, \( \tilde{\chi}_2^0 \) is a heavier neutralino, \( \tilde{\chi}_1^\pm \) is the lightest chargino, and \( \tilde{\ell} \) is a slepton. We also consider a model in which the gravitino (\( \tilde{G} \)) is the LSP.

The results are interpreted considering each diagram in Figs. 1, 2 and 3 individually. The masses of the new-physics particles are treated as independent parameters. SUSY models with a bino-like \( \tilde{\chi}_1^0 \) and wino-like \( \tilde{\chi}_2^0 \) and \( \tilde{\chi}_1^\pm \) motivate the simplifying assumption \( m_{\tilde{\chi}} \equiv m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0} \) since these two gauginos belong to the same gauge group multiplet. We thus present results as a function of the common mass \( m_{\tilde{\chi}} \) and the LSP mass \( m_{\tilde{\chi}_1^0} \).

In the models shown in Figs. 1 and 3 (top), the slepton mass \( m_{\tilde{\ell}} \) is less than the common mass \( m_{\tilde{\chi}} \), and the sleptons are produced in the decay chains of the charginos and neutralinos. The results in these scenarios also depend on the mass \( m_{\tilde{\ell}} \) of the intermediate slepton (if left-handed, taken to be the same for its sneutrino \( \tilde{\nu} \)), parametrized in terms of a variable \( x_{\tilde{\ell}} \) as:

Chargino–neutralino pair production with decays mediated by sleptons and sneutrinos, leading to a three-lepton final state with missing transverse energy $E_T^{\text{miss}}$.

For the models in Fig. 2, we assume that sleptons are so massive that diagrams containing virtual or real sleptons in the chargino or neutralino decay process can be ignored. In Fig. 2 (top and center), the chargino decays to a W boson and the LSP, while the neutralino may decay either to a Z or H boson and the LSP, with branching fractions that depend on model details. The H boson is identified with the lightest neutral CP-even state of extended Higgs sectors. The H boson is expected to have SM Higgs boson properties if all other Higgs bosons are much heavier \[22\]. We thus search in both the $WZ + E_T^{\text{miss}}$ and $WH + E_T^{\text{miss}}$ signatures. There is little sensitivity to the $ZZ$ channel of Fig. 2 (bottom) if the $\tilde{\chi}^0_2$ and $\tilde{\chi}^\pm_1$ are wino-like, in which case neutralino pair production is suppressed relative to neutralino–chargino production. Therefore, for the $ZZ$ signature, we consider a specific gauge-mediated supersymmetry breaking (GMSB) model with higgsino next-to-lightest SUSY particles (NLSP) and a gravitino LSP \[23–25\], which enhances the $ZZ + E_T^{\text{miss}}$ production rate. In this model, the $\tilde{\chi}^0_1$ then decays to a Z boson and the gravitino LSP. The production of the $HH + E_T^{\text{miss}}$ and $ZH + E_T^{\text{miss}}$ final states is also possible in the GMSB model, depending on the character of the NLSP. These latter two final states are not considered in the current study.

Figure 3 (top) depicts chargino pair production. For this process, each chargino can decay via either of the two modes shown. Thus, there are four different decay pairs, but all yield a similar final state, with two opposite-sign leptons and $E_T^{\text{miss}}$.

$$m_{\tilde{\chi}} = m_{\tilde{\chi}^0} + x_{\tilde{\chi}} (m_{\tilde{\chi}^0} - m_{\tilde{\chi}^0}),$$

where $0 < x_{\tilde{\chi}} < 1$. We present results for $x_{\tilde{\chi}} = 0.50$, i.e., the slepton mass equal to the mean of the LSP and the $\tilde{\chi}$ masses, and in some cases for more compressed spectra with $x_{\tilde{\chi}} = 0.05$ or 0.95, i.e., the slepton mass close to either the LSP or the $\tilde{\chi}$ mass, respectively.
of this analysis are not sensitive to the direct production of \( \tau \)-slepton pairs.

This paper is organized as follows. In Sect. 2, we describe the detector, data and simulated samples, and event reconstruction procedures. Section 3 presents a search based on the three-lepton final states of Figs. 1 and 2 (top). A search based on the four-lepton final state, which is sensitive to the diagram of Fig. 2 (bottom), is presented in Sect. 4. Section 5 describes a search in a channel with exactly two same-sign dileptons, which enhances sensitivity to the diagrams of Fig. 1 in cases where one of the three leptons is not identified. In Sect. 6 we present a search based on the \( WZ/ZZ + E_T^{\text{miss}} \) signature, which is sensitive to the diagrams shown in Fig. 2 (top and bottom). Section 7 presents a set of searches targeting WH+\( E_T^{\text{miss}} \) production in the single-lepton, same-sign dilepton, and three-or-more-lepton channels, probing the diagram of Fig. 2 (center). In Sect. 8, we present a search based on an opposite-sign, non-resonant dilepton pair (electrons and muons), which is sensitive to the processes of Fig. 3. Section 9 presents interpretations of these searches and Sect. 10 a summary.

## 2 Detector, trigger, and physics object selection

The central feature of the CMS apparatus is a superconducting solenoid, of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the field volume are a silicon pixel and strip tracker, a crystal electromagnetic calorimeter, and a brass-scintillator hadron calorimeter. Muons are measured with gas-ionization detectors embedded in the steel flux-return yoke of the solenoid. A detailed description can be found in Ref. [26].

The origin of the coordinate system is the nominal interaction point. The \( x \) axis points to the center of the LHC ring and the \( y \) axis vertically upwards. The \( z \) axis lies in the direction of the counterclockwise proton beam. The polar angle \( \theta \) is measured from the positive \( z \) axis, and the azimuthal angle \( \phi \) (in radians) is measured in the \( x-y \) plane. The pseudorapidity \( \eta \) is defined by \( \eta = -\ln[\tan(\theta/2)] \).

Events from pp interactions must satisfy the requirements of a two-level trigger system. The first level performs a fast selection of physics objects (jets, muons, electrons, and photons) above certain thresholds. The second level performs a full event reconstruction. The principal trigger used for the searches with two or more leptons is a dilepton trigger. It requires at least one electron or muon with transverse momentum \( p_T > 17 \text{ GeV} \) and another with \( p_T > 8 \text{ GeV} \). The trigger used for the single-lepton final state requires a single electron (muon) with \( p_T > 27 \text{ (24) GeV} \). All leptons must satisfy \( |\eta| < 2.4 \).

Simulated event samples are used to study the characteristics of signal and standard model (SM) background processes, using the CTEQ6L1 [27] parton distribution functions. The main backgrounds are from top-quark pair (\( t\bar{t} \)), diboson, \( Z + \) jets, and \( W + \) jets processes, depending on the channel considered. Most of the simulated SM background samples are produced with the MADGRAPH 5.1.5.4 [28] event generator, with parton showering and hadronization performed with the PYTHIA 6.4.26 [29] program. We use the most accurate calculations of the cross sections available, generally with next-to-leading-order (NLO) accuracy [30–32]. The detector response is modeled with the GEANT4 [33] library, followed by the same event reconstruction as used for data.

Signal samples are generated with the MADGRAPH 5.1.5.4 generator including up to two additional partons at the matrix element level. Parton showering, hadronization, and the decay of particles, including SUSY particles, are described with the PYTHIA 6.4.26 [29] program. Signal cross sections are calculated at NLO+NLL using the RESUMMIO [34–36] calculation, where NLL refers to the next-to-leading-logarithmic precision. For the SUSY samples with a Higgs boson (H) in the final state, a mass of \( m_H = 126 \text{ GeV} \) [37] is assumed, along with SM branching fractions. Here the H particle indicates the lightest neutral CP-even SUSY Higgs boson, which is expected to have SM-like properties if the other SUSY Higgs bosons are much heavier [22]. To reduce computational requirements, the simulation of detector response for signal samples is based on the CMS fast simulation program [38] in place of GEANT4.

Events are reconstructed using the particle-flow (PF) algorithm [39,40], which provides a self-consistent global assignment of momenta and energies to the physics objects. Details of the reconstruction and identification procedures for electrons, muons, and photons are given in Refs. [41–43]. Lepton (\( e, \mu \)) candidates are required to be consistent with the primary event vertex, defined as the vertex with the largest value of \( \Sigma(p_T^{\text{track}})^2 \), where the summation includes all tracks associated to a given vertex. In the searches with two or more leptons, events with an opposite-sign \( ee, \mu\mu, \) or \( e\mu \) pair with an invariant mass below 12 GeV are rejected in order to exclude quarkonia resonances, photon conversions, and low-mass continuum events. To reduce contamination due to leptons from heavy-flavor decay or misidentified hadrons in jets, leptons are required to be isolated and to have a transverse impact parameter with respect to the primary vertex satisfying \( d_0 < 0.2 \text{ mm} \). Electron and muon candidates are considered isolated if the ratio \( I_{\text{rel}} \) of the scalar sum of the transverse momenta of charged hadrons, photons, and neutral hadrons in a cone of \( \Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} = 0.3 \) around the candidate, divided by the lepton \( p_T \) value, is less than 0.15. The requirements on the \( d_0 \) and \( I_{\text{rel}} \) variables are more stringent in the searches utilizing same-sign dileptons and are described in Sect. 5.
The “hadrons-plus-strips” algorithm [44], which combines PF photon and electron candidates to form neutral pions, and then the neutral pions with charged hadrons, is used to identify hadronically decaying τ-lepton candidates ($τ_0$).

