---

**Background:** Polyphosphate (polyP) accumulates in an acidic calcium store named the acidocalcisome.

**Results:** TbVtc4 is an acidocalcisome polyP kinase required for osmoregulation and virulence.

**Conclusion:** TbVtc4 is a potential drug target in *T. brucei*

**Significance:** This is the first demonstration of an essential polyP kinase in trypanosomes.

---

Polyphosphate (polyP) is an anionic polymer of orthophosphate groups linked by high energy bonds that typically accumulate in acidic, calcium-rich organelles known as acidocalcisomes. PolyP synthesis in eukaryotes was unclear until it was demonstrated that the protein named Vtc4p (vacuolar transporter chaperone 4) is a long chain polyP kinase that localizes to the yeast vacuole. Here, we report that TbVtc4 (Vtc4 ortholog of *Trypanosoma brucei*) encodes, in contrast, a short chain polyP kinase that localizes to acidocalcisomes. The subcellular localization of TbVtc4 was demonstrated by fluorescence and electron microscopy of cell lines expressing TbVtc4 in its endogenous locus fused to an epitope tag and by purified polyclonal antibodies against TbVtc4. Recombinant TbVtc4 was expressed in bacteria, and polyP kinase activity was assayed *in vitro*. The *in vitro* growth of conditional knock-out bloodstream form trypanosomes (*TbVtc4-KO*) was significantly affected relative to the parental cell line. This mutant had reduced polyP kinase activity and short chain polyP content and was considerably less virulent in mice. The wild-type phenotype was recovered when an ectopic copy of the *TbVtc4* gene was expressed in the presence of doxycycline. The mutant also exhibited a defect in volume recovery under osmotic stress conditions *in vitro*, underscoring the relevance of polyP in osmoregulation.

---

Polyphosphate (polyP) is an inorganic polymer of orthophosphate (P_i) units linked by phosphoanhydride bonds. PolyP can exist as short (3 to ~300 P_i) or long chain (~300 to ~1,000 P_i) polymers, is abundant in nature, and has been conserved during evolution (1, 2). PolyP has been extensively studied in bacteria, where it is involved in several essential functions, such as DNA replication, sporulation, germination, motility, and pathogenesis. Much less is known of the functions of polyP in eukaryotes (1, 2). The recent discoveries that polyP can be released from some mammalian cells, such as blood platelets (3) and mast cells (4), and has potent modulatory activity on blood coagulation (5) and inflammation (6) have renewed interest in this polymer. Interestingly, polyP with chain lengths characteristic of microorganisms modulates coagulation and inflammation differently than polyP with chain lengths typically found in mammalian cells (7).

In many organisms, polyP is mobilized primarily by the synthetic activity of polyP kinases and degradation by endopoxopolyporphatases, respectively. A few genes encoding exopolyphosphatases (8–11) and endopolyphosphatases (12) have been described in eukaryotes. Recently, the first eukaryotic enzyme involved in synthesis and translocation of polyP, ScVtc4p (*Saccharomyces cerevisiae* vacuolar transporter chaperone 4), was identified (13). The Vtc complex consists of four proteins (Vtc1–4) that form hetero-oligomeric complexes and are able to synthesize and transfer polyP into the vacuole as well as impacting membrane trafficking and vacuole fusion (14–16). Vtc4 forms the catalytic core of the complex, although null mutations of each of the Vtc proteins result in reduced accumulation of polyP. Vtc proteins are present in fungi, algae, trypanosomatids, and Apicomplexan parasites but are absent in mammalian cells.

In many cells, short and long chain polyP accumulate in acidocalcisomes, acidic calcium stores (17) where polyP is complexed with several cations (18, 19). These organelles were first described in *Trypanosoma brucei* (20) but later identified in a broad range of organisms from bacterial to human cells (18) and are involved in Ca^{2+} signaling, as inferred from the presence in them of an inositol 1,4,5-trisphosphate receptor (21). *T. brucei* belongs to the group of trypanosomes that causes human African trypanosomiasis (also known as sleeping sickness), an endemic disease of Sub-Saharan Africa. There is no vaccine available for this disease, and chemotherapy also remains unsatisfactory, especially for advanced cases when a
An Essential Polyphosphate Kinase in T. brucei

neurological phase has been reached and the disease becomes potentially fatal.

Previous work has shown that polyP has a critical role in survival of trypanosomes under sharp environmental changes, including osmotic stress (22–24). This resistance to osmotic stress is essential for digenetic trypanosomatids as they encounter drastic osmotic changes in both the insect vectors and vertebrate hosts (23, 25, 26). Regulation of cell volume is, in addition, a homeostatic process needed at all times by all cells. PolyP hydrolysis occurs during hypsometric stress of trypanosomes (22), probably increasing the osmotic pressure of the acidoctalisomes and facilitating water movement. On the other hand, an increase in long chain polyP levels has been observed in T. cruzi during hyperosmotic stress (22, 23). This latter work suggested that polyP could play an important role at the early stages of hyperosmotic stress response by sequestering ions into the acidoctalisomes to reduce the ionic strength of the cytosol (23).

Homologs of S. cerevisiae Vtc1 and Vtc4 genes are present in the genome of T. brucei. TbVtc1, a protein present in T. brucei acidoctalisomes (27), is essential for polyP synthesis and acidoctalisome biogenesis. However, this protein does not have a polyP kinase domain or PPK activity. An ScVtc4p homolog (TbVtc4) was detected in a proteomic analysis of T. brucei acidoctalisomes.4 In the present study, we investigated the role of this enzyme by biochemical and genetic approaches, elucidating important aspects of its physiological role in T. brucei, where polyP seems to be essential for parasite survival in the mammalian host. Because Vtc4 proteins are absent in vertebrates, we propose this enzyme as a potential target for drug development and disease control.

