Abstract

The cyanobacterial circadian clock oscillator is composed of three clock proteins—KaiA, KaiB, and KaiC, and interactions among the three Kai proteins generate clock oscillation in vitro. However, the regulation of these interactions remains to be solved. Here, we demonstrated that ATP regulates formation of the KaiB-KaiC complex. In the absence of ATP, KaiC was monomeric (KaiC<sub>1 mer</sub>) and formed a complex with KaiB. The addition of ATP plus Mg<sup>2+</sup> (Mg-ATP), but not that of ATP only, to the KaiB-KaiC<sub>1 mer</sub> complex induced the hexamerization of KaiC and the concomitant release of KaiB from the KaiB-KaiC<sub>1 mer</sub> complex, indicating that Mg-ATP and KaiB compete each other for KaiC. In the presence of ATP and Mg<sup>2+</sup> (Mg-ATP), KaiC became a homohexameric ATPase (KaiC<sub>6 mer</sub>) with bound Mg-ATP and formed a complex with KaiB, but KaiC hexamerized by unhydrolyzable substrates such as ATP and Mg-ATP analogs, did not. A KaiC N-terminal domain protein, but not its C-terminal one, formed a complex with KaiB, indicating that KaiC associates with KaiB via its N-terminal domain. A mutant KaiC<sub>6 mer</sub> lacking N-terminal ATPase activity did not form a complex with KaiB whereas a mutant lacking C-terminal ATPase activity did. Thus, the N-terminal domain of KaiC is responsible for formation of the KaiB-KaiC complex, and the hydrolysis of the ATP bound to N-terminal ATPase motifs on KaiC<sub>6 mer</sub> is required for formation of the KaiB-KaiC<sub>6 mer</sub> complex. KaiC<sub>6 mer</sub> that had been hexamerized with ADP plus aluminum fluoride, which are considered to mimic ADP-Pi state, formed a complex with KaiB, suggesting that KaiB is able to associate with KaiC<sub>6 mer</sub> with bound ADP-Pi.

Introduction

Circadian rhythms—oscillations that regulate metabolic and behavioral activity in approximately 24-h periods—are observed in almost all organisms from prokaryotes to eukaryotes. Cyanobacteria are the simplest organisms to exhibit circadian rhythms [1]. The gene cluster kaiABC that is essential for the generation of circadian rhythms has been cloned and analyzed in the cyanobacterium Synechococcus sp. strain PCC 7942 (hereafter Synechococcus) [2]. The cyanobacterial clock oscillator is composed of only three clock proteins, KaiA, KaiB, and KaiC. Circadian oscillations are generated at the phosphorylation level [3] and ATPase activity [4] of KaiC and the formation of complexes between the proteins [5,6]. KaiC is a homohexameric ATP-binding protein with autokinase activity [7-9], very weak temperature-independent (temperature-compensated) ATPase activity [4,10], and autophosphatase activity [11,12]. The KaiC subunit has a duplicated structure composed of N-terminal and C-terminal domains, and each has a series of ATPase motifs (a Walker’s motif A, a Walker’s motif B, and a catalytic glutamate (CatE; We named the N-terminal CatE and C-terminal CatE as CatE1 and CatE2, respectively.)) (Figure 1A) [2,13]. KaiC has two phosphorylation sites, Ser431 and Thr432, in its C-terminal domain (Figure 1A). A mutant KaiC with aspartate substitutions at the two phosphorylation sites, KaiC<sub>S431D&hellip;</sub> (KaiC<sub>DD</sub>), is considered to mimic the fully phosphorylated state of KaiC [14], and a mutant KaiC with alanine substitutions at the two phosphorylation sites, KaiC<sub>S431A&hellip;</sub> (KaiC<sub>AA</sub>), is considered to mimic fully unphosphorylated state of KaiC [15]. KaiC<sub>DD</sub> showed higher affinity with KaiB than KaiC<sub>AA</sub> [5,15-18]. KaiA is a homodimeric protein [9,19,20] that enhances the
phosphorylation level [9,21,22] and ATPase activity [4,10] of KaiC. KaiB is a homotetrameric protein [23-25], and it has a positively charged cleft flanked by two negatively charged ridges [24]. KaiB suppresses the autokinase activity [22,26] and ATPase activity [4] of KaiC. KaiC associates with KaiA [8,9] and KaiB [25,27], and KaiB also associates directly with KaiA [16,28,29]. These interactions are essential for the generation of clock oscillation. On interaction with hexameric KaiC (KaiC\textsubscript{6mer}), tetrameric KaiB (KaiB\textsubscript{4mer}) likely dissociates into two dimeric KaiB (KaiB\textsubscript{2mer}) and forms a complex comprising one molecule of KaiC\textsubscript{6mer} and two of KaiB\textsubscript{2mer} [17]. Previously, we have shown that KaiB\textsubscript{1-94}-KaiC\textsubscript{DD}\textsubscript{6mer} complex (350 ± 20 kDa) consists of two molecules of KaiB\textsubscript{1-94} (dimeric) and one molecule of KaiC\textsubscript{DD}\textsubscript{6mer} and also have shown data suggesting that KaiB\textsubscript{1-94},KaiC\textsubscript{DD}\textsubscript{6mer} complex (366 ± 20 kDa) consists of two molecules of dimerized KaiB\textsubscript{1-94} (KaiB\textsubscript{2mer}) and one molecule of KaiC\textsubscript{DD}\textsubscript{6mer} [17]. The histidine kinase SasA, which is the first component of the main output pathway that transduces clock oscillation to genome-wide transcription cycles [30], competes with KaiB to form a complex with KaiC [17], and SasA and KaiC associate through their N-terminal domains [14]. How the KaiB-KaiC interaction is regulated, however, remains unknown.

Here, we investigated the interaction of KaiC with KaiB \textit{in vitro} and found that KaiC associates with KaiB via its N-terminal domain and that ATP regulates the KaiB-KaiC interaction. We propose a model for ATP regulation of KaiB-KaiC interaction.

