Abstract

In this paper we develop the theory of quantum reverse hypercontractivity inequalities and show how they can be derived from log-Sobolev inequalities. Next we prove a generalization of the Stroock-Varopoulos inequality in the non-commutative setting which allows us to derive quantum hypercontractivity and reverse hypercontractivity inequalities solely from 2-log-Sobolev and 1-log-Sobolev inequalities respectively. We then prove some tensorization-type results providing us with tools to prove hypercontractivity and reverse hypercontractivity not only for certain quantum superoperators but also for their tensor powers. Finally as an application of these results, we generalize a recent technique for proving strong converse bounds in information theory via reverse hypercontractivity inequalities to the quantum setting. We prove strong converse bounds for the problems of quantum hypothesis testing and classical-quantum channel coding based on the quantum reverse hypercontractivity inequalities that we derive.

1 Introduction

Let \( \{ T_t : t \geq 0 \} \) be a continuous semigroup of stochastic maps (a Markov semigroup) with a unique stationary distribution \( \pi \). Defining the \( p \)-norm, for \( p \geq 1 \), of a function \( f \) by \( \| f \|_p := (\mathbb{E}|f|^p)^{1/p} \), where the expectation is with respect to \( \pi \), a simple convexity-type argument verifies that \( \| T_t f \|_p \leq \| f \|_p \). That is, \( T_t \), for all \( t \geq 0 \), is a contraction under \( p \)-norms. Since \( p \mapsto \| f \|_p \) is non-decreasing, a stronger contractivity inequality is the following:

\[
\| T_t f \|_p \leq \| f \|_q, \tag{1}
\]

for \( 1 \leq q \leq p \) and \( t = t(p) \) a function of \( p \) satisfying \( t(q) = 0 \). Thus an inequality of this form is called a hypercontractivity inequality. Since \( T_0 \) equals the identity map, the inequality (1) for \( p = q \) reduces to an equality. Thus its infinitesimal version around \( t = 0 \) must also hold. This infinitesimal version is derived from the derivative of the left hand side of (1) and is called a q-log-Sobolev inequality\textsuperscript{2}. Such an inequality involves two quantities: the entropy function and the Dirichlet form. A log-Sobolev inequality guarantees the existence of a positive constant, called a log-Sobolev constant, up to which the entropy function is dominated by the Dirichlet form. Not only can one derive log-Sobolev inequalities from hypercontractivity ones, but a collection of the former inequalities can also be used to prove hypercontractivity inequalities through integration. Thus log-Sobolev inequalities and hypercontractivity inequalities are essentially equivalent.

A fundamental tool in the theory of log-Sobolev inequalities is the Stroock-Varopoulos inequality. This inequality enables us to compare the Dirichlet forms associated to different values of \( q \), using which

\textsuperscript{1}Recall that \( \{ T_t : t \geq 0 \} \) forms a semigroup.
\textsuperscript{2}For sake of brevity, we refrain from defining the phrases shown in italics throughout this introduction. Please refer to the main text and references therein for details.
a log-Sobolev inequality for \( q = 2 \) can be used to derive a log-Sobolev inequality for any \( q \). Indeed, the Stroock-Varopoulos inequality allows us to derive a collection of log-Sobolev inequalities from a single one, from which hypercontractivity inequalities can be proven by integration.

Hypercontractivity inequalities were first studied in the context of quantum field theory [18, 33, 40], but later found several important applications in different areas of mathematics, e.g., concentration of measure inequalities [3, 35], transportation cost inequalities [17], estimating the mixing times [14], analysis of Boolean functions [11] and information theory [1, 20]. One of the main ingredients of most of these applications is the so-called tensorization property. It states that the hypercontractivity inequality

\[
\|T_t^\otimes n f\|_p \leq \|f\|_q,
\]

is satisfied for every \( n \geq 1 \) if and only if it holds for \( n = 1 \). That is, the hypercontractivity of \( T_t \) is equivalent to the hypercontractivity of its tensor powers. Proof of the tensorization property is not hard, and can be obtained using the multiplicativity of the operator \((q \to p)\)-norm. Another proof uses subadditivity of the entropy function and the equivalence of log-Sobolev and hypercontractivity inequalities.

Hypercontractivity inequalities can also be studied for \( p, q < 1 \). Although \( \| \cdot \|_p \) for \( p < 1 \) is not a norm, it satisfies the reverse Minkowski inequality from which one can show that \( \|T_t f\|_p \geq \|f\|_p \) when \( p < 1 \). Thus it is natural to consider inequalities of the form (1) for \( p, q < 1 \) in the reverse direction. Such inequalities are called reverse hypercontractivity inequalities. The theory of log-Sobolev inequalities for the range of \( q < 1 \) is developed similarly and can be used for proving reverse hypercontractivity inequalities as well [29].