EXPERIMENTAL PROCEDURES

Culture Methods—Cultivation of 29-13 procyclic form (PCF) (28) and single marker bloodstream form (BSF) (29) trypanosomes derived from T. brucei Lister strain 427 was carried out as described previously (30). Cell growth was followed using a Beckman® Coulter Z1 dual cell and particle counter.

Chemicals and Reagents—TREZol reagent, MagicMedia, Taq polymerase, BenchMark protein ladder, Alexa-conjugated secondary antibodies, and Escherichia coli BL21 Codon Plus (DE3)-RIPL were purchased from Invitrogen. Vector pET32 Eκ/LIC, Benzonase® nuclease, anti-histidine tag antibodies, and S-protein HRP conjugate were from Novagen (EMD Millipore, Billerica, MA). [α−32P]dCTP (3,000 Ci/mmol) and [γ−32P]ATP (3,000 Ci/mmol) were from PerkinElmer Life Sciences. Rabbit and mouse antibodies against T. brucei vacuolar H+ -pyrophosphatase (TbVp1) (31) were a gift from Dr. Norbert Bakalara (Ecole Nationale Supérieure de Chimie de Montpellier, Montpellier, France). Anti-HA high affinity rat monoclonal antibody (clone 3F10) was purchased from Roche Applied Science. The pMOTag4H vector (32) was a gift from Dr. Thomas Seebeck (University of Bern, Bern, Switzerland). PD-10 desalting columns were from GE Healthcare. Pierce ECL Western blotting substrate and Pierce BCA protein assay reagent were from Thermo Fisher Scientific Inc. Zeta-Probe GT genomic testing blotting and nitrocellulose membranes were from Bio-Rad. The AMAXA human T-cell Nucleofector kit was purchased from Lonza (Germany). The Prime-a-Gene labeling system was from Promega (Madison, WI). QIAprep Spin Mini-prep and Midiprep kits, the QIAquick gel extraction kit, and the MiniElute PCR purification kit were from Qiagen (Valencia, CA). The fluorimetric ADP assay kit was from PhosphoWorks (AAT Bioquest, Inc., Sunnyvale, CA). The primers were purchased from Integrated DNA Technologies (Coralville, IA). Antibiotics and all other reagents of analytical grade were from Sigma.

Sequence Analysis—The analysis of TbVtc4 sequence (gene ID Tbi11.01.4040) was performed using DNAMAN software (version 7.212, Lynnon Corp., Quebec, Canada) for alignments, BLAST for searching homologous sequences, the Motif Scan algorithm for prediction of functional domains (33), and the TopPred algorithm for the prediction of transmembrane domains (34). General information available for this sequence was obtained from TriTrypDB (35).

Gene Cloning and Protein Heterologous Expression—DNA sequence corresponding to the TbVtc4 catalytic core (nucleotides 595–1518 of the TbVtc4 open reading frame, amino acids 199–506 of the full-length protein) was PCR-amplified from T. brucei 29-13 strain gDNA (forward primer, 5′-GAGGAGCAAGATACCTTGTTGACCGTTGG-3′; reverse primer, 5′-GAGGAGAACCCGGGTGTGGAAAGCCGGAATGTCCA-3′) and ligation-independently cloned into vector pET32 Eκ/LIC for heterologous expression in bacteria. The sequence of several recombinant clones was verified, and they were transformed by heat shock into E. coli BL21 Codon Plus (DE3)-RIPL chemically competent cells. Induction of TbVtc4 (199–506) expression was performed with MagicMedia following the manufacturer’s dual temperature protocol to avoid aggregation of protein in inclusion bodies for purification under native conditions. Protein expression was alternatively induced with 1 mM isopropyl-β-D-thiogalactopyranoside in LB broth for 3 h at 37 °C for purification under denaturing conditions.

The catalytic domain of ScVtc4p (aa 189–480 (13)) was amplified by yeast gDNA using standard PCR protocols (forward primer, 5′-GAGCTCAAGGGAAGCAACAAAATTTC-3′; reverse primer, 5′-CAGGTGTCATTGAGGTAACCAAA-3′) and Pfu Ultra HF (Stratagene). The fragment was cloned with a TOPO-TA cloning kit, verified by sequencing, and ligated into the expression vector pQE-2 (Qiagen) using Sacl and Pml sites that were added to the 5′- and 3′-primers, respectively. E. coli (BL21 Codon Plus DE3 RIPL, Stratagene) were transformed with ScVtc4p (189–480)/pQE-2. Histidine-tagged ScVtc4p (189–480) was induced overnight at 25 °C with 0.5 mM isopropyl-β-D-thiogalactopyranoside, isolated by metal ion affinity chromatography, and desalted on a HiTrap column (GE Healthcare) with 25 mm Tris, 200 mM NaCl, 2 mM DTT (13).

Purification of Recombinant TbVtc4 Catalytic Core under Native Conditions—Cell pellets from a 200-ml culture of recombinant E. coli BL21 expressing TbVtc4 (199–506) grown in MagicMedia were resuspended and incubated for 30 min on