Jets are reconstructed with the anti-$k_T$ clustering algorithm [45] with a distance parameter of 0.5. We apply $p_T$- and $η$-dependent corrections to account for residual effects of non-uniform detector response [46]. A correction to account for multiple pp collisions within the same or a nearby bunch crossing (pileup interactions) is estimated on an event-by-event basis using the jet-area method described in Ref. [47], and is subtracted from the reconstructed jet $p_T$. We reject jets that are consistent with anomalous noise in the calorimeters [48]. Jets must satisfy $|η| < 2.5$ and $p_T > 30$ GeV and be separated by $ΔR > 0.4$ from lepton candidates. The searches presented below make use of the missing transverse energy $E_T^{miss}$, where $E_T^{miss}$ is defined as the modulus of the vector sum of the transverse momenta of all PF objects. The $E_T^{miss}$ vector is the negative of that same vector sum. Similarly, some of the searches use the quantity $H_T$, defined as the scalar sum of jet $p_T$ values.

Most signal topologies considered do not have jets from bottom quarks (“b jets”); for these topologies, events containing b jets are rejected to reduce the background from tכ production. Jets originating from b quarks are identified using the combined secondary vertex algorithm (CSV) [49]. Unless otherwise stated, we use the “medium” working point, denoted CSVM, which has an average b-jet tagging efficiency of 70 %, light-quark jet misidentification rate of 1.5 %, and c-quark jet misidentification rate of 20 % for jets with a $p_T$ value greater than 60 GeV. Corrections are applied to simulated samples to match the expected efficiencies and misidentification rates measured in data. With the exception of the searches described in Sects. 5 and 7, the searches reject events containing CSVM-identified b jets with $p_T > 30$ GeV.

3 Search in the three-lepton final state

Three-lepton channels have sensitivity to models with signatures like those shown in Figs. 1 and 2. For the three-lepton search, we use reconstructed electrons, muons, and $τ_0$ leptons, all within $|η| < 2.4$, requiring that there be exactly three leptons in an event. There must be at least one electron or muon with $p_T > 20$ GeV. Other electrons or muons must have $p_T > 10$ GeV. At most one $τ_0$ candidate is allowed and it must have $p_T > 20$ GeV. Events with multiple $τ_0$ leptons have large backgrounds and are not considered in the present analysis. The principal backgrounds are from WZ diboson production with three genuine isolated leptons that are “prompt” (created at the primary vertex), and from tכ production with two genuine prompt leptons and a third non-prompt lepton that is misclassified as prompt.

Events are required to have $E_T^{miss} > 50$ GeV. We consider events both with and without an opposite-sign-same-flavor (OSSF) electron or muon pair. Events with an OSSF pair are characterized by the invariant mass $M_{ℓℓ}$ of the pair and by the transverse mass $M_T ≡ \sqrt{2E_T^{miss}p_T[1-\cos(Δφ)]}$ formed from the $E_T^{miss}$ vector, the transverse momentum $p_T$ of the remaining lepton, and the corresponding difference $Δφ$ in azimuthal angle. For the three-muon and three-electron events, the OSSF pair with $M_{ℓℓ}$ closer to the Z mass is used. For events without an OSSF pair, which might arise from events with a $Z → ττ$ decay, $M_{ℓℓ}$ is calculated by combining opposite-sign leptons and choosing the pair closest to the corresponding mean dilepton mass determined from $Z → ττ$ simulation (50 GeV for an $eμ$ pair, and 60 GeV for a $ττμ$ or $ττe$ pair).

Events are examined in exclusive search regions (“bins”) based on their values of $M_{ℓℓ}$, $E_T^{miss}$, and $M_T$, as presented below. The $M_{ℓℓ}$ regions for OSSF dilepton pairs are $M_{ℓℓ} < 75$ GeV (“below-Z”), $75 < M_{ℓℓ} < 105$ GeV (“on-Z”), and $M_{ℓℓ} > 105$ GeV (“above-Z”). Further event classification is in $E_T^{miss}$ bins of 50–100, 100–150, 150–200, and >200 GeV. Finally, the $M_T$ regions are <120, 120–160, and >160 GeV.

3.1 Background estimation

The main backgrounds in this search are due to WZ and tכ production, while the background from events with Z + jets and Drell–Yan production is strongly suppressed by the requirement on $E_T^{miss}$. The evaluation of these backgrounds is described in Sects. 3.1.1 and 3.1.2. Less important backgrounds from ZZ production and from rare SM processes such as tTZ, tW, tHW, and triboson production are estimated from simulation using leading-order (LO) generators and are normalized to the NLO production cross sections [50–52]. A 50 % systematic uncertainty is assigned to these backgrounds to account both for the theoretical uncertainty of the cross section calculation and for the differences of the ratio between the LO and NLO cross sections as a function of various physical observables [50].

The systematic uncertainty for backgrounds determined using data control samples is estimated from the difference between the predicted and genuine yields when the methods are applied to simulation.

3.1.1 Background due to WZ production

The three-lepton analysis relies on the $E_T^{miss}$ and $M_T$ variables to discriminate between signal and background. The largest background is from WZ production. For our previous study [18], based on the CMS data collected in 2011,
we calibrated the hadronic recoil of the WZ system using a generalization of the Z-recoil method discussed in Ref. [53]. This calibration led to corrections to the $E_{\text{T}}^{\text{miss}}$ and $M_{T}$ distributions in simulated WZ events. For the data collected in 2012, the rate of pileup interactions increased. We therefore developed a second method, described below, designed to specifically account for jet activity and pileup. The two methods yield consistent results and have similar systematic uncertainties; hence we use the average prediction as our WZ background estimate.

In the new method, we subdivide the $E_{\text{T}}^{\text{miss}}$ distribution in a $Z + \text{jets}$ sample as a function of $H_{T}$ and of the number of reconstructed vertices in the event. A large number of vertices corresponds to large pileup, which causes extraneous reconstruction of energy, degrading the $E_{\text{T}}^{\text{miss}}$ resolution. Larger $H_{T}$ implies greater jet activity, which degrades the $E_{\text{T}}^{\text{miss}}$ resolution as a consequence of the possible jet energy mismeasurement.

In a given two-dimensional bin of the number of reconstructed vertices and $H_{T}$, the x and y components of $E_{\text{T}}^{\text{miss}}$ are found to be approximately Gaussian. Therefore the $E_{\text{T}}^{\text{miss}}$ distribution is expected to follow the Rayleigh distribution, given by:

$$p(E_{\text{T}}^{\text{miss}}) = \sum_{ij} W_{ij} \frac{E_{\text{T}}^{\text{miss}}}{\sigma_{ij}^{2}} e^{-\left(\frac{E_{\text{T}}^{\text{miss}}}{\sigma_{ij}^{2}}\right)^{2}/2\sigma_{ij}^{2}},$$

where $i$ represents the number of vertices in the event, $j$ is the $H_{T}$ bin number, $W_{ij}$ is the fraction of events in the bin, and $\sigma_{ij}$ characterizes the $E_{\text{T}}^{\text{miss}}$ resolution. We then adjust the $\sigma_{ij}$ terms in simulation to match those found in data. The magnitude of the correction varies from a few percent to as high as 30%. To evaluate a systematic uncertainty for this procedure, we vary the level of $E_{\text{T}}^{\text{miss}}$ smearing and determine the migration between different $E_{\text{T}}^{\text{miss}}$ and $M_{T}$ bins in the simulated WZ sample. We find the uncertainty of the WZ background to be 20–35 %, depending on the search region. The final WZ estimate is obtained by normalizing the corrected $E_{\text{T}}^{\text{miss}}$ and $M_{T}$ shape to the theoretical cross section. The theoretical cross section is used to evaluate the SM background from WZ events because the contributions of signal events to WZ data control samples are expected to be significant.

### 3.1.2 Background due to non-prompt leptons

Non-prompt lepton backgrounds arise from $Z + \text{jets}$, Drell–Yan, $t\bar{t}$, and WW + jets events that have two genuine isolated prompt leptons. The third lepton can be a non-prompt lepton from a heavy-flavor decay that is classified as being prompt, or a hadron from a jet that is misidentified as a lepton. This background is estimated using auxiliary data samples. The probability for a non-prompt lepton to satisfy the isolation requirement ($I_{\text{rel}} < 0.15$) is measured in a data sample enriched with dijet events, and varies as a function of lepton $p_{T}$. Alternatively, the isolation probability is studied using $Z$-boson and $t\bar{t}$-enriched data samples. These probabilities, applied to the three-lepton events with the isolation requirement on one of the leptons inverted, are used to estimate background due to such non-prompt leptons. We average the results of the two methods taking into account the precision of each method and the correlations between the individual inputs.

### 3.1.3 Background due to internal conversions

Another background, estimated from data, is due to events with a Z boson and an initial- or final-state photon in which the photon undergoes an asymmetric internal conversion, leading to a reconstructed three-lepton state [13]. To address this background, we measure the rates of $Z \rightarrow e^{+}e^{-}\gamma$ and $Z \rightarrow \nu\bar{\nu}^{'}e^{+}\nu_{e}^{'}$ events in an off-peak control region defined by $|M_{ll} - M_{Z}| > 15$ GeV and $E_{\text{T}}^{\text{miss}} < 50$ GeV. The background estimate is obtained by multiplying the ratio of these rates by the measured rate of events with two leptons and a photon in the search regions. Note that external conversions are strongly suppressed by our electron selection requirements.