Quantum hypercontractivity inequalities: The theory of hypercontractivity and log-Sobolev inequalities in the quantum (non-commutative) case has been developed by Olikerwilicz and Zegarlinski [36]. Here the semigroup of stochastic maps is replaced by a semigroup of quantum superoperators representing the time evolution of an open quantum system under the Markovian approximation in the Heisenberg picture. Kastoryano and Temme in [21] used log-Sobolev inequalities to estimate the mixing time of quantum Markov semigroups. The study of quantum reverse hypercontractivity was initiated in [10], where following [29] some applications were discussed. For other applications of hypercontractivity inequalities in quantum information theory see [24, 12, 32]. See also [6] for the theory of hypercontractivity and log-Sobolev inequalities for completely bounded norms.

Due to the non-commutative features of quantum physics, hypercontractivity and log-Sobolev inequalities in the quantum case are much more complicated. Therefore, despite the apparent analogy with the classical (i.e. commutative) case, several complications arise. In particular, one of the main drawbacks of the theory in the non-commutative case is the lack of a general quantum Stroock-Varopoulos inequality. That is, in the quantum case, one cannot derive hypercontractivity inequalities solely from a 2-log-Sobolev one. Weaker versions of the quantum Stroock-Varopoulos inequality, called regularity and strong regularity properties, were considered in the literature and proved for certain examples [36, 21]. The most general result in this direction is a proof of the strong regularity property for a wide class of quantum Markov semigroups obtained in [4].

Even more problematic is the issue of tensorization. As mentioned before, the proof of the tensorization property in the commutative case is quite easy and can be done with at least two methods, yet none of them generalize to the non-commutative case: The superoperator norm is not multiplicative in general, and the subadditivity of entropy employed in the commutative case does not hold in the quantum one. Thus far, the tensorization property has been proven only for a few special examples of quantum Markov semigroups. In particular, it was proven for the qubit depolarizing semigroup in [25, 21] and is generalized for all unital qubit semigroups in [23]. Moreover, in [11] some techniques were developed for bounding the log-Sobolev constants associated to the tensor powers of quantum Markov semigroups, which can be considered as an intermediate resolution of the tensorization problem.

1.1 Our results

In this paper we first develop the theory of quantum reverse hypercontractivity inequalities beyond the unital case. This is done almost in a manner analogous to the (forward) hypercontractivity inequalities. Here, in contrast to [36, 21], we need to use different normalizations for the entropy function as well as

2
the Dirichlet form to make them non-negative even for parameters \( p < 1 \). Our results in this part are summarized in Theorem 11.

Our next result is a quantum Stroock-Varopoulos inequality for both the forward and reverse cases. We prove this inequality under the assumption of strong reversibility of the semigroup. We provide two proofs for the quantum Stroock-Varopoulos inequality. The first proof is based on ideas in [9] and [21]. The second proof is based on ideas in [4] in which the strong regularity is proven under the same assumption. Indeed, our quantum Stroock-Varopoulos inequality is a generalization of the strong regularity property established in [4]. Theorem 13 states our result in this part.

We then prove some tensorization-type results. The first one, Theorem 19, provides a uniform bound on the 1-log-Sobolev constant of generalized depolarizing semigroups and their tensor powers. The proof of this result is a generalization of the proof of a similar result in the classical case in [29]. This tensorization result together with our Stroock-Varopoulos inequality gives a reverse hypercontractivity inequality which is used in the subsequent section. The second tensorization result, Theorem 21, shows that the 2-log-Sobolev constant of the \( n \)-fold tensor power of a qubit generalized depolarizing semigroup is independent of \( n \). Next, in Theorem 25 we explicitly compute this 2-log-Sobolev constant. Finally, in Corollary 26 we use these results to establish a uniform bound on the 2-log-Sobolev constant of any qubit quantum Markov semigroup and its tensor powers. We note that the latter bound improves over the bounds provided in [41].

Let us briefly explain the ideas behind the latter tensorization results. Previously, Theorem 21 was known in the unital case (the usual depolarizing semigroup), the proof of which was based on an inequality on the norms of a \( 2 \times 2 \) block matrix and its submatrices from [22]. Our proof of Theorem 21 is based on the same inequality. First in Lemma 22 we derive an infinitesimal version of that inequality in terms of the entropies of a \( 2 \times 2 \) block matrix and its submatrices, and then use it to prove Theorem 21. To prove Theorem 25 we need to show that a certain function of qubit density matrices is optimized over diagonal ones. Once we show this, the explicit expression for the 2-log-Sobolev constant is obtained from the associated classical log-Sobolev constant derived in [13]. Finally, Corollary 26 is a quantum generalization of a classical result from [14] with an essentially similar proof except that we should take care of tensorization separately.