4G. Huang, P. N. Ulrich, D. Johnson, S. N. J. Moreno, R. Orlando, and R. Docampo, unpublished data.
ice in 20 ml of cold lysis buffer: 50 mM sodium phosphate, pH 8.0, 0.3 M sodium chloride, 10 mM imidazole, 0.1% Triton X-100, 0.1 mg/ml lysozyme, 25 units/ml Benzonase® nuclease and protease inhibitor mixture for purification of histidine-tagged proteins (Sigma; 50 μg/g of cell paste). Then three sonication pulses (40% amplitude, 30 s, on ice) were applied to ensure the complete disruption of cells. After centrifugation at 20,000 × g for 30 min at 4 °C, supernatant was passed through a 0.8-μm pore nitrocellulose filter in order to obtain a clarified crude protein extract that was kept on ice and used for immediate purification of recombinant TbVtc4(199–506). Protein purification was performed at 4 °C using HIS-Select® Cartridge (Sigma), in an immobilized nickel-ion affinity chromatography system, following the manufacturer’s protocol for histidine-tagged protein purification under native conditions. One-ml fractions were eluted (elution buffer: 50 mM sodium phosphate, pH 8.0, 0.3 M sodium chloride, 250 mM imidazole), and buffer exchange was performed immediately using PD-10 desalting columns to finally obtain the protein in assay buffer (20 mM Hepes, pH 6.5). All purification steps were verified by SDS-PAGE and Western blot analyses using anti-histidine tag commercial antibodies or S-protein HRP conjugate. For antibody production, recombinant TbVtc4(199–506) was purified under denaturing conditions using HIS-Select® affinity mAb (Roche Applied Science; diluted 1:10) and polyclonal anti-TbVtc4 antibodies were produced in mice using the monoclonal antibody against HA and anti-rabbit gold-conjugated as a secondary antibody. Mouse anti-TbVP1 polyclonal antibodies and anti-mouse gold-conjugated secondary antibodies were used.

Antibody Production—Polyclonal anti-TbVtc4 antibodies were generated in a guinea pig by Covance (Princeton, NJ) against a synthetic peptide (CSRSRRVYARRKIRYDDDRG) that corresponds to a conserved hydrophilic region located between the second and the third predicted transmembrane domains of the TbVtc4 amino acid sequence. In addition, polyclonal anti-TbVtc4 antibodies were produced in mice using recombinant TbVtc4(199–506) as an antigen. These antibodies were generated at the Monoclonal Antibody Facility of the College of Veterinary Medicine, University of Georgia (Athens, GA). Final bleeds from five inoculated mice were affinity-purified by immunoadsorption to the recombinant protein immobilized on nitrocellulose strips. The adsorbed antibodies were eluted with 0.1 M glycine, pH 2.5, and neutral pH was restored immediately by adding 1 M Tris-HCl buffer, pH 8.0.

Fluorescence Microscopy—For immunofluorescence assays, T. brucei PCF trypanosomes were centrifuged at 1,000 × g for 10 min at 25 °C; washed twice with PBS, pH 7.4; and fixed with 4% paraformaldehyde in PBS for 1 h on ice. Afterward, cells were adhered to poly-L-lysine-coated coverslips; permeabilized with 0.3% Triton X-100 for 3 min; washed three times; and blocked with PBS containing 3% BSA, 1% fish gelatin, 50 mM NH₄Cl, and 5% goat serum for 1 h. Next, cells were incubated for 1 h at room temperature with primary antibodies: polyclonal guinea pig anti-TbVtc4 (1:50) or rat anti-HA tag high affinity mAb (Roche Applied Science; diluted 1:10) and polyclonal rabbit anti-TbVP1 (1:250), as acidocalscione marker. After washing three times with 3% BSA in PBS (pH 8.0), cells were incubated for 45 min at room temperature in the dark with secondary antibodies: Alexa Fluor 488-conjugated goat anti-guinea pig or anti-rabbit (1:1,000) and Alexa Fluor 546-conjugated goat anti-rabbit or anti-mouse (1:1,500). Then, cells were counterstained with 5 μg/ml DAPI to label nuclei and kineto-plast (mitochondrial DNA). Finally, all preparations were washed again three times with 3% BSA in PBS (pH 8.0) and mounted on glass slides with Fluoromount-G (Southern Biotechnology). Differential interference contrast and fluorescence optical images were captured under non-saturating conditions and identical exposure times using an Olympus IX-71 inverted fluorescence microscope with a Photometric Cool-SnapHQ charge-coupled device (CCD) camera driven by DeltaVision software (Applied Precision).

Electron Microscopy—BSF trypanosomes were washed twice in 0.1 M sodium cacodylate buffer, pH 7.4, and fixed for 1 h on ice with 0.1% glutaraldehyde, 4% paraformaldehyde, and 0.1 M sodium cacodylate buffer, pH 7.4. Samples were processed for cryo-immunoelectron microscopy at the Molecular Microbiology Imaging Facility, Washington University School of Medicine, CA. HA fusion protein localization was detected with a polyclonal antibody against HA and anti-rabbit gold-conjugated as a secondary antibody. Mouse anti-TbVP1 polyclonal antibodies and anti-mouse gold-conjugated secondary antibodies were used.

Enzymatic Assays for PolyP Synthesis—ADP Assay—For determination of TbVtc4 and ScVtc4p kinetic parameters, the specific activity of the enzyme was assayed using an ADP determination kit (PhosphoWorks™ fluorimetric ADP assay kit, AAT Bioquest, Inc.) to quantify the amount of ADP or GDP synthesized during polyP polymerization at different ATP or GTP concentrations. Analysis of ATP conversion by the recombinant catalytic domain of ScVtc4p was carried out in buffer containing 50 mM Tris–HCl (pH 7.5), 150 mM NaCl, 1 mM MnCl₂, and 1 mM ATP, at room temperature using 1 μM ScVtc4p. TbVtc4 polyP kinase activity was assayed in buffer containing 50 mM Hepes (pH 6.5), 150 mM NaCl, and 1 mM ATP, at room temperature using 1 μM TbVtc4 and 1 mM ATP or different concentrations of ATP or GTP. When indicated, 1 mM P₁ was included in the reactions. Twenty-μl reactions were incubated 1 h at room temperature. Components A and B of the ADP/GDP determination kit were added immediately, and after a 30-min incubation at room temperature, fluorescence was detected at a 540/590-nm excitation/emission ratio in a Molecular Devices plate reader. An ADP (or GDP) standard curve was obtained for quantification purposes. The data were fit to a Michaelis-Menten equation, and GraphPad Prism software version 5.0 was used for data analysis and determination of Kₘ, Vₘₐₓ, and kᵦₜ.