### 3.2 Three-lepton search results

Figure 4 shows the distribution of $M_{T}$ versus $M_{ll}$ for data events with an $ee$ or $\mu\mu$ OSSF dilepton pair, where the third lepton is either an electron or muon. The dashed lines delineate nine two-dimensional search regions in the $M_{T}$–$M_{ll}$ plane. The corresponding $E_{\text{T}}^{\text{miss}}$ distributions are shown in comparison to the SM expectations in Fig. 5. Table 1 lists the results.
Fig. 5 $E_T^{\text{miss}}$ distributions, in bins of $M_T$ and $M_{\ell\ell}$, for three-lepton events with an ee or $\mu\mu$ OSSF dilepton pair, where the third lepton is either an electron or a muon. The SM expectations are also shown. The $E_T^{\text{miss}}$ distributions for example signal scenarios are overlaid. The first (second) number in parentheses indicates the value of $m_{\tilde{\chi}}$ ($m_{\tilde{\chi}^0_1}$)

Table 1 Observed yields and SM expectations for three-lepton events with an ee or $\mu\mu$ OSSF pair, where the third lepton is either an electron or muon. The uncertainties include both the statistical and systematic components

as a function of $E_T^{\text{miss}}$, $M_T$, and $M_{ll}$. The data are broadly consistent with SM expectations. In the search regions with $M_T > 160$ GeV and an on-Z OSSF dilepton pair, and in the search region with $M_T > 160$ GeV, $50 < E_T^{\text{miss}} < 100$ GeV, and a below-Z OSSF pair, the data exceed the expected background with a local significance at the level of approximately two standard deviations.

The corresponding results for $ee\mu$ and $e\mu\mu$ events without an OSSF pair, for events with a same-sign $ee$, $e\mu$, or $\mu\mu$ pair and one $\tau_h$ candidate, and for events with an opposite-sign $e\mu$ pair and one $\tau_h$ candidate, are presented in Appendix A. The different leptonic content in these search channels provides sensitivity to various classes of SUSY models (Sect. 9).

4 Search in the four-lepton final state

As mentioned in the introduction, we interpret our four-lepton final state results in the context of a GMSB model, in combination with results from a study with two leptons and at least two jets, which is presented in Sect. 6. This situation motivates the use of four-lepton channels with at least one OSSF pair that is consistent with a Z boson decay. The data are binned in intervals of $E_T^{\text{miss}}$ in order to discriminate between signal and background.

We use the same object selection as for the three-lepton final state, requiring exactly four leptons (electrons, muons, and at most one $\tau_h$ candidate). We require that there be an $ee$ or $\mu\mu$ OSSF pair with an invariant mass within 15 GeV of the nominal Z boson mass. The background determination methods are also the same as described for the three-lepton final state. The main background, from $ZZ$ production, is thus estimated from simulation, with corrections applied to the predicted $E_T^{\text{miss}}$ spectrum as described in Sect. 3.1.1. Backgrounds from hadrons that are misreconstructed as leptons or from non-prompt leptons are evaluated using control samples in the data as described in Sect. 3.1.2.

Table 2 summarizes the results. We consider events with exactly one OSSF pair and no $\tau_h$ candidate, with exactly one OSSF pair and one $\tau_h$ candidate, and with exactly two OSSF pairs and no $\tau_h$ candidate. The distribution of $E_T^{\text{miss}}$ versus $M_{ll}$ for events without a $\tau_h$ candidate is presented in Fig. 26 of Appendix A.

5 Search in the same-sign two-lepton final state

Three-lepton final states are not sensitive to the chargino–neutralino pair production processes of Fig. 1 if one of the leptons is unidentified, not isolated, or outside the acceptance of the analysis. For small mass differences between the SUSY particle states in Fig. 1, one of the leptons might be too soft to be included in the analysis. Some of these otherwise-rejected events can be recovered by requiring only two leptons. These leptons should have the same sign (SS) to suppress the overwhelming background from opposite-sign lepton pairs.

We therefore perform a search for events with an SS lepton pair, using the selection and methodology presented in Ref. [17]. We require events to contain exactly one SS $ee$, $e\mu$, or $\mu\mu$ pair, where the $e$ and $\mu$ candidates must satisfy $p_T > 20$ GeV and $|\eta| < 2.4$. To better reject background from fake leptons, we tighten the $e$ ($\mu$) isolation requirement to $I_{\text{rel}} < 0.09$ (0.10) and the $d_0$ requirement to 0.1 (0.05) mm.

Background from processes such as $WZ$ and $t\bar{t}Z$ production is reduced by requiring $E_T^{\text{miss}} > 120$ GeV. This background is further reduced by rejecting events that, after applying looser $e$ and $\mu$ selection criteria, contain an OSSF pair within 15 GeV of the $Z$ boson mass.

We evaluate the background from $WZ$ events using simulated events and assign a 15 % systematic uncertainty, which accounts for the difference between the observed and simulated yields in a $WZ$-event-enriched data control sample obtained by inverting the $Z$-boson veto. A second background is from events containing a prompt lepton from a $W$ boson decay and a genuine lepton of the same sign from heavy-flavor decay or a misidentified hadron (mainly from $b$-events). We evaluate this background by determining the probability for a loosely identified electron or muon to satisfy the selection criteria in a background-enriched control region [17]. We assign a 50 % systematic uncertainty to this background based on the difference in sample com-

position between the control regions used to measure this probability and the signal regions. A third background is from events with two opposite-sign leptons, in which one of the leptons is an electron with an incorrect charge assignment caused by severe bremsstrahlung. To evaluate this background, we select opposite-sign events that satisfy the selection, weighted by the probability of electron-charge misassignment, determined using $Z \to ee$ events. Finally, background from rare SM processes, such as those described in Sect. 3.1, is estimated from simulation and assigned an uncertainty of 50%.

Two search regions are defined, one by $E_T^{\text{miss}} > 200$ GeV, and the other by $120 < E_T^{\text{miss}} < 200$ GeV and $N_{\text{jets}} = 0$, where $N_{\text{jets}}$ for this purpose denotes the number of jets with $p_T > 40$ GeV and $|\eta| < 2.5$. The jet veto enhances the sensitivity to the signal models targeted here by suppressing backgrounds with large hadronic activity, such as $t\bar{t}$ events.

The observed yields and corresponding SM expectations are given in Table 3. Results are presented both with and without the veto of events with a third selected lepton. The distribution of $E_T^{\text{miss}}$ in comparison with the SM expectation is shown in Fig. 6, along with the observations and expectations in each search region. The interpretation, presented in Sect. 9, is based on the two signal regions defined above, and includes the third lepton veto in order to simplify combination with the results of the three-lepton search.

### 6 Search in the $WZ/ZZ + E_T^{\text{miss}}$ final state with two leptons and two jets

The three- and four-lepton searches described above are sensitive not only to the processes of Fig. 1, but also to those of Fig. 2, with on-shell or off-shell vector bosons. In this section, we describe a search for events with two leptons consistent with a $Z$ boson and at least two jets ($Z+\text{dijet}$), which extends the sensitivity to some of the processes of Fig. 2. Specifically, we select events in which an on-shell $Z$ boson decays to either an $e^+e^-$ or $\mu^+\mu^-$ pair, while an on-shell $W$ boson or another on-shell $Z$ boson decays to two jets. The object selection and background determination procedures are based on those presented in Ref. [9]: both leptons must have $p_T > 20$ GeV and the dilepton invariant mass must be consistent with the $Z$ boson mass to within 10 GeV. At least two jets with $p_T > 30$ GeV are required. Events with a third lepton are rejected in order to reduce the background from $WZ$ production.

Following the lepton and jet selection, the dominant background is from $Z+\text{jets}$ events. This background is strongly suppressed by requiring large values of $E_T^{\text{miss}}$, leaving $t\bar{t}$ production as the dominant background. The $t\bar{t}$ background is reduced by a factor of ~10 by applying the veto on events with b jets mentioned in Sect. 2. Background from $t\bar{t}$ and $Z+\text{jets}$ events is reduced further by requiring the dijet mass $M_{jj}$ formed from the two highest $p_T$ jets to be consistent with a W or Z boson, namely $70 < M_{jj} < 110$ GeV.

For the remaining background from $Z+\text{jets}$ events, significant $E_T^{\text{miss}}$ arises primarily because of the mismeasurement of jet $p_T$. We evaluate this background using a sample of $\gamma+\text{jets}$ events as described in Ref. [9], accounting for the different kinematic properties of the events in the control and signal samples.

The remaining background other than that from $Z+\text{jets}$ events is dominated by $t\bar{t}$ production, but includes events with $WW$, single-top-quark, and $\tau\tau$ production. This background is characterized by equal rates of $ee+\mu\mu$ versus $e\mu$ events and so is denoted "flavor symmetric" (FS). To evaluate the FS background, we use an $e\mu$ control sample, and correct for the different electron vs. muon selection efficiencies. The SM backgrounds from events with $WZ$ and $ZZ$ production are estimated from simulation and assigned uncertainties based on comparisons with data in control samples with exactly three leptons ($WZ$ control sample) and exactly four leptons ($ZZ$ control sample), and at least two jets. Background from rare SM processes with $t\bar{t}Z$, $ZZZ$, $ZZW$, and $ZWW$ production is determined from simulation with an assigned uncertainty of 50%. The background estimation methodology is validated in a signal-depleted control region, defined by $M_{jj} > 110$ GeV, which is orthogonal to the search.