\textbf{Materials and Methods}

\textbf{Preparation of Kai protein}

We produced recombinant Kai proteins derived from the thermophilic cyanobacterium \textit{Thermocyclus elongatus} BP-1 using \textit{Escherichia coli} as a host, as described previously, with modifications [13]. The plasmids expressing KaiA whose subunit consists of 283 amino acid residues, wild-type KaiB (KaiB\textsubscript{WT}; pTeka\textit{B}B\textsubscript{WT}), whose subunit consists of 108 amino acid residues, a mutant KaiB with a C-terminal deletion of residues 95 to 108 (KaiB\textsubscript{1-94}; pTeka\textit{B}B\textsubscript{1-94}), wild-type KaiC (KaiC\textsubscript{WT}; pTeka\textit{C}C\textsubscript{WT}), whose subunit consists of 516 amino acid residues, and mutant KaiCs—a mutant KaiC with aspartate substitutions at the two phosphorylation sites that is considered to mimic the fully phosphorylated state of KaiC, KaiC\textsubscript{1-94}D\textsubscript{1,2} (KaiC\textsubscript{DD}), a mutant KaiC with asparagine substitutions at the two phosphorylation sites that is considered to mimic fully unphosphorylated state of KaiC, KaiC\textsubscript{1-94}N\textsubscript{1,2} (KaiC\textsubscript{NN}), a mutant KaiC with glutamine substitutions at the two deduced catalytic glutamate residues of the C-terminal ATPase motifs that lacks the C-terminal ATPase activity of KaiC, \textit{KaiC\textsubscript{CDE}\textsubscript{3,4}−} (pTeka\textit{C}C\textsubscript{CDE}), \textit{KaiC\textsubscript{CDE}\textsubscript{2,3,4}−} (pTeka\textit{C}C\textsubscript{CDE}), an N-terminal domain mutant protein of residues 1 to 268 (Kai\textsubscript{NC}; pTeka\textit{C}C\textsubscript{NC}), and a C-terminal domain mutant protein of residues 269 to 518 with a mutation at asparagine substitutions at the two KaiC phosphorylation sites (KaiC\textsubscript{CDD}; pTeka\textit{C}C\textsubscript{CDD})—have been described previously [8,28]. We constructed plasmids for the production of KaiC\textsubscript{DD}\textsubscript{E} (pTeka\textit{C}C\textsubscript{DD}E), which is deficient in the N-terminal ATP binding site (N-terminal ATPase motifs) and carries aspartate substitutions at the two phosphorylation sites on the C-terminal domain (DD mutation), and \textit{KaiC\textsubscript{CDE}\textsubscript{1,2}−} (pTeka\textit{C}C\textsubscript{CDE}), which is deficient in the N-terminal ATPase and carries the DD mutation, by replacing a 1.25-kb BamHI-EcoRI fragment carrying the 3′-region of each kaiC gene in pTeka\textit{C}C\textit{P}HH and pTeka\textit{C}C\textsubscript{DE}, respectively, with that of KaiC\textsubscript{DD}. We constructed a plasmid for KaiC\textsubscript{DD}\textsubscript{E} (pTeka\textit{C}C\textsubscript{DD}E), which is deficient in the N-terminal ATP binding site and carries the DD mutation as described previously [13]. We purified KaiA, KaiB, and KaiC as described previously [28] and stored them at -85 °C until used. KaiA is a dimer [9,19,20], KaiB\textsubscript{WT} tetramer [23-25], and KaiC\textsubscript{1-94} dimer [17]. Thus unless otherwise stated, we expressed the concentrations of KaiA, KaiB\textsubscript{WT}, KaiB\textsubscript{1-94}, KaiC\textsubscript{DD}, and KaiC\textsubscript{DD} as those of a dimer, tetramer, dimer, monomer, and hexamer, respectively.

\textbf{Preparation of KaiC\textsubscript{DD}mer}

To allow the hexamerization of KaiC, we incubated KaiC\textsubscript{DD}mer with 1 mM ATP or 1 mM ATP analogs, 5'-adenylylimidodiphosphate (AMPNNP) and adenosine 5'-O-(3-thio) triphosphate (APYPS), in the presence of 5 mM MgCl\textsubscript{2} in 20 mM Tris-HCl buffer (pH 7.5) containing 150 mM NaCl at 20 °C for 20 min. We then subjected the reaction mixtures to gel filtration chromatography on a Superdex 200/HR 10/30 column (GE Healthcare) equilibrated with 20 mM HEPES-NaOH buffer (pH 7.5) containing 150 mM NaCl (reaction buffer), 0.1 mM ATP (or ATP analogs) and 5 mM MgCl\textsubscript{2} at 4 °C, and we collected fractions containing KaiC\textsubscript{DD}mer. We similarly prepared KaiC\textsubscript{DD}mer in the absence of MgCl\textsubscript{2}. Unless otherwise stated, KaiC\textsubscript{DD}mer means KaiC hexamerized with 1 mM ATP plus 5 mM MgCl\textsubscript{2} (Mg-ATP). The phosphorylation level of the KaiC\textsubscript{DD}mer preparations used here was about 30 %.

\textbf{Assay for the complex formation of monomeric KaiC (KaiC\textsubscript{DD}mer) with KaiBs by native polyacrylamide gel electrophoresis (native PAGE)}

We incubated reaction mixtures containing 15 μM KaiB\textsubscript{1-94} or 7.5 μM KaiB\textsubscript{WT} and 5 μM KaiC\textsubscript{DD} or 2.5 μM KaiC\textsubscript{DD}mer at 4 °C in reaction buffer and subjected 20-μl aliquots to native PAGE (native-PAGE and 2-dimensional sodium dodecyl sulfate (SDS)-PAGE). We incubated reaction mixtures containing 10 μM KaiB\textsubscript{1-94} and 6 μM KaiC\textsubscript{DD}mer at 4, 25, or 40 °C in reaction buffer and subjected aliquots to native PAGE. We confirmed the presence of KaiB\textsubscript{1-94} and KaiC in the complex bands by SDS-PAGE on 18 % gels, as described previously [8].