Coupled Assay—ATP hydrolysis was also monitored via NADH oxidation enzymatically coupled to the phosphorolysis of produced ADP. NADH concentration was measured optically at 340 nm in buffer containing 150 μM NADH, 0.15 mM phosphoenolpyruvate, 0.1 mg/ml pyruvate kinase, and 0.1 mg/ml lactate dehydrogenase. The reaction was initiated by the addition of 1 mM ATP, and the incubations were done under the same conditions described above.

Radioactive Assay—To visualize TbVtc4 and ScVtc4p reaction products, newly synthesized polyP chains were detected by autoradiography using [γ³²P]ATP as substrate. Polyp was separated by electrophoresis on Tris borate-EDTA (TBE)-polyacrylamide gels. Reactions were carried out as described above using 1 mM [γ³²P]ATP (20 Ci/mmol) in a final volume of 50 μl
An Essential Polyphosphate Kinase in T. brucei

for 8 h at room temperature and stopped by adding EDTA (final concentration = 1 mM) and 10× sample buffer (2 mg/ml Orange G, 30% glycerol). Before loading the samples, TBE-polyacrylamide gels (0.1 × 16 × 20 cm, 1× TBE, 10% polyacrylamide (19:1 acrylamide/bisacrylamide), 0.05% tetramethyldiamine, 0.05% (w/w) ammonium persulfate) were prerun at 200 V for 30 min in a cold room using a PROTEAN® II xi Cell (Bio-Rad). Thirty μl of sample and commercial polyP markers were loaded per well as indicated. Gels were run with a 4-mA constant current for 20 h at 4 °C. Different pH and cation requirements were assayed. Dried gels were exposed to films for at least 48 h at −80 °C for autoradiography.

Molecular Constructs for TbVtc4 Mutant Cell Lines—For TbVtc4 knock-out construction in BSF trypomastigones, one TbVtc4 allele was knocked out by replacement with a puromycin selectable marker in the single marker line that expresses T7 polymerase and tetracycline repressor maintained by a single G418 resistance marker (29). This puromycin cassette was obtained by PCR using a set of long primers (ultramers) containing 100–120 nucleotides from the 5′- and 3′-UTRs flanking regions of the TbVtc4 ORF (forward primer, 5′-GCTGTGTTGTTTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) and reverse primer, 5′-GTTAAAACATAGCAGAACATCAGCACATTACTGACAATCAACCAACATGT-3′ containing 100–120 nucleotides from the 5′-UTRs flanking TbVtc4 ORF 5′- and 3′-UTRs (forward primer, 5′-GACGACGACAAGATACCTTGTGGTACCGTCTGCTCCTCGGCCA-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) and pMOTag23M vector as template (32). To replace the second allele, we first introduced an ectopic copy of the gene (TbVtc4ec) under the control of the tetracycline-inducible promoter and selectable by blasticidin resistance inserted at the ribosomal non-transcribed spacer. This cassette was constructed, amplifying the TbVtc4 gene by PCR from T. brucei single marker strain gDNA (forward primer, 5′-CAGTATGCTATGCCCCCTCACGAAAACATG-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) into pLEW100 vector into pLEW100v5b1d-BSD expression vector (a gift from Dr. George Cross, The Rockefeller University, New York), a modified version of the original pLEW100 vector (29). The construct was linearized with NotI restriction enzyme before cell transfection. Finally, the second TbVtc4 allele was knocked out by replacement with a plasmid selectable marker while keeping the ectopic copy “on” by the addition of tetracycline to the selection medium. The plasmid cassette was also PCR-amplified using a primer set containing 100–120 nucleotides from TbVtc4 ORF 5′- and 3′-UTRs (forward primer, 5′-GCTGTGTTGTTTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′; reverse primer, 5′-GTTAAAACATAGCAGAACATCAGCACATTACTGACAATCAACCAACATGT-3′) to clone TbVtc4ec into pLEW100v5b1d-BSD expression vector and pMOTag23M vector as template (32). To replace the second allele, we first introduced an ectopic copy of the gene (TbVtc4ec) under the control of the tetracycline-inducible promoter and selectable by puromycin resistance inserted at the ribosomal non-transcribed spacer. This cassette was constructed, amplifying the TbVtc4 gene by PCR from T. brucei single marker strain gDNA (forward primer, 5′-CAGTATGCTATGCCCCCTCACGAAAACATG-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) and pMOTag23M vector as template (32). To replace the second allele, we first introduced an ectopic copy of the gene (TbVtc4ec) under the control of the tetracycline-inducible promoter and selectable by puromycin resistance inserted at the ribosomal non-transcribed spacer. This cassette was constructed, amplifying the TbVtc4 gene by PCR from T. brucei single marker strain gDNA (forward primer, 5′-CAGTATGCTATGCCCCCTCACGAAAACATG-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) and pMOTag23M vector as template (32). To replace the second allele, we first introduced an ectopic copy of the gene (TbVtc4ec) under the control of the tetracycline-inducible promoter and selectable by puromycin resistance inserted at the ribosomal non-transcribed spacer. This cassette was constructed, amplifying the TbVtc4 gene by PCR from T. brucei single marker strain gDNA (forward primer, 5′-CAGTATGCTATGCCCCCTCACGAAAACATG-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′) and pMOTag23M vector as template (32).