Table 3 Observed yields and SM expectations for the same-sign dilepton search, with and without a veto on the presence of a third lepton. The uncertainties include both the statistical and systematic components. The $N_{\text{jets}}$ variable refers to the number of jets with $p_T > 40$ GeV and $|\eta| < 2.5$.

| Sample            | $E_T^{\text{miss}} > 200$ GeV | $E_T^{\text{miss}} > 200$ GeV, $N_{\text{jets}} = 0$ | $E_T^{\text{miss}} > 200$ GeV, 3rd lepton veto | $E_T^{\text{miss}} > 200$ GeV, $N_{\text{jets}} = 0$, 3rd lepton veto |

Fig. 6 $E_T^{miss}$ distribution for same-sign dilepton candidates in comparison with the SM expectations (top). The bottom panel shows the ratio and corresponding uncertainty of the observed and total SM expected distributions. The third lepton veto is not applied. The distributions of example signal scenarios are overlaid. Observed yields and expected backgrounds for the different search regions (bottom). In both plots, events with $E_T^{miss} > 120$ GeV are displayed, and the hashed band shows the combined statistical and systematic uncertainties of the total background.

The results are presented in Table 4. The five exclusive intervals with $E_T^{miss} > 80$ GeV are treated as signal regions in the interpretations presented in Sect. 9. Figure 7 displays the observed $E_T^{miss}$ and dilepton mass distributions compared with the sum of the expected backgrounds.

7 Searches in the WH + $E_T^{miss}$ final state

The recent observation of a Higgs boson [54–56] offers the novel possibility to perform beyond-the-SM searches by exploiting the measured properties of this particle. In particular, the heavy neutralinos are expected to decay predominantly via a Higgs boson in large regions of SUSY parameter space, and in this section we report searches for such decays.

Three exclusive final states sensitive to the process of Fig. 2 (center) are considered here. In all searches, the W boson is required to decay leptonically. A search in the single-lepton final state provides sensitivity to events in which the Higgs boson decays to a $b\bar{b}$ pair. A search in the same-sign dilepton final state targets events with the decay $H \rightarrow W^+W^-$ in which one of the W bosons decays leptonically and the other hadronically. The results of the CMS inclusive multilepton search [57] are reinterpreted, covering final states with at least three leptons. It is used to target the decays $H \rightarrow W^+W^-$, $H \rightarrow ZZ$, and $H \rightarrow \tau^+\tau^-$, where the W and Z bosons, and the $\tau$ lepton, decay leptonically. The results from these searches are combined to place limits on the production of the WH + $E_T^{miss}$ final state.

7.1 Search in the single-lepton final state

7.1.1 Overview of the search

In this section we report the results from a search for $\tilde{\chi}_1^\pm \tilde{\chi}_0^0 \rightarrow (W^{\pm}H^0) \rightarrow \ell\nu b\bar{b} + E_T^{miss}$ events. Previous searches involving the $H \rightarrow b\bar{b}$ decay mode, corresponding to the largest SM branching fraction (56 %) [58], have targeted the associated production with a leptonically decaying W boson [59]. In the present search, we impose additional kinematic requirements on $E_T^{miss}$ and related quantities. These requirements strongly suppress both the SM backgrounds and the SM production of a Higgs boson while retaining efficiency for the SUSY signal. This search is an extension of a search for direct top-squark pair production [14], which targets events with a single lepton, at least four jets, and $E_T^{miss}$, with similar object selection and analysis methodology. The final state considered here is similar, except that we expect only two jets.

Events are required to contain a single lepton, exactly two $b$ jets, and $E_T^{miss}$. The largest background arises from $t\bar{t}$ production, due both to semileptonic $t\bar{t}$ events and to events where both top quarks decay leptonically but one lepton is not
Table 4 Observed yields and SM expectations, in bins of $E_T^{\text{miss}}$, for the Z + dijet analysis. The total background is the sum of the Z + jets background, the flavor-symmetric (FS) background, and the WZ, ZZ, and rare SM backgrounds. All uncertainties include both the statistical and systematic components. The expected yields for the WZ + $E_T^{\text{miss}}$ model with $m_\chi = 300$ GeV and $m_{\tilde{\chi}_1^0} = 0$ GeV, and the GMSB ZZ + $E_T^{\text{miss}}$ model with $\mu = 320$ GeV (see Sect. 9.3) are also indicated.

Events with W + jets production also constitute an important source of background. The SM backgrounds are suppressed using several kinematic requirements based on large values of $E_T^{\text{miss}}$. Signal regions are defined by successively tighter requirements on $E_T^{\text{miss}}$. The signal is expected to produce a peak in the dijet mass spectrum at $M_{bb'} = m_H$.

7.1.2 Event selection

Events are required to contain exactly one electron (muon) with $p_T > 30$ (25) GeV and $|\eta| < 1.4442$ (2.1). Electrons are restricted to the central region of the detector for consistency with the search for top-squarks [14]. There must be exactly two jets with $|\eta| < 2.4$ and no jets with $2.4 < |\eta| < 4.7$. This latter requirement substantially reduces the $t\bar{t} \rightarrow \ell +$ jets background, which typically has four jets. The two selected jets must satisfy the CSV b-tagging criteria and have $p_T > 30$ GeV. We require $M_T > 100$ GeV, which primarily rejects backgrounds with a single W $\rightarrow \ell +$ jets decay and no additional $E_T^{\text{miss}}$, such as $t\bar{t} \rightarrow \ell +$ jets, W + jets, and SM WH $\rightarrow \ell \nu b\bar{b}$ events, and single-top-quark events in the $t$ and $s$ channels. To suppress the dilepton $t\bar{t}$ backgrounds, events with an isolated high-$p_T$ track or $\tau_t$ candidate are rejected.

Further suppression of the $t\bar{t}$ backgrounds is achieved by using the $M_T^{bl}$ variable [60], which is defined as the minimum “mother” particle mass compatible with the four-momentum of the lepton, b-tagged jets, and $E_T^{\text{miss}}$. It has an endpoint at the top-quark mass for $t\bar{t}$ events without mismeasurement effects, while signal events may have larger values. We require $M_T^{bl} > 200$ GeV.

The dijet mass $M_{bb'}$ formed from the two selected jets is required to satisfy $100 < M_{bb'} < 150$ GeV. This requirement has an efficiency of about 80% for signal events.

7.1.3 Backgrounds and their estimation methodology

Backgrounds are grouped into six categories. The largest background arises from $t\bar{t}$ events and from single-top-quark production in the tW channel, in which both W bosons decay leptonically (dilepton top-quark background). Backgrounds from $t\bar{t}$ and single-top-quark production with one leptonically decaying W boson are referred to as the single-lepton top-quark background. Backgrounds from WZ production, where the W boson decays leptonically and the Z boson decays to a b$\bar{b}$ pair, are referred to as the $W \rightarrow \ell \nu b\bar{b}$ background. Backgrounds from W bosons produced in associated production with a b$\bar{b}$ pair are referred to as the $W + b\bar{b}$ back-
ground, while production of W bosons with other partons constitutes the W + light-flavor jets background. Finally, the “rare background” category consists of processes with two top quarks and a W, Z or Higgs boson, as well as diboson, triboson, Z + jets, and SM WH \( \rightarrow \ell \nu b \bar{b} \) events. The Z + jets process has a large cross section but is included in the rare background category because its contribution is very small after the signal-region requirements are imposed. With the exception of the W + light-flavor jets background, the background estimation is based on simulation.

The simulation is validated in three data control regions (CR) that are enriched in different background components.

A data sample enriched in W + light-flavor jets is obtained by vetoing events with b-tagged jets (CR-0b). A data sample enriched in the dilepton top-quark background is obtained by requiring either exactly two leptons satisfying the lepton selection criteria, or one such lepton and an isolated high-\( p_T \) track (CR-2\( \ell \)). Finally, the \( M_{b\bar{b}} \) requirement is inverted to obtain a data sample (CR-\( M_{b\bar{b}} \)) consisting of a mixture of backgrounds with similar composition as the signal region.

7.1.4 Results

Four overlapping signal regions are defined by the requirements \( E_T^{\text{miss}} > 100, 125, 150, \) and 175 GeV. In general, signal regions with tighter \( E_T^{\text{miss}} \) requirements are more sensitive to signal scenarios with larger mass differences \( m_Z - m_{\tilde{\chi}^0_1} \). The results for these signal regions are summarized in Table 5. The data are seen to agree with the background predictions to within the uncertainties. The expected yields for several signal scenarios are indicated, including systematic uncertainties that are discussed in Sect. 9. The distributions of \( M_{b\bar{b}} \) are displayed in Fig. 8. No evidence for a peak at \( M_{b\bar{b}} = m_H \) is observed.

7.2 Search in the same-sign dilepton final state

The object selection and background estimation methodology for the SS dilepton search follow those presented in Sect. 5. We define the quantity \( M_{\ell\bar{\ell}} \) as the three-body invariant mass of the system obtained by combining the two highest \( p_T \) jets in an event with the lepton closest to the dijet axis. Signal events peak below \( m_H \), due to the undetected neutrino, as shown in Fig. 9. Background events generally have larger values of \( M_{\ell\bar{\ell}} \). Events are required to satisfy \( M_{\ell\bar{\ell}} < 120 \text{ GeV} \).