\textbf{Assay for formation of the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD}mer complex by native-PAGE and 2-dimensional sodium dodecyl sulfate (SDS)-PAGE}

We incubated reaction mixtures containing 10 μM KaiB\textsubscript{1-94} and 6 μM KaiC\textsubscript{DD}mer at 4, 25, or 40 °C in reaction buffer and subjected aliquots to native PAGE. We confirmed the presence of KaiB\textsubscript{1-94} and KaiC in the complex bands by SDS-PAGE followed by SDS-PAGE on 18 % gels, as described previously [8].
Figure 1. The sequence motifs of KaiC and KaiB-KaiC complex formation. A. A diagram of the sequence motifs of KaiC. B. Time courses of KaiB-KaiC<sub>DD</sub><sup>6mer</sup> complex formation. KaiB<sub>WT</sub> (1 μM) and KaiB<sub>1-94</sub> (2 μM) were separately incubated with 1 μM KaiC<sub>DD</sub> in reaction buffer containing Mg-ATP at 4 °C or 40 °C for the various periods indicated, and then aliquots of the reaction mixtures were subjected to native PAGE on 10 % gels. After staining the gels with CBB to visualize proteins, we estimated the amounts of KaiBs-KaiC<sub>DD</sub><sup>6mer</sup> complex by densitometry. We used the maximum value obtained at a time of 6 h as the maximum value. KaiBs added and temperature conditions: open circles, KaiB<sub>WT</sub> (40 °C); closed circles, KaiB<sub>1-94</sub> (40 °C); open squares, KaiB<sub>1-94</sub> (4 °C). C. A native PAGE gel of the reaction products of KaiC<sub>DD</sub><sup>1mer</sup> with KaiB<sub>1-94</sub>. Reaction mixtures containing 15 μM KaiB<sub>1-94</sub> and 5 μM KaiC<sub>DD</sub><sup>1mer</sup> in reaction buffer were incubated at 4 °C for 6 h and then subjected to native PAGE. Proteins were visualized by CBB staining of the gel. Because KaiB<sub>1-94</sub> has an isoelectric point of 9.7, it moved in the opposite direction and could not detect by native PAGE. D. A native PAGE gel of the reaction products of KaiC<sub>DD</sub><sup>1mer</sup> with KaiB<sub>WT</sub>. Reaction mixtures containing 7.5 μM KaiB<sub>WT</sub> and 5 μM KaiC<sub>DD</sub><sup>1mer</sup> in reaction buffer were incubated at 4 °C for 6 h and then subjected to native-PAGE. E. Time course of KaiB<sub>1-94</sub>-KaiC<sub>DD</sub><sup>1mer</sup> complex formation. Reaction mixtures containing 5 μM KaiB<sub>1-94</sub> and 5 μM KaiC<sub>DD</sub><sup>1mer</sup> in reaction buffer were incubated at 4 °C for the periods indicated and then subjected to native PAGE. We used the value obtained at a time of 9 h as the maximum value. A typical experimental data is shown. F. KaiB<sub>1-94</sub> concentration-dependence of the KaiB<sub>1-94</sub>-KaiC<sub>DD</sub><sup>1mer</sup> complex formation. Reaction mixtures containing 1 μM KaiC<sub>DD</sub><sup>1mer</sup> and various amounts (0.5, 0.75, 1.0, 1.25, 1.5, 2.0, 2.5, 3.0, and 4.0 μM) of KaiB<sub>1-94</sub> in reaction buffer were incubated at 4 °C for 6 h and then subjected to native PAGE. We used the value obtained at a KaiB<sub>1-94</sub> concentration of 4 μM as the maximum value. A typical experimental data is shown.

Assay for formation of the KaiB<sub>1-94</sub>-KaiC<sub>1mer</sub> complex and KaiB<sub>1-94</sub>-KaiC<sub>6mer</sub> complex by gel filtration chromatography

To assay for formation of the KaiB<sub>1-94</sub>-KaiC<sub>1mer</sub> complex and the KaiB<sub>1-94</sub>-KaiC<sub>6mer</sub> complex, we incubated reaction mixtures containing 36 μM KaiB<sub>1-94</sub> and 12 μM KaiC<sub>1mer</sub> in reaction buffer and those containing 7.5 μM KaiB<sub>1-94</sub> and 2.5 μM KaiC<sub>6mer</sub> (KaiC<sub>WT</sub> or mutant KaiCs) in the buffer with (for KaiC<sub>1mer</sub>) or without (for KaiC<sub>6mer</sub>) Mg-ATP at 4 °C for 6 h. We then analyzed the mixtures by gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer at 4 °C for 2 h to form KaiC<sub>6mer</sub> (ADP-AlF<sub>3</sub>) [31]. We then mixed the reaction mixtures with an equal volume of 0 or 60 μM KaiB<sub>1-94</sub> in the same buffer and incubated them further at 25 °C for 6 h. We subjected the reaction mixtures to gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer at 4 °C. We analyzed all peak fractions by SDS-PAGE on 18 % gels, and then stained the gels with CBB.

Assay for the time course of formation of the KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub>1mer complex

We incubated KaiC<sub>D0D</sub><sup>1mer</sup> (5 μM) with 5 μM KaiB<sub>1-94</sub> in reaction buffer at 4 °C for various periods and subjected aliquots of the reaction mixtures to native PAGE on 10 % gels, staining the gels with CBB as described above. We estimated the amount of KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub><sup>1mer</sup> complex from the intensity of the band by densitometry as described above.

KaiB<sub>1-94</sub>-concentration dependence of KaiB-KaiC<sub>1mer</sub> complex formation

We incubated 1 μM KaiC<sub>D0D</sub><sup>1mer</sup> with various amounts of KaiB<sub>1-94</sub> (0.5, 0.75, 1.0, 1.25, 1.5, 2.0, 2.5, 3.0, and 4.0 μM) in reaction buffer at 4 °C for 6 h. Other conditions were the same as described above.

Assay for Mg-ATP-induced dissociation of the KaiB<sub>1-94</sub>-KaiC<sub>1mer</sub> complex

We assayed the ATP-induced hexamerization of KaiC<sub>D0D</sub><sup>1mer</sup> in the KaiB<sub>1-94</sub>-KaiC<sub>1mer</sub> complex and the concomitant release of KaiB<sub>1-94</sub>. To obtain the KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub><sup>1mer</sup> complex, we incubated reaction mixtures containing 24 μM KaiB<sub>1-94</sub> and 24 μM KaiC<sub>D0D</sub><sup>1mer</sup> in reaction buffer at 4 °C for 16 h and then subjected the mixtures to gel filtration chromatography on a Superdex 75/HR 10/30 column (GE Healthcare) equilibrated with reaction buffer at 4 °C. We added 1 mM ATP with or without 5 mM MgCl<sub>2</sub> to the obtained KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub><sup>1mer</sup> complex and then incubated the reaction mixtures in reaction buffer at 4 °C for 6 h. Then, we subjected the reaction mixtures to gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer at 4 °C. We analyzed all peak fractions by SDS-PAGE on 18 % gels, and then stained the gels with CBB.