Finally, we apply the quantum reverse hypercontractivity in proving strong converse bounds for the tasks of quantum hypothesis testing and classical-quantum channel coding. In the next section, we briefly explain the key idea behind the application of reverse hypercontractivity to the problem of classical hypothesis testing.

1.2 Application to hypothesis testing problem

Recently, the authors of [26] introduced a new technique to prove strong converse results in information theory using reverse hypercontractivity inequalities. In the following we briefly explain the ideas via the problem of hypothesis testing.

Suppose that \( n \) samples independently drawn from a probability distribution on some sample space \( \Omega \) are provided, and the task is to distinguish between two possible hypotheses which are given by the distributions \( P \) and \( Q \) on \( \Omega \). In this setting, we apply a test function \( f: \Omega^n \rightarrow \{0,1\} \) to make the decision: Letting \( (x_1,\ldots,x_n) \in \Omega^n \) be the observed samples, if \( f(x_1,\ldots,x_n) \) equals 1, we infer the hypothesis to be \( P \), and otherwise infer it to be \( Q \). The following two types of error may occur: the error of Type I of wrongly inferring the distribution to be \( Q \) given by \( \alpha_n(f) := P^{\otimes n}(f = 0) \), and the error of Type II of wrongly inferring the distribution to be \( P \) given by \( \beta_n(f) := Q^{\otimes n}(f = 1) \). In the asymmetric regime, we further assume that \( \alpha_n(f) \) is uniformly bounded by some fixed error \( \varepsilon \in (0,1) \), and we are interested in the smallest possible achievable error \( \beta_n(f) \).

The idea in [26] is to use the following variational formula for the relative entropy between \( P \) and \( Q \) (see, e.g., [38]):

\[
nD(P||Q) = D(P^{\otimes n}||Q^{\otimes n}) = \sup_{g>0} \mathbb{E}_{P^{\otimes n}}[\log g] - \log \mathbb{E}_{Q^{\otimes n}}[g],
\]

where \( \mathbb{E}_{P^{\otimes n}} \) stands for the expectation with respect to the distribution \( P^{\otimes n} \), and the maximum is over functions \( g \) on \( \Omega^n \). This formula is indeed used for \( g \) being a noisy version of \( f \). To get this noisy version.

\footnote{The test could be probabilistic, but for simplicity of presentation we restrict to deterministic tests.}
a Markov semigroup is employed.

For any function $h : \Omega \to \mathbb{R}$ define
\[
T_t(h) := e^{-t}h + (1 - e^{-t})\mathbb{E}_P[h],
\]
That is, for every $x \in \Omega$, we have $T_t(h)(x) = e^{-t}h(x) + (1 - e^{-t})\mathbb{E}_P[h]$. Then \(\{T_t : t \geq 0\}\) forms a semigroup that satisfies the following reverse hypercontractivity inequality \cite{29}:
\[
\|T_t(h)\|_q \geq \|h\|_p, \quad \forall p, q, t, \quad 0 \leq q < p < 1, \quad t \geq \log \left(\frac{1 - q}{1 - p}\right),
\]
where the norms are defined with respect to the distribution $P$, i.e., $\|h\|_p = (\mathbb{E}_P[|h|^p])^{1/p}$. The idea is to use \cite{2} for $g = T_t^\otimes n f$ as follows:
\[
\text{Bounding the second term on the right hand side is easy. Letting } \gamma = \frac{\|dp\|_\infty}{\|dQ\|_\infty}, \text{ we have}
\]
\[
\mathbb{E}_{Q^n}[T_t^\otimes n(f)] = \mathbb{E}_{Q^n}\left[(e^{-t} + (1 - e^{-t})\mathbb{E}_P)^\otimes n\right]
\leq \mathbb{E}_{Q^n}\left[(e^{-t} + \gamma(1 - e^{-t})\mathbb{E}_Q)^\otimes n\right]
= (e^{-t} + \gamma(1 - e^{-t}))^n \mathbb{E}_{Q^n}[f]
= (e^{-t} + \gamma(1 - e^{-t}))^n \beta_n(f)
\leq e^{(\gamma - 1)nt}\beta_n(f),
\]
where the last inequality follows from $e^{\gamma t} - 1 \geq (e^t - 1)$ for $\gamma \geq 1$.