Southern Blot Analysis—Genomic DNA from parental and TbVtc4 mutant cell lines was extracted as described (36). Two μg of gDNA were digested overnight with BamHI and HindIII restriction enzymes. Digestion products were resolved by electrophoresis on a 1% agarose gel in Tris-acetate EDTA buffer at 50 V. DNA was transferred from agarose gels onto Zeta-Probe blotting membranes (Bio-Rad) by capillarity overnight using 0.4 M NaOH as transfer solution. Membranes were hybridized and radiolabeled TbVtc4 probe, generated by PCR (forward primer, 5′-AGGAGGAAAGCTCCCTCTTGGTGACTGCCGCTCTAGTGGAT-3′; reverse primer, 5′-AGATGATCATCAGAAGGTGTCGCTTCCGGAGGCTCTTATATTTCCTGCCCCTCCCTCAGTCTGGCGGCCGCTCTAGAACTAGTGGAT-3′), and labeled with [α-32P]dCTP using random hexanucleotide primers and the Klenow fragment of DNA polymerase I (Prime-a-Gen labeling system, Promega). Membranes were exposed to films for 24–72 h at −80 °C and developed in a dark room.
Northern Blot Analysis—Northern blot analysis was performed as described previously (23). Briefly, total RNA was isolated from BSF using TRI Reagent®. RNA samples were subjected to electrophoresis in 1% agarose gels containing 2.2 M formaldehyde, 20 mM MOPS, pH 7.0, 1 mM EDTA, and 8 mM sodium acetate, transferred to nylon membranes, and hybridized with radiolabeled probes for TbVtc4 and the Tb-ß-tubulin gene (Tb927.1.2390). Tb-ß-tubulin probe was also generated by PCR (forward primer, 5'-TGCCTGAGATTGTGTCGTT-AGG-3'; reverse primer, 5'-AGTGCAGACGAGGAAGGCAGC-ACCA-3') and labeled with [α-32P]dCTP using random hexanucleotide primers and the Klenow fragment of DNA polymerase I (Prime-a-Gene labeling system, Promega). The Tb-ß-tubulin gene was used as a loading control, assuming a similar level of expression of this gene in all mutants at the same stage. Finally, membranes were exposed to films for 24–72 h at −80 °C and developed in a dark room.

Western Blot Analysis—Parental and mutant cell lines were separately harvested. Parasites were washed twice in PBS (PCF) or buffer A containing glucose (BAG; 116 mM NaCl, 5.4 mM KCl, 0.8 mM MgSO4, 50 mM HEPES, and 5.5 mM glucose, pH 7.3) for BSF and resuspended in radioimmune precipitation assay buffer (150 mM NaCl, 20 mM Tris-HCl, pH 7.5, 1 mM EDTA, 1% SDS, and 0.1% Triton X-100) plus protease inhibitors (mammalian cell protease inhibitor mixture (Sigma P8340, diluted 1:250), 1 mM EDTA, 1 mM PMSF, 2.5 mM tosylphenylalanyl chloromethyl ketone and 100 μM E64) and Benzonase® nuclease (25 units/ml of culture). Then cells were incubated for 30 min on ice, and five rounds of freeze-thaw were applied (5 min on dry ice/ethanol bath, 1 min on 37 °C water bath). Cell lysis was verified under a light microscope, and protein concentration was determined by a BCA protein assay (Pierce). Thirty micrograms of protein from each cell lysate were mixed with 4× Laemmli sample buffer and analyzed by SDS-PAGE in 10% gels. Separated proteins were transferred onto nitrocellulose membranes (Bio-Rad) using a Bio-Rad transblot apparatus. Membranes were blocked with 5% nonfat dried skim milk in PBST (PBS containing 0.1% (v/v) Tween 20) overnight at 4 °C. Next, blots were incubated for 1 h at room temperature with different primary antibodies: polyclonal mouse anti-TbVtc4 (1:500), rat anti-HA tag mAb (1:100), or anti-tubulin mAb (1:50,000). After five washes with PBST, blots were incubated with the appropriate secondary antibody: HRP-conjugated goat anti-mouse or anti-rat IgG (1:15,000) for 1 h at room temperature. After washing five times with PBST, the immunoblots were visualized using ECL Western blotting substrate (Pierce) according to the manufacturer’s instructions.

Short Chain and Long Chain Polyphosphate Quantification—Determination of polyP levels in BSF parental and mutant cell lines was performed as described previously by measuring P, release by recombinant yeast expolysphatase (37).

Regulatory Volume Changes under Osmotic Stress Conditions—For osmotic stress under constant ionic strength, the following buffers described previously (37, 38) with some modifications were used: isotonic (64 mM NaCl, 4 mM KCl, 1.8 mM CaCl2, 0.53 mM MgCl2, 5.5 mM glucose, 5 mM Na-Hepes, pH 7.4, and 150 mM mannitol; 320 ± 5 mosm, as determined using an Advanced Instruments 3D3 osmometer), hypotonic (the same as isotonic but without mannitol; 160 ± 5 mosm), and hypertonic (the same as isotonic but with increased mannitol concentration to 1.2 M; 980 ± 5 mosm). Samples of 1 × 10⁷ BSF (single marker strain and TbVtc4-KO with or without tetracycline) were collected, washed with isotonic buffer prewarmed at 37 °C, and resuspended in 100 μl of isotonic buffer. Next, cells were transferred to a 96-well plate, and changes in cell volume were followed using a plate reader at 550 nm in a plate reader with continuous agitation to avoid decantation of parasites. Osmotic stress was induced after 3 min of absorbance recording as follows. Hyposmotic stress was induced by the addition of 200 μl of hypotonic buffer to 100 μl of cells in isotonic buffer (final osmolarity, 213 mosm), hyperosmotic stress was induced by the addition of 100 μl of hypertonic buffer to 100 μl of cells in isotonic buffer (final osmolality, 650 mosm), and controls adding 100 and 200 μl of isotonic buffer to the cells were carried out in parallel. After inducing osmotic stress, absorbance at 550 nm was recorded for an additional 10 min. Cell viability was verified in the microscope after 10 min under osmotic stress.