Preparation of KaiC<sub>6mer</sub> formed with ADP and aluminum fluoride (KaiC<sub>6mer</sub> (ADP-AlF<sub>3</sub>)) and assay for the KaiB<sub>1-94</sub>-KaiC<sub>6mer</sub> (ADP-AlF<sub>3</sub>) complex

We incubated KaiC<sub>6mer</sub> (20 μM) in reaction buffer containing 6 mM ADP, 30 mM MgCl<sub>2</sub>, 2.5 mM NaF, and 2.5 mM AlCl<sub>3</sub> at 25 °C for 2 h to form KaiC<sub>6mer</sub> (ADP-AlF<sub>3</sub>) [31]. We then mixed the reaction mixtures with an equal volume of 0 or 60 μM KaiB<sub>1-94</sub> in the same buffer and incubated them further at 25 °C for 6 h. We subjected the reaction mixtures to gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer at 4 °C. We analyzed all peak fractions by SDS-PAGE on 18 % gels, and then stained the gels with CBB.

Assay for the KaiA-enhanced autophosphorylation of KaiC<sub>6mer</sub>

We incubated reaction mixtures containing 0.5 μM KaiC<sub>6mer</sub>, 0.5 μM KaiA, and Mg-ATP in reaction buffer at 40 °C for various periods. We then subjected aliquots of the reaction mixtures to SDS-PAGE on 12.5 % gels (acrylamide: bisacrylamide = 144: 1), and stained the gels with CBB. We estimated the amount of the protein from the intensities of bands by densitometry as described above.

Assay for ATPase activity

We measured the ATPase activity of KaiC<sub>6mer</sub> using BIOMOL GREEN (Enzo Life Science International, Inc., Farmingdale, New York, USA) according to the supplier's instruction manual. We incubated KaiC<sub>6mer</sub> (1 μM) in reaction buffer containing Mg-ATP at 4 °C for 6 h, and then incubated 50-μl aliquots of the reaction mixtures with 50 μl BIOMOL GREEN at 25 °C for 20 min. We measured the absorbance of the samples at 620 nm (A<sub>620</sub>) using an ARVO X4 plate reader (PerkinElmer Inc., Waltham, MA, USA), calculated the amount of Pi released from ATP from triplicate experiments, and expressed the ATPase activity as mol Pi released per mol KaiC<sub>6mer</sub> per h at 4 °C. We showed the values after subtracting the buffer background (0.024 ± 0.03 ATP molecules/h).

Results

Association of KaiC<sub>1mer</sub> with KaiB<sub>1-94</sub>

At 40 °C, KaiB<sub>WT</sub> formed a complex with KaiC<sub>D0D</sub><sup>1mer</sup> (Figure 1B) but the complex formation took more than 9 h to reach a plateau (Figure 1B). KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub><sup>1mer</sup> complex formation, on the other hand, reached a plateau within 6 h with a time (τ<sub>1/2</sub>) of 1.2 h where the half maximal KaiB<sub>1-94</sub>-KaiC<sub>D0D</sub><sup>1mer</sup> complex formation occurred, and even at 4 °C showed no lag (Figure 1B).
1B). Thus, to analyze the formation of the KaiB-KaiC complex in detail, we used KaiB\textsubscript{1-94} and KaiC\textsubscript{1mer} at 4 °C.

First, we examined KaiC\textsubscript{1mer} complex formation with KaiB\textsubscript{1-94} and KaiB\textsubscript{WT}. When we incubated 5 μM KaiC\textsubscript{DD\textsubscript{1mer}} with 15 μM KaiB\textsubscript{1-94} or 7.5 μM KaiB\textsubscript{WT}, at 4 °C for 6 h, KaiC\textsubscript{DD\textsubscript{1mer}} formed a complex with KaiB\textsubscript{1-94} (Figure 1C and Table S1) as KaiC\textsubscript{6mer} (Figure 1B), whereas it showed only weak complex formation with KaiB\textsubscript{WT} (Figure 1D). The complex formation occurred without delay and reached a plateau at 6 h (Figure 1E). The time (t\textsubscript{1/2}) where the half maximal KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex formation occurred at 4 °C was about 2.5 h (Figure 1E). The concentration of KaiB\textsubscript{1-94} where the half maximal KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex formation occurred was about 0.7 μM (Figure 1F). This value falls within the concentration range at which clock oscillations occur in the in vitro KaiABC clock system [5].

KaiB-interacting domain of KaiC

The KaiC subunit is composed of an N-terminal domain (KaiC\textsubscript{N}) and a C-terminal domain (KaiC\textsubscript{C}) [32]. When we incubated 5 μM of KaiC\textsubscript{DD\textsubscript{1mer}} monomeric domain protein (KaiC\textsubscript{N\textsubscript{1mer}} or KaiC\textsubscript{C\textsubscript{DD\textsubscript{1mer}}}) with 30 μM KaiB\textsubscript{1-94} at 4 °C for 6 h, only KaiC\textsubscript{N\textsubscript{1mer}} formed a complex with KaiB\textsubscript{1-94} (Figures 2A and B, and Table S1). Even when the reaction mixtures were incubated at 25 °C, we did not detect any KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex (Figure 2B). Thus, the KaiB-interacting site of KaiC was located on the N-terminal domain of KaiC.

When we incubated 2.5 μM KaiC\textsubscript{N\textsubscript{1mer}} with 7.5 μM KaiB\textsubscript{1-94} in the presence of Mg-ATP, KaiC\textsubscript{N\textsubscript{1mer}} showed a weak association with KaiB\textsubscript{1-94} that was detected by gel filtration chromatography but not by Native PAGE (Figure 2C and Table S2). Unexpectedly, most KaiC\textsubscript{N\textsubscript{1mer}} became monomeric when it formed a complex with KaiB\textsubscript{1-94} (Figure 2C). KaiC\textsubscript{C\textsubscript{DD\textsubscript{1mer}}}, on the other hand, did not form a complex with KaiB\textsubscript{1-94} (Table S2). KaiC\textsubscript{1mer}, therefore, also associates with KaiB\textsubscript{1-94} via its N-terminal domain.