Fig. 7 Distributions for Z + dijet events in comparison with SM expectations: (top) \( E_T^{\text{miss}} \) distribution for events with the dilepton invariant mass satisfying \( 81 < M_{\ell\ell} < 101 \) GeV; expected results for two signal scenarios are overlaid. (bottom) \( M_{b\bar{b}} \) distribution for \( E_T^{\text{miss}} > 80 \) GeV. The ratio of the observed to predicted yields in each bin is shown in the lower panels. The error bars indicate the statistical uncertainties of the data and the shaded band the total background uncertainty.
Table 5 Observed yields and SM expectations, in several bins of $E_T^{\text{miss}}$, for the single-lepton WH + $E_T^{\text{miss}}$ analysis. The expectations from several signal scenarios are shown; the first number indicates $m_{\tilde{\chi}}$ and the second $m_{\tilde{\chi}_2^0}$ (GeV). The uncertainties include both the statistical and systematic components.

| Total background                | 7.7 ± 1.9                     | 5.4 ± 1.3                     | 3.8 ± 1.0                     | 2.3 ± 0.6                     |
| Data                            | 7                             | 6                             | 3                             | 3                             |

We require the presence of exactly two SS leptons (ee, $\mu\mu$, or $e\mu$), each with $p_T > 20$ GeV, and of either exactly two or exactly three jets, each with $p_T > 30$ GeV. The $E_T^{\text{miss}}$ value must exceed 40 GeV. To suppress $t\bar{t}$ background, events with a “tight” CSV b jet or with two or more “loose” CSV b jets are rejected, where the tight (loose) CSV working point

![Fig. 8 Distributions of $M_{E_T}$ for the single-lepton WH + $E_T^{\text{miss}}$ analysis for (upper left) $E_T^{\text{miss}} > 100$ GeV, (upper right) $E_T^{\text{miss}} > 125$ GeV, (lower left) $E_T^{\text{miss}} > 150$ GeV, and (lower right) $E_T^{\text{miss}} > 175$ GeV after all signal region requirements have been applied except for that on $M_{E_T}$. The data are compared to the sum of the expected backgrounds. The labels “2\ell top” and “1\ell top” refer to the dilepton top-quark and single-lepton top-quark backgrounds, respectively. The band indicates the total uncertainty of the background prediction. Results from an example signal scenario are shown, stacked on top of the SM background.
To suppress $t\bar{t}$ events in which the decays of a $W$ boson and a $b$ quark lead to an SS lepton pair, we calculate the quantity $M_{T2}^{J}$ [61], which is the minimum mass of a mother particle compatible with the four-momenta of the two leptons, jets, and $E_{T}^{miss}$. For events with three jets, $M_{T2}^{J}$ is calculated with the two jets that minimize the result. We require $M_{T2}^{J} > 100$ GeV.

The background estimation methodology (Sect. 5) is validated using a signal-depleted data control region defined by inverting the $M_{jj}$ requirement. We observe 51 events in this control region, consistent with the background estimate of $62 \pm 22$ events.

The results are summarized in Table 6. No evidence for a peak in the $M_{jj}$ distribution is observed, as seen from Fig. 9. In the signal region $M_{jj} < 120$ GeV, we observe three events whereas $2.9 \pm 1.2$ SM background events are expected.

### 7.3 Search in the multilepton final state

For the multilepton search presented in Ref. [57], events with at least three leptons are selected, including up to one $\tau_{b}$ candidate. These events are categorized into multiple exclusive signal regions based on the number and flavor of the leptons, the presence or absence of an OSSF pair, the invariant mass of the OSSF pair (if present), the presence or absence of a tagged $b$ jet, and the $E_{T}^{miss}$ and $H_{T}$ values. The most sensitive signal regions for this search are those with exactly three leptons, no tagged $b$ jets (using the CSVM criteria), and a low $H_{T}$ value.

Backgrounds from dilepton $t\bar{t}$ events with non-prompt leptons are evaluated from simulation, while other backgrounds with non-prompt leptons are determined using data control samples. Backgrounds from $WZ$ and $ZZ$ diboson processes are estimated from simulation, with a correction to the $E_{T}^{miss}$ resolution based on comparisons to data in control regions.

### Table 6 Observed yields and SM expectations for the same-sign dilepton $WH + E_{T}^{miss}$ analysis. The expectations from several signal scenarios are shown; the first number indicates $m_{\gamma}$ and the second $m_{Z'}$(GeV). The uncertainties include both the statistical and systematic components

The data yields in the signal regions are found to be consistent with the expected SM backgrounds. The observed data yields, expected SM backgrounds, and expected signal yields for the five most sensitive signal regions for the $m_{\tilde{t}} = 130$ GeV, $m_{\tilde{\chi}_1^0} = 1$ GeV scenario, are shown in Table 7. Additional signal-depleted regions are used to constrain the backgrounds and associated uncertainties. Similar tables for other scenarios are presented in Appendix B.

### 8 Searches in the final state with a non-resonant opposite-sign dilepton pair

Finally, we present a search for events with an oppositely charged $\mu\mu$, $e\mu$, or $\mu\mu$ pair in which the lepton pair is inconsistent with $Z$ boson decay. The search is sensitive to the processes shown in Fig. 3.

Both leptons are required to have $p_T > 20$ GeV. The ee or $\mu\mu$ invariant mass must differ from the $Z$ boson mass by at least 15 GeV. Events must have $E_T^{miss} > 60$ GeV and no tagged b jet defined with the CSVM criteria. The remaining background is mostly composed of events with $t\bar{t}$ and WW production and is reduced using the $M_{CT\perp}$ variable, which is defined in Ref. [62].

The $M_{CT\perp}$ variable is designed to identify events with two boosted massive particles that each decay into a visible particle and an invisible one. For events with two W bosons that each decay leptonically, and for perfect event reconstruction, $M_{CT\perp}$ has an endpoint at the $W$ boson mass. In practice, because of imperfect event reconstruction, background events can appear at larger values of $M_{CT\perp}$. However, for SM events, the distribution of $M_{CT\perp}$ falls rapidly for $M_{CT\perp} > m_W$. In contrast, for the signal scenario, the $M_{CT\perp}$ distribution can extend to much higher values.

The background evaluation for this search is based on templates that describe the shape of the $M_{CT\perp}$ distribution for each of the major background categories. The templates are obtained either from data control samples or simulation. The template shapes are fit to data to determine their respective normalizations. Because backgrounds from $Z$ and ZZ processes contribute predominantly to the ee and $\mu\mu$ final states, separate templates are derived for same-flavor and opposite-flavor events.

A top-quark control sample is selected by inverting the b-jet veto. The corresponding template accounts for backgrounds with $t\bar{t}$ events (with or without accompanying vector bosons) and single-top-quark events produced with W bosons. We verify with simulation that the corresponding $M_{CT\perp}$ template accurately models the shape of the targeted event sample in the signal region.

A template derived from simulation accounts for events with diboson production and for rare events, where by 'rare' we in this case mean events from Higgs and triboson production. The simulation is validated using control regions. A first control region is selected by requiring the dilepton mass to be consistent with the $Z$ boson mass. A second control region is selected by requiring a third isolated electron or muon. The two control regions are dominated by events with ZZ and WZ production, respectively. The $M_{CT\perp}$ distribution is found to be well described by the simulation for both control regions.

The simulation of events with WW production is validated using the three-lepton WZ-dominated control sample. One lepton is removed from the event, and its four-momentum is added to the $E_T^{miss}$ vector. Rescaling the $M_{CT\perp}$ value of each event by $m_W/m_Z$ yields a distribution with very similar properties to events with WW production, as verified with simulation. The number of events in the control sample is small, and we assign a systematic uncertainty to each $M_{CT\perp}$ bin defined by the difference between the yield in the data control sample and the WW event simulation, or else the statistical uncertainty of the data control sample, whichever is larger.

Similarly, a template distribution for backgrounds with two leptons from an off-shell $Z$ boson, with $E_T^{miss}$ from misreconstructed jets, is obtained from simulation. We weight the simulated events such that the $E_T^{miss}$ distribution agrees with data in the on-$Z$ ($|M_{\ell\ell} - M_Z| < 15$ GeV) control region. We then examine the $M_{CT\perp}$ distribution in the $M_{CT\perp} < 100$ GeV, on-$Z$ control region, where this background is expected to dominate, to validate the simulation after all corrections have been applied. We assign a bin-by-bin system-
Table 8 Results from a maximum likelihood fit of the background-only hypothesis to the $M_{\text{CT}}$ distribution in data for $M_{\text{CT}} > 10$ GeV for the non-resonant opposite-sign dilepton analysis. The corresponding results from simulation are also shown.

| Sample               | Opposite flavor | Same flavor | Opposite flavor | Same flavor |
|----------------------|-----------------|-------------|-----------------|-------------|
|                      | Fit             | Simulation  | Fit             | Simulation  |
| Top quark            | 3,750 ± 750     | 3,360       | 2,780 ± 420     | 2,472       |
| Diboson and rare SM  | 1,460 ± 210     | 1,433       | 1,170 ± 180     | 1,211       |
| $Z/\gamma^*$        | 57 ± 50         | 106         | 710 ± 420       | 917         |
| Non-prompt           | <96             | 477         | 710 ± 520       | 156         |

The systematic uncertainty given by the fractional difference between the data and template in this control region (around 25% for each bin).

We construct a template describing backgrounds with a leptonically decaying W boson and a non-prompt lepton from a data control sample, obtained by selecting events with two same-charge leptons, one of which has a relative isolation in a sideband defined by $0.2 < I_{\text{rel}} < 0.3$. All other selection requirements are the same as for the nominal analysis. Due to the small number of events in the control sample, we assign a 30% systematic uncertainty to each bin.