In Vivo Studies—To evaluate the infectivity of TbVtc4-KO BSF trypanosomes, the cells were cultivated for 14 days in the absence of tetracycline. Exponentially growing cells (single marker and TbVtc4-KO with or without tetracycline) were washed once in HMI-9 medium without selectable drugs and resuspended in the same medium. Eight-week-old BALB/c mice (5 mice/group) were infected with a single intraperitoneal injection of 2 × 10⁴ BSF trypanosomes in 0.2 ml of HMI-9 medium. Mice were given either normal water or water containing 200 μg/ml doxycycline in a 5% sucrose solution (30, 31). The drinking water with or without doxycycline was provided 3 days before infection and exchanged every 2–3 days, continuing throughout the 30-day period. Animals were fed ad libitum on standard chow. Parasitemia levels were monitored 1–2 times/week during the whole experiment (39). Mice were euthanized upon attaining a parasite density over 1 × 10⁸ cells/ml. This study was carried out in strict accordance with the recommendations in the National Institutes of Health Guide for the Care and Use of Laboratory Animals. The animal protocol was approved by the Institutional Animal Care and Use Committee of the University of Georgia.

Statistical Analyses—For all experiments, results were expressed as mean values of three independent experiments ± S.D. Statistical analyses were performed using GraphPad Prism software version 5.0. Comparison of polyP kinase activity and short and long chain polyP content in different cell lines was performed by Student’s t test with a significance level of 0.05. Comparison of changes in cell volume after osmotic stress in different cell lines was done by Bonferroni’s multiple comparison a posteriori test of one-way analysis of variance at all time points after induction of osmotic stress (significance level = 0.05). In this way, the pattern of response to osmotic stress of all cell lines was analyzed during the entire period of observation.

RESULTS

TbVtc4 Sequence Analysis—The TbVtc4 amino acid sequence (NCBI Reference Sequence: XP_829284.1; TriTrypDB sequence: Tb11.01.4040) was aligned with orthologs from other kinetoplastids and also with ScVtc4p (not shown). TbVtc4 sequence shares
TbVtc4 Synthesizes Short Chain PolyP and Requires Divalent Cations but Not Pyrophosphate—To characterize the enzymatic activity of TbVtc4, we expressed its catalytic domain (TbVtc4(199–506)) as a fusion protein with an N-terminal polyhistidine tag. We tested the activity of TbVtc4 with ATP or GTP (Fig. 3, A and B, respectively). ScVtc4p was assayed with ATP in the absence and presence of PPi (Fig. 3, C and D, respectively). TbVtc4 has a higher affinity for ATP than ScVtc4p (Table 1) in the absence of PPi, \( (TbVtc4 \ K_m = 54.8 \pm 7.3 \ \mu M \text{ versus } ScVtc4p \ K_m = 261.2 \pm 48.6 \ \mu M) \). However, the yeast enzyme is much more efficient than TbVtc4 (ScVtc4p \( k_{cat}/K_m = 9.3 \times 10^3 \ \text{s}^{-1} \text{ M}^{-1} \) versus TbVtc4 \( k_{cat}/K_m = 3.1 \times 10^3 \ \text{s}^{-1} \text{ M}^{-1} \)). The presence of PPi did not “prime” or stimulate TbVtc4 activity (see also Fig. 3C), as was observed with the yeast enzyme (13). On the other hand, the reported priming effect of PPi on the polyP kinase activity of ScVtc4p was confirmed by the increase in its efficiency in the presence of PPi, with a \( k_{cat}/K_m \) ratio of \( 1.7 \times 10^4 \ \text{s}^{-1} \text{ M}^{-1} \) (Table 1).

PolyP produced by TbVtc4 reactions was visualized using \( [\gamma-32P]ATP \) as substrate followed by TBE-PAGE. TbVtc4 requires divalent cations, preferentially \( \text{Mg}^{2+} \), \( \text{Mn}^{2+} \), or \( \text{Zn}^{2+} \) (Fig. 3, A and D) and an acidic pH (Fig. 3, B and E) for optimal
activity. The increased activity of TbVtc4 at acidic pH was corroborated using a different method based on a coupled assay that generates NADH upon polyP production. In contrast to TbVtc4 (optimal pH = 6.0), ScVtc4p exhibited pH optima at 6.0 and 7.5 (Fig. 3F). Finally, TBE-PAGE/autoradiography demonstrated that polyP chains synthesized by TbVtc4 catalytic core are much shorter (−100–300 Pi residues) than those produced by ScVtc4p (−750 Pi residues) (Fig. 3C), and TbVtc4 activity was inhibited in the presence of PPi (Fig. 3C).

Reduced Expression of TbVtc4 in BSF Trypanosomes Results in Decreased PolyP Kinase Activity and Short Chain PolyP Content—Previous studies demonstrated that polyP is important for trypanosome growth and osmoregulation in trypanosomes (22, 23, 27, 30, 31, 37), but the length of the polyP responsible for these roles was not investigated. To investigate whether the short chain polyP synthesized by TbVtc4 is involved in these processes, we analyzed the phenotypic changes of BSF trypanosomes (22, 23, 27, 30, 31, 37), but the length of the polyP responsible for trypanosome growth and osmoregulation in trypanosomes (22, 23, 27, 30, 31, 37), but the length of the polyP responsible for these roles was not investigated. To investigate whether the short chain polyP synthesized by TbVtc4 is involved in these processes, we analyzed the phenotypic changes of BSF trypanosomes with a conditional KO of TbVtc4. In these cells, we replaced both TbVtc4 alleles with drug resistance genes, but, because TbVtc4 could be required for growth, we introduced an ectopic copy of the TbVtc4 gene whose expression depended on the presence of tetracycline or doxycycline in the culture medium (Fig. 4A). The genotype of the mutant cell line was verified by Southern blot analysis (Fig. 4B). Levels of mRNA in the presence or absence of tetracycline were analyzed by Northern blot (Fig. 4C). As expected, there was a decrease in TbVtc4 mRNA levels in the absence of tetracycline for the KO cell line. In the presence of tetracycline, TbVtc4 mRNA levels of the KO mutant were normal because of the ectopic gene expression. The expression level of TbVtc4 in these mutants was confirmed by Western blot analysis using mouse polyclonal antibodies against TbVtc4 (Fig. 4D).