Mg-ATP-induced dissociation of the KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex

Addition of ATP as well as Mg-ATP was able to hexamerize KaiC\textsubscript{DD\textsubscript{1mer}} and KaiC\textsubscript{N\textsubscript{1mer}} (Figure 3A) as described previously [33]. When the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex was incubated in the presence of 1 mM ATP or 1 mM ATP plus 5 mM MgCl\textsubscript{2} (Mg-ATP) at 4 °C for 6 h, Mg-ATP, but not ATP, induced the hexamerization of KaiC\textsubscript{DD\textsubscript{1mer}} (Figure 3B) and the concomitant release of KaiB\textsubscript{1-94} (Figures 3B and 3C). We also detected a small amount of the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex (Figure 3C), which was likely formed from the KaiC\textsubscript{DD\textsubscript{1mer}} hexamerized by Mg-ATP, and the KaiB\textsubscript{1-94} released from the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex during incubation. These results suggest that Mg-ATP but not ATP reduced the affinity of KaiC\textsubscript{1mer} for KaiB\textsubscript{1-94} to dissociate the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex. When we examined the ATP- and Mg-ATP-induced oligomerization of KaiC\textsubscript{N} in the KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex, we obtained essentially the same results; Mg-ATP, to a much greater extent than ATP, induced oligomerization of KaiC\textsubscript{N} in the KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex (Figure 3B). These results suggest that Mg-ATP (and ATP) inhibited the association of KaiB\textsubscript{1-94} with the N-terminal domain of KaiC.

Effects of mutations in the ATPase motifs of KaiC on KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex formation

Both the N- and C-terminal domains of the KaiC subunit have a series of ATPase motifs (a Walker's motif A, a Walker's motif B, and a CatE [2]). When we examined the effects of mutations in those motifs on formation of KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complexes—using KaiCs with K53H and K294H mutations in Walker's motif A and CatE1 and CatE2 mutations in CatEs [32]—we found that all the mutants we examined (KaiC\textsubscript{K53H/DD\textsubscript{1mer}}, KaiC\textsubscript{CatE1/DD\textsubscript{1mer}} or KaiC\textsubscript{CatE2/DD\textsubscript{1mer}}) formed complexes with KaiB\textsubscript{1-94} (Figure 4A and Table S1). Thus, none of the mutations in the ATPase motifs affected formation of the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex that occurs in the absence of ATP.

When we examined KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex formation in the presence of Mg-ATP, both KaiC\textsubscript{K53H/DD\textsubscript{1mer}} and KaiC\textsubscript{CatE2/DD\textsubscript{1mer}}, which have a C-terminal ATPase motif mutation, as well as KaiC\textsubscript{DD\textsubscript{1mer}} control, formed complexes with KaiB\textsubscript{1-94} whereas KaiC\textsubscript{K53H/DD\textsubscript{1mer}} and KaiC\textsubscript{CatE1/DD\textsubscript{1mer}} did not (Figure 4B). Native PAGE followed by SDS-PAGE revealed that all the candidate complex bands examined contained both KaiB\textsubscript{1-94} and KaiC (a typical example is shown in Figure 4C). These results indicate that KaiC's N-terminal ATPase motifs were responsible for formation of the KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex that occurred in the presence of Mg-ATP. This observation is consistent with the finding described above that KaiC associates with KaiB\textsubscript{1-94} via its N-terminal domain (Figure 2) and that Mg-ATP (and ATP) inhibits the association (Table S2).

Effects of the ATP, Mg-ATP, Mg-AMPPNP, and Mg-ATP\textsubscript{S} used for the hexamerization of KaiC on KaiB\textsubscript{1-94}-KaiC\textsubscript{1mer} complex formation

The observations described above suggest that ATP hydrolysis followed by the release of ADP from the N-terminal ATPase motifs is required for KaiC\textsubscript{DD\textsubscript{1mer}} complex formation. We therefore examined whether the KaiC\textsubscript{DD\textsubscript{1mer}} hexamerized by unhydrolyzable substrate analogs of ATPases, ATP (KaiC\textsubscript{DD\textsubscript{1mer}} (ATP)), Mg-AMPPNP (KaiC\textsubscript{DD\textsubscript{1mer}} (Mg-AMPPNP)), and Mg-ATP\textsubscript{S} (KaiC\textsubscript{DD\textsubscript{1mer}} (Mg-ATP\textsubscript{S})) formed a complex with KaiB\textsubscript{1-94} and found that only KaiC\textsubscript{DD\textsubscript{1mer}} hexamerized with Mg-ATP (KaiC\textsubscript{DD\textsubscript{1mer}} (Mg-ATP)), which is a hydrolyzable substrate for ATPases, did (Figure 5A). These results support our hypothesis that hydrolysis of ATP in the N-terminal ATPase motifs is required for KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex formation because ATP and the unhydrolyzable substrates analogs examined inhibited KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex formation.

KaiC\textsubscript{1mer} (Mg-ADP-AlF\textsubscript{X}) forms a complex with KaiB\textsubscript{1-94}

Because ADP-AlF\textsubscript{X} mimics ADP-P\textsubscript{I}, we used gel filtration chromatography to determine whether Mg-ADP-AlF\textsubscript{X} hexamerizes KaiC\textsubscript{DD\textsubscript{1mer}} and confirmed that it did (Figure 5B). Next, we examined the possible complexes formed by KaiC\textsubscript{DD\textsubscript{1mer}} (Mg-ADP-AlF\textsubscript{X}) with KaiB\textsubscript{1-94}. KaiC\textsubscript{DD\textsubscript{1mer}} (Mg-ADP-AlF\textsubscript{X}) formed a complex with KaiB\textsubscript{1-94} (Figure 5B), but we also detected a KaiB\textsubscript{1-94}-KaiC\textsubscript{DD\textsubscript{1mer}} complex under conditions
Figure 2. Native PAGE gels, gel filtration chromatography elution profiles, and the immunoblots of the KaiB\textsubscript{1-94}-KaiC complexes. A, B. Native PAGE gels. Reaction mixtures containing 15 μM KaiB\textsubscript{1-94} and 5 μM KaiC\textsubscript{N\textsuperscript{1mer}} (A) or KaiC\textsubscript{C/DD\textsuperscript{1mer}} (B) were incubated at 4 °C for the periods indicated (hereafter, unless otherwise stated, 0 h shows data for samples taken at the onset of incubation) and subjected to native PAGE. Other conditions were the same as for Figure 1C legend. C. Gel filtration chromatography elution profiles and an immunoblot. Reaction mixtures containing 7.5 μM KaiB\textsubscript{1-94}, 2.5 μM KaiC\textsubscript{N\textsuperscript{6mer}}, and 1 mM ATP plus 5 mM MgCl\textsubscript{2} (Mg-ATP) were incubated at 4 °C for 6 h and then subjected to gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer containing 0.5 mM ATP and 5 mM MgCl\textsubscript{2} at 4 °C. We also separately analyzed KaiB\textsubscript{1-94} and KaiC\textsubscript{N\textsuperscript{6mer}} by gel filtration chromatography as controls. The peak fraction samples were subjected to SDS-PAGE, blotted to PVDF membranes, and reacted with an anti-KaiB antiserum. Other conditions were the same as for Figure 1C legend. Black solid line, KaiB\textsubscript{1-94} + KaiC\textsubscript{N\textsuperscript{6mer}}; gray solid line, KaiC\textsubscript{N\textsuperscript{6mer}}; black broken line, KaiB\textsubscript{1-94}.