A binned maximum likelihood fit of the $M_{\text{CT}}$ distribution is performed for $M_{\text{CT}} > 10$ GeV in order to determine the normalizations of the templates. The fit assumes the SM-only hypothesis. The fitting procedure is validated using simulation to verify that it behaves as expected both with and without injected signal. The results of the fit are presented in Table 8 and Fig. 10. We use a binned Anderson–Darling test [63] to verify that the fit results are consistent with the SM, finding a $p$ value of 0.41 with respect to SM-only pseudo-experiments.

We can recast the analysis as a comparison of event counts in a high-$M_{\text{CT}}$ signal region. To do this, we use the same templates, but fit the background normalizations in the $10 < M_{\text{CT}} < 120$ GeV region, where signal contributions are expected to be negligible. We then use these fitted normalizations to extrapolate to the $M_{\text{CT}} > 120$ GeV region. Since the $t\bar{t}$ and diboson background shapes are similar in the low-$M_{\text{CT}}$ region, we constrain the ratio of the $t\bar{t}$ to diboson yields to the value obtained from simulation, assigning a 10% uncertainty.

The results are given in Table 9. The sum of the yields from the low- and extrapolated high-$M_{\text{CT}}$ regions agree with the yields in Table 8 to within the uncertainties. Note that the extra constraint on the ratio of the $t\bar{t}$ to diboson yields leads to smaller uncertainties than those in Table 8. The numbers of observed events in the high-$M_{\text{CT}}$ regions are found to be consistent with the background estimates, for both the opposite- and same-flavor channels.

For slepton pair production [Fig. 3 (bottom)], in which only same-flavor lepton pairs are produced, we also consider a more focused approach in which events with opposite-flavor dilepton pairs provide a data control sample. We use the $M_{\text{CT}}$ distribution of the opposite-flavor dilepton events to define a template for the flavor-symmetric background. The flavor-symmetric background includes top-quark and WW events, as well as WZ events in which one selected lepton...

Fig. 10 $M_{\text{CT}}$ distribution for the non-resonant opposite-sign dilepton analysis compared to the background prediction for the (top) opposite-flavor and (bottom) same-flavor channels. The background prediction is based on a fit of templates derived from control samples or simulation. The signal distributions with two different chargino mass values for the SUSY scenario shown in Fig. 1 (top) are also shown, with the LSP mass set to zero. The ratio of the data to the fitted distribution is shown in the lower panels.
Table 9 Results from a maximum likelihood fit of the background-only hypothesis to the $M_{\text{CT,}\perp}$ distribution in data, performed for events with $10 < M_{\text{CT,}\perp} < 120$ GeV and extrapolated to the $M_{\text{CT,}\perp} > 120$ GeV region, for the non-resonant opposite-sign dilepton analysis. Where the predicted value is zero, the one standard deviation upper limit is given

9 Interpretations of the searches

We now present the interpretation of our results in the context of models for the direct electroweak pair production of charginos, neutralinos, and sleptons. We compute 95% confidence level (CL) upper limits on the new-physics cross sections using the CL$_s$ method [64–66], incorporating the uncertainties in the signal efficiency and acceptance described below and the uncertainties of the expected background ($\sigma_{\text{experiment}}$). For each point in the signal parameter space we arrange the search regions according to their expected sensitivity, and compute limits using the results from simultaneous counting experiments in the most sensitive search regions. For the WH search we use the search regions that contribute to 90% of the total signal acceptance. For the other searches, we use the ten most sensitive search regions. The NLO+NLL cross sections from Refs. [34–36] are used to place constraints on the masses of the charginos, neutralinos, and sleptons.
In setting limits, we account for the following sources of systematic uncertainty associated with the signal event acceptance and efficiency. The uncertainty of the integrated luminosity determination is 2.6% [67]. Samples of $Z \to \ell\ell$ events are used to measure the lepton efficiencies, and the corresponding uncertainties (3% per lepton) are propagated to the signal event acceptance and efficiency. The uncertainty of the trigger efficiency is 5% for the dilepton and single-lepton triggers used. The uncertainty of the b-jet tagging efficiency results in an uncertainty for the acceptance that depends on the model details but is typically less than 5%. The energy scale of hadronic jets is known to 1–4%, depending on the model details but is typically less than 5%. The energy scale of hadronic jets is known to 1–4%, depending on the model details but is typically less than 5%. The energy scale of hadronic jets is known to 1–4%, depending on the model details but is typically less than 5%. The energy scale of hadronic jets is known to 1–4%, depending on the model details but is typically less than 5%. The energy scale of hadronic jets is known to 1–4%, depending on the model details but is typically less than 5%.

We first place limits on the production of chargino–neutralino pairs in models with light sleptons, depicted in Fig. 1, using the results of the three-lepton (Sect. 3) and same-sign dilepton (Sect. 5) searches. Three different scenarios are considered, with different assumptions about the nature of the sleptons, which affect the number of $\tau$ leptons in the final state. These interpretations depend on whether the sleptons are the SUSY partners $\tilde{\ell}_L$ or $\tilde{\ell}_R$ of left-handed or right-handed leptons. We consider two limiting cases. In one case, $\tilde{\ell}_R$ does not participate while $\tilde{\ell}_L$ and $\tilde{\nu}$ do: then both diagrams of Fig. 1 exist, and the chargino and neutralino decay to all three lepton flavors with equal probability. Furthermore, two additional diagrams in which the decay $\tilde{\chi}^0_1 \to \ell \ell \tilde{\nu}$ is replaced by $\tilde{\chi}^0_2 \to \tilde{\nu} \nu$ reduce the fraction of three-lepton final states by 50%. In the second case, in which $\tilde{\ell}_R$ participates while $\tilde{\ell}_L$ and $\tilde{\nu}$ do not, only the diagram of Fig. 1 (bottom) exists, and there is no reduction in the three-lepton final states. Because the $\tilde{\ell}_R$ couples to the chargino via its higgsino component, chargino decays to $\tilde{\ell}_R$ strongly favor production of a $\tau$ lepton. We thus consider three flavor scenarios:

- the “flavor-democratic” scenario: the chargino ($\tilde{\chi}^+_1$) and neutralino ($\tilde{\chi}^0_1$) both decay with equal probability into all three lepton flavors, as expected for $\tilde{\ell}_L$;
- the “$\tau$-enriched” scenario: the chargino decays exclusively to a $\tau$ lepton as expected for $\tilde{\ell}_R$, while the neutralino decays democratically;
- the “$\tau$-dominated” scenario: the chargino and neutralino both decay only to $\tau$ leptons.

Figure 12 displays the results of the three-lepton search in the flavor-democratic signal model with slepton mass parameter $x_T = 0.5$. The shading in the $m_{\tilde{\chi}^0_1}$ versus $m_{\tilde{\chi}^0_2} (= m_{\tilde{\tau}^\pm})$ plane indicates the 95% CL upper limit on the chargino–neutralino production cross section times branching fraction. The contours bound the mass regions excluded at 95% CL assuming the NLO+NLL cross sections for a branching fraction of 50%, as appropriate for the visible decay products in this scenario. The observed, median expected, and ±1σ expected bounds are shown.

9.1 Limits on chargino–neutralino production with slepton-mediated decays

The corresponding results for the combination of the SS dilepton and three-lepton searches are shown in Fig. 13 for two values of $x_T$ (0.05 and 0.95).

Figure 14 presents the corresponding limits for the $\tau$-enriched scenario and Fig. 15 for the $\tau$-dominated scenario. For the $x_T = 0.50$ scenario, all three leptons are produced with significant values of $p_T$. As a consequence, the trilepton analysis is more sensitive than the SS dilepton search, for which the limit contours are omitted in Figs. 12, 14 (cen-
We next place limits on chargino–neutralino production without light sleptons.

For the models with $\chi_T^0 = 0.05$ [Figs. 13 (top), 14 (top)], the decay $\tilde{\tau} \rightarrow \tau \chi_1^0$ is not kinematically allowed for signal scenarios with $m_{\chi_1^0} - m_{\chi_1^+} < 20 m_\tau$. Therefore, in this region, the decay $\chi_1^0 \rightarrow \tau \nu_\tau$ is suppressed. Similarly, in the models with $\chi_T^0 = 0.95$ [Figs. 13 (bottom), 14 (bottom)], the decay $\chi_2^0 \rightarrow \tau \nu_\tau$ is not kinematically allowed in the region with $m_{\chi_2^0} - m_{\chi_1^0} < 20 m_\tau$.

9.2 Limits on chargino–neutralino production without light sleptons

We next place limits on chargino–neutralino production under the assumption that the sleptons are too heavy to participate, as depicted in Fig. 2. The chargino is assumed to always decay to a W boson and the $\chi_1^0$ LSP. The $\chi_2^0$ is expected to decay to a $\chi_1^0$ LSP and either a Z boson or the Higgs boson.
The relative branching fraction ($B$) for these two decays is in general model-dependent [69]. We thus consider two limiting cases, in which either $B(\tilde{\chi}_1^0 \rightarrow Z\tilde{\chi}_1^0) = 1$ (Sect. 9.2.1), or $B(\tilde{\chi}_2^0 \rightarrow H\tilde{\chi}_1^0) = 1$ (Sect. 9.2.2). The sensitivity in a generic model lies between these two extremes.