The in vitro growth rate of the mutant cell line in the absence of tetracycline was monitored during 2 weeks and compared with that of the parental single marker strain (WT). The growth rate of TbVtc4-KO BSF progressively decreased relative to the parental cell line. TbVtc4-KO BSF partially recovered as escape mutants arose after 14 days (Fig. 5A). PolyP kinase activity after 2 weeks of withdrawal of tetracycline was significantly decreased in total cell lysates (Fig. 5B). Reduced activity was accompanied by a 35% decrease in short chain polyP (Fig. 5C) but no significant changes in long chain polyP levels (Fig. 5D). In summary, our results indicate that disruption of TbVtc4 in BSF trypanosomes decreases polyP kinase activity and, as a consequence, results in significantly lower levels of short chain polyP.

TbVtc4-KO Mutant Parasites Display an Osmoregulatory Defect—To investigate the role of TbVtc4 in osmoregulation, we exposed TbVtc4-deficient BSF trypanosomes to hypotonic and hyperosmotic conditions and evaluated changes of

In summary, our results indicate that disruption of TbVtc4 in BSF trypanosomes decreases polyP kinase activity and, as a consequence, results in significantly lower levels of short chain polyP.

**An Essential Polyphosphate Kinase in T. brucei**

![Image](https://example.com/image.png)
cell volume with time. These parasites showed a defect in the ability to recover cell volume (a process known as regulatory volume decrease (41)) during hyposmotic stress when compared with parental (WT) and complemented (H11001 tet) cell lines (Fig. 6A). Loss of water was also more pronounced in these parasites during hyperosmotic treatment compared with the single marker cell line. This defect in hyperosmotic response was overcome when we induced the expression of an ectopic copy of the gene (Fig. 6B).

**TbVtc4 Is Required for Effective in Vivo Infection**—We tested the infectivity of the *TbVtc4*-KO mutants in vivo using a mouse model, and we found that the mutant cells were considerably less virulent in mice (Fig. 6A). Loss of water was also more pronounced in these parasites during hyperosmotic treatment compared with the single marker cell line. This defect in hyperosmotic response was overcome when we induced the expression of an ectopic copy of the gene (Fig. 6B).

*TbVtc4* Is Required for Effective in Vivo Infection—We tested the infectivity of the *TbVtc4*-KO mutants in vivo using a mouse model, and we found that the mutant cells were considerably less virulent in mice. Once again, the phenotype reverted when we induced the expression of an ectopic copy of the gene (Fig. 6B).

**DISCUSSION**

We report here that *TbVtc4* encodes a short chain polyP kinase that localizes to the acidocalcisomes of *T. brucei*. The enzyme is important for osmoregulation, in vitro growth, and infectivity of BSF trypanosomes in vivo.

In contrast to the *S. cerevisiae* enzyme, which is a very long chain polyP kinase, *TbVtc4* catalyzes production of polyP of about 100–300 P\(_i\) units and was not activated but rather inhibited by PP\(_i\). Despite these differences, we found some charac-

FIGURE 4. Generation of TbVtc4 cKO cell line. A, schematic representation of the strategy used for the generation of a stable TbVtc4 conditional knock-out mutant in T. brucei BSF. i, one allele of TbVtc4 was replaced with the puromycin resistance gene (PAC) by homologous recombination, generating the TbVtc4 SKO cell line. ii, an ectopic TbVtc4 cassette under the control of the tetracycline-inducible PARP promoter and selectable by blasticidin resistance (BSD) was inserted at the ribosomal non-transcribed spacer (rDNA), generating the TbVtc4 cSKO cell line. This cassette was constructed using pLEW100v5b1d-BSD expression vector. iii, while keeping induced the expression of the ectopic TbVtc4, the second allele of the gene was replaced with a phleomycin resistance gene (PHLEO) by homologous recombination, resulting in conditional knock-out cell line TbVtc4 cKO. B, Southern blot analysis of parental cell line (single marker; WT), overexpressing (OE), single knock-out (SKO), complemented single knock-out (cSKO), and complemented double KO (cKO). C, Northern blot analysis of WT and TbVtc4-KO mutant (cKO) in the absence or presence of tetracycline (+ Tet), using a Vtc4 probe. A tubulin probe was used as a loading control. D, Western blot analysis of TbVtc4 cKO mutant cell line in the absence or presence of tetracycline, using polyclonal antibodies anti-TbVtc4 and anti-tubulin antibodies as a loading control. Affinity-purified recombinant TbVtc4 (199–506) (rTbVtc4) was included as control. Molecular weights are shown to the left of the blot.

Characteristics of the enzyme similar to those of ScVtc4p (13). Bivalent cation requirements for both enzymes are slightly different (TbVtc4 metal ion specificity is Mg$^{2+} > $Mn$^{2+} > $Zn$^{2+} > Co$^{2+} > $Fe$^{2+} > $Ni$^{2+} > $Ca$^{2+}$, and ScVtc4p metal ion specificity is Mn$^{2+} > $Zn$^{2+} > $Co$^{2+} > $Mg$^{2+} > $Fe$^{2+} > $Ni$^{2+}$). It is important to mention that the acidocalcisome environment of TbVtc4 is rich in zinc, magnesium, and calcium (42). Both enzymes can catalyze polyP synthesis at acidic pH. TbVtc4 activity is highest at a pH of 6.0, but ScVtc4p exhibits two optimal pH values (6.0 and 7.5). Although these enzymes are located in the membrane of acidic calcium stores (the acidocalcisome and the yeast vacuole, respectively), their catalytic domains are facing the cytosol. It is possible that the microenvironment close to the outer leaflet of the acidocalcisome and vacuolar membranes has a lower pH due to the presence of Na$^{+}$/H$^{+}$ exchangers that move protons out from the acidocalcisome (40) and vacuole lumen (43).