doi: 10.1371/journal.pone.0080200.g004
wherein a substantial amount of KaiCDD1mer was not hexamerized (Figure 5B). This observation supports our above conclusion that ATP hydrolysis is required for formation of the KaiB1-94-KaiCDD6mer complex. Therefore, the conformation of

Figure 5. Effects of the ATP and ATP analogs used for the hexamerization of KaiC on formation of the KaiB1-94-KaiCDD6mer complex assayed by native PAGE and gel filtration chromatography. A. Native PAGE gels. Reaction mixtures were incubated at 4 °C for the periods indicated. Other conditions were the same as described for Figure 4B except that KaiCDD6mer (ATP), KaiCDD6mer (Mg-AMPPNP), and KaiCDD6mer (Mg-ATPγS) were used in the presence of 1 mM ATP, Mg-AMPPNP, and Mg-ATPγS, respectively. B. Gel filtration chromatography elution profiles of KaiCDD6mer (Mg-ADP-AlF₃) (dotted line) and a KaiB1-94-KaiCDD6mer (Mg-ADP-AlF₃) complex (solid line). KaiCDD1mer (20 μM) was incubated in reaction buffer containing 6 mM ADP, 30 mM MgCl₂, 2.5 mM NaF, and 2.5 mM AlCl₃ at 25 °C for 2 h, and the reaction mixtures were mixed with an equal volume of 0 or 60 μM KaiB1-94 in the same buffer and then further incubated at 25 °C for 6 h. The reaction mixtures were then subjected to gel filtration chromatography on a Superdex 200/HR 10/30 column equilibrated with reaction buffer at 4 °C. Other conditions were the same as described for Figure 2.

doi: 10.1371/journal.pone.0080200.g005
KaiC\textsubscript{DD}\textsuperscript{6mer} (Mg-ADP-P\textsubscript{i}) that allows complex formation with KaiB\textsubscript{1-94} may differ from that of KaiC\textsubscript{DD}\textsuperscript{6mer} (Mg-ATP) without ATP hydrolysis and that of KaiC\textsubscript{6mer} (ATP).

**Effects of KaiC phosphorylation-site mutations and autophosphorylation mutations on KaiB\textsubscript{1-94}-KaiC\textsubscript{6mer} complex formation**

We examined the effects of mutations in the two phosphorylation sites of KaiC on KaiB\textsubscript{1-94}-KaiC\textsubscript{6mer} complex formation. While KaiC\textsubscript{DD}\textsuperscript{6mer} (Figure 4D) and KaiC\textsubscript{DD}\textsuperscript{1mer} (Figure 5A) formed a complex with KaiB\textsubscript{1-94}, KaiC\textsubscript{DE} \textsuperscript{6mer} did not form such a complex (Figure 4D). These results are consistent with previous reports showing that phosphorylated KaiC (KaiC\textsubscript{DD} and KaiC\textsubscript{DE}, a mutant KaiC similar to KaiC\textsubscript{DD}) did not form complexes with KaiB\textsubscript{1-94} [5,16-18]. When KaiC\textsubscript{VT} \textsuperscript{6mer} was incubated with Mg-ATP in the presence of KaiA, it was highly phosphorylated (Figure 4E) [6,9,13,21,27,35]. The two upper bands correspond to the phosphorylated forms of KaiC whereas the lowest band corresponds to the unphosphorylated form of KaiC (Figure 4E) [3,13]. KaiC\textsubscript{AA}\textsuperscript{6mer}, KaiC\textsubscript{CUE}\textsuperscript{6mer}, and KaiC\textsubscript{2A}<\textsuperscript{6mer} did not show any phosphorylated bands even in the presence of KaiA (Figure 4E).

Next, we examined the effects of KaiC autophosphorylation mutations on KaiB\textsubscript{1-94}-KaiC\textsubscript{6mer} complex formation. In spite of lacking the autophosphorylation [13], both KaiC\textsubscript{20A}\textsuperscript{6mer} and KaiC\textsubscript{CUE}\textsuperscript{6mer} formed complexes with KaiB\textsubscript{1-94} (Figure 4D). Thus, phosphorylation of KaiC per se was not essential for KaiB\textsubscript{1-94}-KaiC\textsubscript{6mer} complex formation, although KaiC’s phosphorylation state might indirectly modulate complex formation.