9.2.1 Limits on chargino–neutralino production in the $WZ + E_T^{\text{miss}}$ final state

To evaluate upper limits on the process of Fig. 2 (top), we use the results of the $WZ/ZZ + E_T^{\text{miss}}$ analysis (Sect. 6) together with the three-lepton analysis (Sect. 3). Figure 16 (top) displays the observed limits for the individual studies and their combination. The sensitivities of the three-lepton and $WZ/ZZ + E_T^{\text{miss}}$ analyses are complementary, with the three-lepton results dominating the sensitivity in the region where the difference between the neutralino masses is small, and the $WZ/ZZ + E_T^{\text{miss}}$ results dominating the sensitivity in the region where $m_{\tilde{\chi}}$ is large. A significant degradation in sensitivity is present in the region of parameter space in which $\Delta M \approx M_Z$, causing the chargino and neutralino decay products to be produced with low momentum in the rest frame of their mother particles. The observed limits are less stringent than the expected limits because the data lie above the expected background in the three-lepton $e\mu$ OSSF search regions with $M_T > 160$ GeV and $75 < M_{ll} < 105$ GeV (see Fig. 5; Table 1).

9.2.2 Limits on chargino–neutralino production in the $WH + E_T^{\text{miss}}$ final state

To evaluate upper limits for the process of Fig. 2 (center), we combine the results of the single-lepton, SS dilepton, and multilepton searches described in Sect. 7. Figure 16 (bottom) displays the observed limits for the combination of these analyses. The multilepton search provides the best sensitivity at low $m_{\tilde{\chi}}$, while the single-lepton search dominates at high $m_{\tilde{\chi}}$. The same-sign dilepton search contributes to the combination at low $m_{\tilde{\chi}}$. In Appendix C the observed and expected results for the $WH + E_T^{\text{miss}}$ final state are presented as a function of $m_{\tilde{\chi}}$, for a fixed mass $m_{\tilde{\chi}_1} = 1$ GeV, for each of the three search regions and their combination.

9.3 Limits on a Z-boson enriched GMSB model

We also consider a gauge-mediated symmetry breaking (GMSB) Z-boson enriched higgsino model which predicts an enhanced branching fraction to the $ZZ + E_T^{\text{miss}}$ final state. The LSP in this model is an almost massless gravitino ($\tilde{G}$), the next-to-lightest SUSY particle is a higgsino $\tilde{\chi}_1^0$, and the...
The results are presented in Fig. 17. Fig. 17 Interpretation of the results of the Z + dijet search, the three- and four-lepton searches, and their combination, in the GMSB scenario discussed in the text. The observed and expected 95% CL upper limits on the cross section are indicated as a function of the higgsino mass parameter $\mu$, and are compared to the theoretical cross section.

The $\chi^+_1$ and $\chi^0_2$ particles are nearly mass degenerate with the $\chi^0_1$. We set the gaugino mass parameters to $M_1 = M_2 = 1$ TeV and the ratio of Higgs bosons vacuum expectation values to $\tan\beta = 2$. The results are presented as a function of the higgsino mass parameter $\mu$, where $m_{\chi^0_1} \approx m_{\chi^0_2} \approx m_{\tilde{\chi}^0_1} \approx \mu$. To within typical mass differences of a few GeV. The branching fraction to the $Z\tilde{\chi}^0_1 \tilde{\chi}^0_1$ final state varies from 100% at $\mu = 130$ GeV to 85% at $\mu = 420$ GeV. We use the results of the three-lepton (Sect. 3), four-lepton (Sect. 4), and $WZ/ZZ + E_T^{miss}$ (Sect. 6) searches to constrain the GMSB scenario. The results are presented in Fig. 17.

9.4 Limits on chargino and slepton pair production

Figure 18 shows limits on the chargino and slepton pair-production cross section times branching fraction for the processes of Fig. 3. The limits for chargino pair production are determined using both the opposite- and same-flavor dilepton search regions discussed in Sect. 8, while the limits for slepton pair production are set using only the same-flavor dilepton search region. The production cross sections for left-handed sleptons are larger than those for right-handed sleptons, enhancing the sensitivity.

Fig. 18 Interpretation of the results of the opposite-sign non-resonant dilepton search, in the models with (top) chargino pair production ($\tilde{\chi}^+_1 \tilde{\chi}^-_1$), (center) left-handed slepton pair production ($\tilde{\ell}_L \tilde{\ell}_L$), and (bottom) right-handed slepton pair production ($\tilde{\ell}_R \tilde{\ell}_R$). The shading indicates the 95% CL upper limits on the cross section times branching fraction, and the contours the excluded regions assuming the NLO+NLL signal cross sections.

10 Summary

This paper presents searches for the direct electroweak pair production of supersymmetric charginos, neutralinos, and sleptons in a wide variety of signatures with leptons, and W, Z, and Higgs bosons. Results are based on a sample of proton-proton collision data collected at center-of-mass energy $\sqrt{s} = 8$ TeV with the CMS detector in 2012, corresponding to an integrated luminosity of 19.5 fb$^{-1}$.
The direct electroweak production of SUSY particles may result in several different signal topologies with one or more leptons and missing transverse energy ($E_T^{\text{miss}}$). The relative sensitivity of each signature depends on unknown parameters, including the SUSY particle masses. This situation, along with the relatively small cross sections typical of electroweak SUSY production, motivates a strategy based on multiple dedicated search regions that target each possible signal topology. In each of these search regions, the data are found to be in agreement with the standard model background expectations. No significant evidence for a signal-like excess is observed.

The results are interpreted in the context of models dominated by direct electroweak SUSY production. Several of the interpretation results are summarized in Fig. 19. We consider models with a wino-like chargino and neutralino pair with degenerate mass $m_{\tilde{\chi}}$, and a bino-like lightest SUSY particle with mass $m_{1\text{SP}}$. We also consider the presence of light sleptons, either produced in the decays of charginos or neutralinos, or produced directly in pairs. The limits on the signal production cross sections are most stringent in the region of parameter space with large $\Delta M \equiv m_{\tilde{\chi}} - m_{1\text{SP}}$ (or, for direct slepton production, $\Delta M \equiv m_{\tilde{\chi}} - m_{1\text{SP}}$), and less stringent in the region of small $\Delta M$, where the final-state objects are less energetic.

The electroweak SUSY process with the largest cross section is chargino–neutralino pair production. The resulting signal topologies depend on the properties of the sleptons. Models with light sleptons enhance the branching fraction to final states with three leptons. Depending on the left/right mixing and flavor of these sleptons, our results probe charginos and neutralinos with masses up to 320, 620, and 720 GeV, for the $\tau$-dominated, $\tau$-enriched, and flavor-democratic scenarios, respectively. In such models, searches in the same-sign dilepton final state enhance the sensitivity in the experimentally challenging region with small $\Delta M$.

Models without light sleptons lead to $WZ + E_T^{\text{miss}}$ or $WH + E_T^{\text{miss}}$ signatures, with model-dependent branching fractions. To probe the $WZ + E_T^{\text{miss}}$ signature, searches in the three-lepton and Z boson plus jets (with leptonic Z decay) final states are performed. To probe the $WH + E_T^{\text{miss}}$ signature, searches are performed in the single-lepton final state with $H \rightarrow b\bar{b}$, in the same-sign dilepton final state with $H \rightarrow W(\ell\nu)W(\ell\nu)$, where $j$ denotes a jet, and in final states with three or more leptons with $H \rightarrow W^+W^-, ZZ$, or $\tau^+\tau^-$. If the $WZ + E_T^{\text{miss}}$ ($WH + E_T^{\text{miss}}$) branching fraction is assumed to be 100%, our results probe charginos and neutralinos with masses up to 270 GeV (200 GeV). The $WZ + E_T^{\text{miss}}$ search is particularly important in the region with small $\Delta M$, where we probe charginos and neutralinos with masses up to 200 GeV. We also consider a specific model based on gauge-mediated SUSY breaking that predicts an enhancement in the $ZZ + E_T^{\text{miss}}$ production rate. Our results probe higgsinos with masses up to 330 GeV in this scenario.