A significant decrease in the level of short chain polyP was observed in the knock-out BSF trypanosomes. However, a large reservoir was still present after parasites had been cultured for 2 weeks without tetracycline. The persistence of short chain polyP could be due to the known slow turnover of polyP (44) but more likely arises from the methodological limitations in distinguishing between abundant forms of very short polyP (polyP$_{1}$, polyP$_{2}$, and polyP$_{3}$) (45) and medium size polyP (100–300 P$_{1}$), which are the main product of TbVtc4. The synthetic mechanism of very short polyP is unknown. Nevertheless, our results suggest that medium size polyP is important for osmoregulation and viability. Although previous reports have shown that polyP has important roles in growth and osmoregulation in trypanosomes (22, 23, 27, 30, 31, 37), the length of the polyP responsible for these roles was not investigated. In this work, we report that polyP of 100–300 P$_{1}$ units, which is synthesized by TbVtc4, is required for regulatory volume decrease during hypotonic stress and also relevant for the response of the parasites to hyperosmotic stress conditions. The ability of these parasites to overcome such drastic changes in osmolarity is critical from their survival in the mammalian host. BSF trypanosomes in humans must be able to resist osmolality as high as 1,400 mosm when passing through the renal medulla and rapidly accommodate a return to the isosmotic environment (300 mosm) of the general circulation (46). Our results demonstrate that depletion of TbVtc4 in BSF trypanosomes leads to defective osmoregulation and infectivity. Both phenotypes are rescued with expression of an ectopic copy of the gene. A possible explanation for these observations is that mutant parasites, with lower short chain polyP levels, are not able to overcome...

FIGURE 5. Effect of inhibition of TbVtc4 expression on cell growth, polyP kinase activity, and short and long chain polyP levels. A, in vitro growth of single marker BSF (WT, full circles, blue) and TbVtc4 conditional knock-out parasites (TbVtc4 KO, full squares, red). B, lysates from TbVtc4-KO BSF showed an 8-fold lower polyP kinase activity than those from single marker BSF trypanosomes (WT). C and D, extracts from TbVtc4-KO BSF trypanosomes showed a 35% reduction in short chain polyP content (C) with no significant changes in long chain polyP content (D), as compared with the parental cell line (WT). Values are means ± S.D. (error bars) of three different experiments. *, differences are statistically significant as compared with respective controls, p < 0.05 (Student’s t test).

FIGURE 6. Effect of inhibition of TbVtc4 expression on the response of BSF trypanosomes to hyposmotic and hyperosmotic stresses. The same amounts of single marker (WT; blue), TbVtc4 knock-out (cKO; red), and TbVtc4 complemented knock-out (cKO (+Tet); green) BSF trypanosomes were suspended in isotonic buffer. TbVtc4-KO BSF trypanosomes (cKO (−Tet)) were cultured in the absence of tetracycline for 14 days before the experiment. The cells were then treated as described under “Experimental Procedures,” and relative changes in cell volume were followed by monitoring the absorbance at 550 nm. A, changes in cell volume after hyposmotic stress (213 mosM). B, changes in cell volume after hyperosmotic stress (650 mosM). Arrows indicate the time point (3 min) when osmotic stress was induced. A decrease in absorbance corresponds to an increase in cell volume and vice versa. Values are means ± S.D. (error bars) of three different experiments. Asterisks indicate statistically significant differences between cell line patterns, p < 0.05 (Bonferroni’s multiple comparison “a posteriori” test of one-way analysis of variance at all time points after induction of osmotic stress).

FIGURE 7. Effect of inhibition of TbVtc4 expression on virulence in mice. Two experiments involving three groups of five mice that were infected with single marker (WT) and TbVtc4-KO mutant (cKO) BSF trypanosomes (−dox, +dox), were performed. 200 μg/ml doxycycline was supplied in the drinking water of one group of mice for the induction of an ectopic copy of TbVtc4 gene in the cKO cell line (complemented knock-out control). The percentage of mouse survival (A) and parasitemia levels in the blood of infected mice (B) were monitored during 30 days postinfection. The charts combine results from two independent experiments. Error bars, S.D.

the dramatic cell volume stresses of mammalian renal circulation and consequently cannot establish an infection. Alternatively, the increased osmotic sensitivity of TbVtc4-deficient trypanosomes weakens the parasites and makes them unable to evade the host immune response.

Long chain polyP is present in trypanosomes (22), but TbVtc4 is not able to synthesize these polymers; therefore, other enzyme(s) could be involved in this process. We measured the activity of the catalytic region of TbVtc4 because our attempts to recombinantly express the full-length protein in soluble form were unsuccessful. It is possible that the native enzyme can synthesize long chain polyP. However, this is not likely because only short chain polyP synthesis was affected in knock-out parasites.

The palmitoyl proteome of T. brucei has recently been reported (47). Both TbVtc1 and TbVtc4 were reported to be palmitoylated. However, our attempts to demonstrate palmitoylation of TbVtc4 in PCF following established protocols (48, 49) were unsuccessful (data not shown). In summary, the essentiality of TbVtc4 for growth and establishment of an efficient infection suggests that this enzyme is a potential drug target and that it would be possible to develop inhibitors.

Acknowledgments—We thank George A. M. Cross for providing strains 29-13 (PCF) and single marker (BSF) and vectors, Norbert Bakalar for the TbVP1 antibody, Thomas Seebeck for the pMOTag4H vector, and Wandy Beatty for help with the immunogold electron microscopy.