**Effects of KaiC phosphorylation-site mutations on the N-terminal ATPase activity of KaiC**

To examine the effects of mutations in the two phosphorylation sites of KaiC on the N-terminal ATPase activity of KaiC, we compared the ATPase activities of KaiC\textsubscript{CUE}\textsubscript{3A}\textsuperscript{6mer}, KaiC\textsubscript{CUE}\textsubscript{2A}\textsuperscript{DD} \textsuperscript{6mer}, and KaiC\textsubscript{CUE}\textsuperscript{DE} \textsuperscript{6mer} because KaiC\textsubscript{CUE}\textsuperscript{2} lacks the C-terminal ATPase activity of KaiC [13]. The ATPase activities of KaiC\textsubscript{CUE}\textsubscript{DD} \textsuperscript{6mer} and KaiC\textsubscript{CUE}\textsubscript{DD} \textsuperscript{6mer} reflect the N-terminal ATPase activity while that of KaiC\textsubscript{DD} \textsuperscript{6mer} and KaiC\textsubscript{VT} \textsuperscript{6mer} reflect the total ATPase activity. The former activities were approximately half of the latter activities (Figure 6 and Table S4). These four KaiC\textsubscript{6mer} forms formed a complex with KaiB\textsubscript{1-94} (Tables S2 and S3). On the other hand, the ATPase activity of KaiC\textsubscript{AA}\textsuperscript{6mer}, which did not form a complex with KaiB\textsubscript{1-94} (Table S3), showed 6 times higher ATPase activity than KaiC\textsubscript{DD} \textsuperscript{6mer} and KaiC\textsubscript{VT} \textsuperscript{6mer} (Figure 6). In consistent with this, KaiC\textsubscript{AA} has been reported to show 2.5 times higher ATPase activity than KaiC\textsubscript{DD}, which is a mutant KaiC similar to KaiC\textsubscript{DD} [4]. The ATPase activity of KaiC\textsubscript{CUE}\textsubscript{3A}\textsuperscript{6mer}, which formed a complex with KaiB\textsubscript{1-94} that could only be detected by silver staining (Table S3), was more than 3 times as high as those of KaiC\textsubscript{CUE}\textsubscript{DD} \textsuperscript{6mer} and KaiC\textsubscript{CUE}\textsubscript{DE} \textsuperscript{6mer}. The ATPase activities of KaiC\textsubscript{CUE}\textsubscript{3A}\textsuperscript{6mer}, KaiC\textsubscript{CUE}\textsubscript{2A}\textsuperscript{DD} \textsuperscript{6mer}, and KaiC\textsubscript{CUE}\textsubscript{DE} \textsuperscript{6mer} all reflect the N-terminal ATPase activity of KaiC. Thus, although the N-terminal ATPase activity of KaiC is probably required for KaiC\textsubscript{6mer} to form a complex with KaiB\textsubscript{1-94}, its excessively high activity (KaiC\textsubscript{AA}\textsuperscript{6mer} and KaiC\textsubscript{CUE}\textsubscript{3A}\textsuperscript{6mer}) may inhibit complex formation. The ATPase activity of KaiC\textsubscript{CUE}\textsubscript{1DD} \textsuperscript{6mer} reflecting the C-terminal ATPase activity of KaiC was almost the same as that of KaiC\textsubscript{DD} \textsuperscript{6mer} and approximately half of that of KaiC\textsubscript{DD} \textsuperscript{6mer} (Figure 6 and Table S4), as described previously [10].

**Discussion**

Since KaiC\textsubscript{6mer} formed a complex with KaiB\textsubscript{1-94} (Figure 1C), the KaiC subunit per se is able to form a complex with KaiB. Recently, NMR analysis revealed that KaiC\textsubscript{6mer} forms a complex with KaiB via its N-terminal domain [29], and here KaiC (KaiC\textsubscript{6mer} as well as KaiC\textsubscript{1mer}) formed a complex with KaiB\textsubscript{1-94} via its N-terminal domain (Figure 2). ATP, Mg-ATP, Mg-AMPPNP, and Mg-ATP\textsubscript{S} hexamerize KaiC, probably by binding subunits [13,32,36,37]. KaiC\textsubscript{6mer} (ATP), KaiC\textsubscript{6mer} (Mg-AMPPNP), and KaiC\textsubscript{6mer} (Mg-ATP\textsubscript{S}) did not form a complex with KaiB\textsubscript{1-94} (Figure 5A). This indicates that when KaiC-bound ATP (or ATP analogs) is unhydrolyzable, KaiC does not form a complex with KaiB. KaiC\textsubscript{DD} \textsuperscript{6mer} (Mg-ADP-\textsubscript{AlF\textsubscript{3}}), which mimics the Mg-ADP-Pi state of KaiC\textsubscript{6mer}, formed a complex with KaiB\textsubscript{1-94} (Figure 5B). It is likely, therefore, that ATP regulates KaiB-KaiC\textsubscript{6mer} complex formation by hindering complex formation by KaiC\textsubscript{6mer}-bound ATP, and its hydrolysis is required for complex formation.

That mutations in the N-terminal but not its C-terminal ATPase motifs affected the complex formation of KaiC\textsubscript{6mer} (Mg-ATP) with KaiB\textsubscript{1-94} (Figure 4B) indicates that ATP hydrolysis by the N-terminal KaiC’s ATPase motifs is responsible for KaiB-KaiC\textsubscript{6mer} complex formation. These results are consistent with a recent report [38]. Because the KaiC\textsubscript{AA}\textsuperscript{6mer},KaiB\textsubscript{1-94} complex rapidly dissociated into a KaiB\textsubscript{1-94},KaiC\textsubscript{6mer} complex (Figure 2C), the partial dissociation (or relaxation) of the N-terminal domains of KaiC\textsubscript{6mer} probably occurred on the interaction of KaiC\textsubscript{6mer} with KaiB. This partial dissociation of the KaiC\textsubscript{6mer} N-terminal domains is likely required for formation of KaiB-KaiC\textsubscript{6mer} complex via KaiC\textsubscript{6mer}’s N-terminal domain. The relaxation of the KaiC\textsubscript{6mer} N-terminal domains on interaction of KaiB has been revealed recently by NMR analysis [29].