Following chargino–neutralino pair production, the electroweak SUSY process with the largest cross section is chargino pair production, which leads to a final state consisting of an opposite-sign lepton pair and $E_T^{\text{miss}}$. Our results probe chargino masses up to 540 GeV in a scenario with light sleptons. The direct pair production of sleptons leads to a similar signature, with a lower cross section. For left-handed (right-handed) sleptons, our results probe sleptons with masses up to 260 (180) GeV.
Acknowledgments We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: the Austrian Federal Ministry of Science, Research and Economy and the Austrian Science Fund; the Belgian Fonds de la Recherche Scientifique, and Fonds voor Wetenschappelijk Onderzoek; the Brazilian Funding Agencies (CNPq, CAPES, FAPERJ, and FAPESP); the Bulgarian Ministry of Education and Science; CERN; the Chinese Academy of Sciences, Ministry of Science and Technology, and National Natural Science Foundation of China; the Colombian Funding Agency (COLCIENCIAS); the Croatian Ministry of Science, Education and Sport, and the Croatian Science Foundation; the Research Promotion Foundation, Cyprus; the Ministry of Education and Research, Estonian Research Council via IUT23-4 and IUT23-6 and European Regional Development Fund, Estonia; the Academy of Finland, Finnish Ministry of Education and Culture, and Helsinki Institute of Physics; the Institut National de Physique Nucléaire et de Physique des Particules/CNRS, and Commissariat à l’Énergie Atomique et aux Énergies Alternatives/CEA, France; the Bundesministerium für Bildung und Forschung, Deutsche Forschungsgemeinschaft, and Helmholtz-Gemeinschaft Deutscher Forschungszentren, Germany; the General Secretariat for Research and Technology, Greece; the National Scientific Research Foundation, and National Innovation Office, Hungary; the Department of Atomic Energy and the Department of Science and Technology, India; the Institute for Studies in Theoretical Physics and Mathematics, Iran; the Science Foundation, Ireland; the Istituto Nazionale di Fisica Nucleare, Italy; the Korean Ministry of Education, Science and Technology and the World Class University program of NRF, Republic of Korea; the Lithuanian Academy of Sciences; the Ministry of Education, and University of Malaya (Malaysia); the Mexican Funding Agencies (CINVESTAV, CONACYT, SEP, and UASLP-FAI); the Ministry of Business, Innovation and Employment, New Zealand; the Pakistan Atomic Energy Commission; the Ministry of Science and Higher Education and the National Science Centre, Poland; the Fundação para a Ciência e a Tecnologia, Portugal; JINR, Dubna; the Ministry of Education and Science of the Russian Federation, the Federal Agency of Atomic Energy of the Russian Federation, Russian Academy of Sciences, and the Russian Foundation for Basic Research; the Ministry of Education, Science and Technological Development of Serbia; the Secretaría de Estado de Investigación, Desarrollo e Innovación y Programa Consolider-Ingenio 2010, Spain; the Swiss Funding Agencies (ETH Board, ETH Zurich, PSI, SNF, UniZH, Canton Zurich, and SER); the Ministry of Science and Technology, Taiwan; the Thailand Center of Excellence in Physics, the Institute for the Promotion of Teaching Science and Technology of Thailand, Special Task Force for Activating Research and the National Science and Technology Development Agency of Thailand; the Scientific and Technical Research Council of Turkey, and Turkish Atomic Energy Authority; the National Academy of Sciences of Ukraine, and State Fund for Fundamental Researches, Ukraine; the Science and Technology Facilities Council, UK; the US Department of Energy, and the US National Science Foundation. Appendix A: Additional plots for the three-lepton and four-lepton searches

This appendix presents additional results from the three-lepton and four-lepton searches. The distributions of $M_T$ versus $M_{\ell\ell}$ for three-lepton events are presented in Figs. 20, 21, 22, 23, 24 and 25. The corresponding numerical results are presented in Tables 11, 12 and 13. The distribution of $E_T^{\text{miss}}$ versus $M_{\ell\ell}$ for four-lepton events is presented in Fig. 26.

![Distribution of $M_T$ versus $M_{\ell\ell}$ for three-lepton events](image_url)
Fig. 21 The $E^\text{miss}_T$ distributions for three-lepton $ee\mu$ and $e\mu\mu$ events without an OSSF pair. The SM expectations are also shown. The $E^\text{miss}_T$ distributions for an example signal scenario is overlaid. The first (second) number in parentheses indicates the value of $m_{\tilde{\chi}}$ ($m_{\tilde{\chi}^0_1}$).

Fig. 22 Distribution of $M_T$ versus $M_{\ell\ell}$ for three-lepton events with a same-sign $ee$, $e\mu$, or $\mu\mu$ pair and one $\tau_h$. $M_{\ell\ell}$ is calculated by combining opposite-sign leptons and choosing the pair closest to the corresponding dilepton mass determined from $Z \rightarrow \tau\tau$ simulation. $M_T$ is calculated using the remaining lepton.
Fig. 23 The $E_T^{\text{miss}}$ distributions for three-lepton events with a same-sign ee, e$\mu$, or $\mu\mu$ pair and one $\tau_h$. The SM expectations are also shown. The $E_T^{\text{miss}}$ distributions for an example signal scenario is overlaid. The first (second) number in parentheses indicates the value of $m_{\tilde{\chi}^0_1}$ ($m_{\tilde{\chi}^0_1}$).

Fig. 24 Distribution of $M_T$ versus $M_{\ell\ell}$ for three-lepton events with an opposite-sign e$\mu$ pair and one $\tau_h$. $M_{\ell\ell}$ is calculated by combining opposite-sign leptons and choosing the pair closest to the corresponding dilepton mass determined from $Z \rightarrow \tau\tau$ simulation. $M_T$ is calculated using the remaining lepton.
Fig. 25 The $E_{\text{T}}^{\text{miss}}$ distributions for three-lepton events with an opposite-sign $e\mu$ pair and one $\tau_h$. The SM expectations are also shown. The $E_{\text{T}}^{\text{miss}}$ distributions for an example signal scenario is overlaid. The first (second) number in parentheses indicates the value of $m_{\tilde{\chi}}$ ($m_{\tilde{\tau}^0}$).

Table 11  Observed yields and SM expectations for three-lepton $e\mu e\mu$ and $e\mu\tau$ events without an OSSF pair. The uncertainties include both the statistical and systematic components.

Fig. 26 \(E_T^{\text{miss}}\) versus \(M_\ell\ell\) for four-lepton events with an on-Z OSSF pair and no \(\tau_h\). The legend indicates the flavor breakdown of events. For events with two OSSF pairs, we choose the pair with mass closest to the \(Z\) boson mass.
Appendix B: Additional results for the multilepton analysis

In this appendix, we present similar results as those presented in Table 7 for the multilepton analysis of Sect. 7.3 but for different values of $m_{\tilde{\chi}}$ (Tables 14, 15, 16, 17).

### Table 14
Multilepton results for the $m_{\tilde{\chi}} = 150$ GeV, $m_{\tilde{\chi}^0} = 1$ GeV scenario. See Table 7 for details.

| $N_{\tau_h}$ | OSSF pair | $E_T^{\text{miss}}$ (GeV) | Data | Total SM | Signal |

Appendix C: One-dimensional exclusion plots in the WH + $E_T^{\text{miss}}$ final state

In Fig. 27, the cross section upper limits for the WH + $E_T^{\text{miss}}$ signal model are presented as a function of $m_{\tilde{T}}$, for a fixed mass $m_{\tilde{T}^0} = 1$ GeV, both individually from the three search regions and their combination.

![Graphs showing cross section upper limits and expected limits with theoretical uncertainty](image)

**Fig. 27** The interpretations of the results from (upper left) the single-lepton search, (upper right) the same-sign dilepton search, (lower left) the multilepton search, and (lower right) the combination of the three searches. The black curves show the expected (dashed) and observed (solid) limits on the $\tilde{T}_1^1$ $\tilde{T}_2^0$ cross section times $B(\tilde{T}_1^1 \tilde{T}_2^0 \rightarrow \text{WH} + E_T^{\text{miss}})$.

The green band shows the one-standard-deviation variation of the expected limit due to experimental uncertainties. The solid blue curve shows the theoretical prediction for the cross section, with the dashed blue bands indicating the uncertainty of the cross section calculation.

† Deceased
1: Also at Vienna University of Technology, Vienna, Austria
2: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
3: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
4: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia
5: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
6: Also at Universidade Estadual de Campinas, Campinas, Brazil
7: Also at California Institute of Technology, Pasadena, USA
8: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
9: Also at Joint Institute for Nuclear Research, Dubna, Russia
10: Also at Suez University, Suez, Egypt
11: Also at Cairo University, Cairo, Egypt
12: Also at Fayoum University, El-Fayoum, Egypt
13: Also at British University in Egypt, Cairo, Egypt
14: Now at Ain Shams University, Cairo, Egypt
15: Also at Université de Haute Alsace, Mulhouse, France
16: Also at Brandenburg University of Technology, Cottbus, Germany
17: Also at The University of Kansas, Lawrence, USA
18: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
19: Also at Eötvös Loránd University, Budapest, Hungary
20: Also at University of Debrecen, Debrecen, Hungary
21: Now at King Abdulaziz University, Jeddah, Saudi Arabia
22: Also at University of Visva-Bharati, Santiniketan, India
23: Also at University of Ruhuna, Matara, Sri Lanka
24: Also at Isfahan University of Technology, Isfahan, Iran
25: Also at Sharif University of Technology, Tehran, Iran
26: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
27: Also at Laboratori Nazionali di Legnaro dell’INFN, Legnaro, Italy
28: Also at Università degli Studi di Siena, Siena, Italy
29: Also at Centre National de la Recherche Scientifique (CNRS)-IN2P3, Paris, France
30: Also at Purdue University, West Lafayette, USA
31: Also at Universidad Michoacana de San Nicolas de Hidalgo, Morelia, Mexico
32: Also at Institute for Nuclear Research, Moscow, Russia
33: Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan
34: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
35: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
36: Also at Facoltà Ingegneria, Università di Roma, Rome, Italy
37: Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy
38: Also at University of Athens, Athens, Greece
39: Also at Paul Scherrer Institut, Villigen, Switzerland
40: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
41: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
42: Also at Gaziosmanpasa University, Tokat, Turkey
43: Also at Adiyaman University, Adiyaman, Turkey
44: Also at Cag University, Mersin, Turkey
45: Also at Mersin University, Mersin, Turkey
46: Also at Izmir Institute of Technology, Izmir, Turkey
47: Also at Ozyegin University, Istanbul, Turkey
48: Also at Kafkas University, Kars, Turkey
49: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
50: Also at Rutherford Appleton Laboratory, Didcot, UK
51: Also at School of Physics and Astronomy, University of Southampton, Southampton, UK
52: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
53: Also at Argonne National Laboratory, Argonne, USA
54: Also at Erzincan University, Erzincan, Turkey
55: Also at Yildiz Technical University, Istanbul, Turkey
56: Also at Texas A&M University at Qatar, Doha, Qatar
57: Also at Kyungpook National University, Daegu, Korea