The KaiB molecule, which is a homotetramer organized as a dimer of dimers (KaiB\textsuperscript{6mer}) [24], probably dissociates into two dimers (KaiB\textsuperscript{3mer}) on interaction with KaiC\textsubscript{6mer} and forms a complex comprising one molecule of KaiC\textsubscript{6mer} and two molecules of KaiB\textsubscript{6mer} [17], as suggested by cryo-electron microscopy analysis [25]. We have proposed that the positively charged cleft (PC) of the KaiB\textsubscript{6mer} molecule, where the functionally important KaiB residues are concentrated, is an active site(s) required for interaction with KaiA and KaiC [24,28,39]. The PC of KaiB\textsubscript{6mer}, which is located on the dimer-dimer interface [24], is probably exposed by dissociation of KaiB\textsubscript{6mer} into dimers to interact with KaiC\textsubscript{6mer} [28,39], whereas the corresponding region of KaiB\textsubscript{1-94}, a dimeric mutant of KaiB, is always exposed [17]. Two areas on KaiC\textsubscript{6mer} molecule, on the other hand, are highly negatively charged—one around and inside the pore of KaiC\textsubscript{6mer} N-terminal domains and the other around the inter-subunit interface of one of two adjacent KaiC\textsubscript{6mer} N-terminal domains (Figures S1A and S1B) [37]. Interestingly, the ATP bound to the N-terminal ATPase motifs (namely, ATP-binding sites) is located adjacent to the latter.
area of KaiC (Figure S1B) [37]. Electrostatic interaction between the PC on KaiB and the aforementioned area of KaiC may allow sequestration of KaiB$_{4mer}$ (also KaiB$_{2mer}$ such as KaiB$_{1-94}$) and induce dissociation into dimers (temporal weak association). Then, the dissociation of two adjacent N-terminal domains in KaiC$_{6mer}$ resulting from the hydrolysis of ATP bound to the N-terminal ATPase motifs on one of the two adjacent subunits (Figures S1C and S1D), which pastes the two N-terminal domains each other [13, 32, 36, 37], may expose the latter area of KaiC—a possible KaiB-interacting surface—to KaiB$_{2mer}$, and electrostatic interaction between the PC on KaiB and the latter area of KaiC may result in the tight association of KaiB$_{2mer}$ with KaiC$_{6mer}$. The ATP bound to the N-terminal ATPase motifs inhibits the association of KaiB$_{4mer}$ with KaiC$_{6mer}$. The ATP bound to the N-terminal ATPase motifs on one of the two adjacent subunits (Figures S1C and S1D) may allow sequestration of KaiB$_{4mer}$ (also KaiB$_{2mer}$ such as KaiB$_{1-94}$) and induce dissociation into dimeric (temporal weak association). Then, the dissociation of two adjacent N-terminal domains in KaiC$_{6mer}$ resulting from the hydrolysis of ATP bound to the N-terminal ATPase motifs on one of the two adjacent subunits (Figures S1C and S1D), which pastes the two N-terminal domains each other [13, 32, 36, 37], may expose the latter area of KaiC—a possible KaiB-interacting surface—to KaiB$_{2mer}$, and electrostatic interaction between the PC on KaiB and the latter area of KaiC may result in the tight association of KaiB$_{2mer}$ with KaiC$_{6mer}$. The ATP bound to the N-terminal ATPase motifs inhibits the association of KaiB$_{4mer}$ with KaiC$_{6mer}$, which lack the autokinase activity (Figure 4E) [13], formed complexes with KaiB$_{1-94}$ (Figure 4D) indicated that the phosphorylated state of KaiC is not essential for KaiB-KaiC$_{6mer}$ complex formation. Our results are consistent with the recently reported results that KaiC$_{CatE2-6mer}$ formed a complex with KaiB$_{WT}$ [38]. The phosphorylation state of KaiC, therefore, is not directly involved in and essential for complex formation.

KaiC$_{AA-6mer}$ and KaiC$_{CatE2-6mer}$/AA, which did not form a complex with KaiB$_{1-94}$, showed much higher ATPase activity than any other KaiC ATPase motif mutants we examined (Figure 6 and Table S4). The excessively high ATPase activity of the N-terminal ATPase motifs of KaiC$_{AA-6mer}$, which bounces in and out of the ATP bound to the N-terminal ATPase motifs, may hinder formation of the KaiB-KaiC$_{6mer}$ complex. In KaiC$_{6mer}$, the phosphorylation state of the C-terminal domain could affect its association with KaiB via the N-terminal domain through modulating the N-terminal ATPase activity. However, we cannot exclude a possibility that KaiC$_{AA-6mer}$, which is likely not a perfect mimic for the fully unphosphorylated form of KaiC, might have a changed structure, which might enhance its ATPase activity but might reduce its association with KaiB. We propose the following model for ATP regulation of KaiB-KaiC interaction. The KaiC subunit is able to form a complex with
KaiB (Figure 7A). The N-terminal domains of KaiC6mer are partially dissociated (relaxed) when the ATP bound to the N-terminal ATPase motifs that pastes adjacent N-terminal domains each other in KaiC6mer is hydrolyzed (Figure 7B), which allows KaiB to associate with the KaiC6mer N-terminal domains. Then, KaiC6mer-associated KaiB suppresses the ATPase activity of KaiC6mer by inhibiting ATP binding to KaiC6mer N-terminal domains. KaiC6mer and KaiC6mer, which seem to mimic the unphosphorylation state of KaiC, have excessively high N-terminal ATPase activity (Figure 6 and Table S4), and that may cause rapid interconversion of the ridged (ATP-bound) and relaxed (ATP-hydrolyzed; ADP-bound or unbound) conformations of the N-terminal domains in KaiC6mer. We propose here that this rapid interconversion inhibits KaiB-KaiC6mer complex formation though we cannot explain this inhibiting mechanism at present (Figure 7C).

The C-terminal ATPase motifs of KaiC are involved in the hexamerization of KaiC C-terminal domains [13] as well as their inter-subunit autophosphorylation [8] and probably autodephosphorylation [12]. Although the KaiC N-terminal ATPase motifs are involved in the hexamerization of KaiC N-terminal domains [13], and the affinity of the N-terminal ATPase motifs for ATP is higher than that of its C-terminal ATPase motifs [13], and therefore, the N-terminal domains are likely to be more tightly connected than the C-terminal domains [13,16,29], the function of the N-terminal ATPase motifs remains unknown. In this investigation, we have succeeded in revealing that the nucleotide state of the N-terminal ATPase motifs regulates KaiB-KaiC interaction. Because KaiB and SasA competitively associate with KaiC via KaiC N-terminal domains [14,17], the nucleotide state also can regulate KaiC-SasA interaction via the KaiB-KaiC interaction. ATP acts not only as a biological fuel, but also as a physiological regulator. There are some examples for ATP regulation of the physiological function. Many different cell types release ATP in response to mechanical or biochemical stimulation, and the released ATP modulates cell function by activating nearby purinoceptors, such as ion channel P2X receptors and G-protein-coupled P2Y receptors [40-42].
Figure 7. ATP-mediated regulation model for KaiB-KaiC interaction. A. Interaction between KaiB and KaiC<sub>1mer</sub>. B. Partial dissociation (relaxation) of the N-terminal domain of KaiC<sub>6mer</sub> and complex formation of one KaiC<sub>6mer</sub> molecule with 2 KaiB<sub>2mer</sub> molecules. For simplification, we express Mg-chelated ATP and ADP as ATP and ADP. The nucleotide state of the C-terminal ATP-binding site (ATPase motifs) of KaiC<sub>6mer</sub> is not known. C. Rapid interconversion between the rigid ATP-bound and relaxed ATP-hydrolyzed form (ADP-bound or unbound) conformations in the N-terminal domains of KaiC<sub>6mer</sub>.