Now we need to bound the first term in terms of $\alpha_n(f)$. The crucial observation here is that
\[
\|h\|_0 = \lim_{r \to 0} \|h\|_r = e^{\mathbb{E}_P[\log|h|]},
\]
It is then natural to use the reverse hypercontractivity inequality \cite{4} for $q = 0$. In fact, using the tensorization property, that \cite{4} also holds for $T_t^\otimes n$, we have
\[
\mathbb{E}_{P^n}[\log T_t f] = \log \|T_t^\otimes n(f)\|_0
\geq \log \|f\|_1 - e^{-t}
\geq \frac{1}{1 - e^{-t}} \log \mathbb{E}_{P^n}[f]
\geq \left(\frac{1}{t} + 1\right) \log(1 - \alpha_n(f)),
\]
where the second line follows from the reverse hypercontractivity inequality, the third line follows from the fact that $T_t^\otimes n(f)$ takes values in $[0, 1]$, and the last line follows from $e^{-t} \geq 1 - t$. Now using \cite{5} and \cite{8} in \cite{4}, using $\alpha_n(f) \leq \varepsilon$ and optimizing over the choice of $t > 0$ we arrive at
\[
\beta_n(f) \geq (1 - \varepsilon)e^{-nD(P||Q)-2\sqrt{n}\|\mathbb{E}_{P^n}[dp]\|_\infty \log \frac{1}{\varepsilon}}.
\]
In the present work, we show that the above analysis can be carried over to the quantum setting. Let us explain the similarities with the classical case as well as difficulties we face in doing this. Firstly, a variational expression for the quantum relative entropy similar to \cite{2} is already known \cite{37}. Secondly, the semigroup \cite{3} is easily generalized to the generalized depolarizing semigroup in the quantum case. Thirdly, the reverse hypercontractivity inequality \cite{4} is derived in the quantum case from our theory of quantum reverse hypercontractivity as well as our quantum Stroock-Varopoulos inequality. However we need this inequality in its $n$-fold tensor product form, for which we use our tensorization-type result. Also, generalizing the computations in \cite{4} to the quantum case is straightforward. Nevertheless, we face a problem in the next step: The crucial identity \cite{14} no longer holds in the non-commutative case. To get around this problem, instead of a variational formula similar to \cite{2}, we use our quantum reverse hypercontractivity inequality together with a variational formula for $p$-norms (obtained from the reverse Hölder inequality). Then we derive an inequality of the form \cite{15} by taking an appropriate limit.

Section \ref{sec:applications} contains our results on applications of reverse hypercontractivity inequalities to strong converse of the quantum hypothesis testing as well as the classical-quantum channel coding problems.
2 Notations

For a Hilbert space $\mathcal{H}$, the algebra of (bounded) linear operators acting on $\mathcal{H}$ is denoted by $\mathcal{B}(\mathcal{H})$. The adjoint of $X \in \mathcal{B}(\mathcal{H})$ is denoted by $X^\dagger$ and

$$|X| := \sqrt{X^\dagger X}.$$  

The subspace of self-adjoint operators is denoted by $\mathcal{B}_sa(\mathcal{H}) \subset \mathcal{B}(\mathcal{H})$. When $X \in \mathcal{B}_sa(\mathcal{H})$ is positive semi-definite (positive definite) we represent it by $X \geq 0$ ($X > 0$). We let $\mathcal{P}(\mathcal{H})$ be the cone of positive semi-definite operators on $\mathcal{H}$ and $\mathcal{P}_+(\mathcal{H}) \subset \mathcal{P}(\mathcal{H})$ the set of (strictly) positive operators. Further, let $\mathcal{D}(\mathcal{H}) := \{ \rho \in \mathcal{P}(\mathcal{H}) \mid \text{tr} \rho = 1 \}$ denote the set of density operators (or states) on $\mathcal{H}$, and $\mathcal{D}_+(\mathcal{H}) := \mathcal{D}(\mathcal{H}) \cap \mathcal{P}_+(\mathcal{H})$ denote the subset of faithful states. We denote the support of an operator $A$ by $\text{supp}(A)$. We let $I \in \mathcal{B}(\mathcal{H})$ be the identity operator on $\mathcal{H}$, and $I : \mathcal{B}(\mathcal{H}) \rightarrow \mathcal{B}(\mathcal{H})$ be the identity superoperator acting on $\mathcal{B}(\mathcal{H})$.

We sometimes deal with tensor products of Hilbert spaces. In this case, in order to keep track of subsystems, it is appropriate to label the Hilbert spaces as $\mathcal{H}_A, \mathcal{H}_B$ etc. We also denote $\mathcal{H}_A \otimes \mathcal{H}_B$ by $\mathcal{H}_{AB}$. Then the subscript in $X_{AB}$ indicates that it belongs to $\mathcal{B}(\mathcal{H}_{AB})$. We also use $\mathcal{H}^{\otimes n} = \mathcal{H}_{A_1} \otimes \cdots \otimes \mathcal{H}_{A_n}$, where $\mathcal{H}_{A_i}$'s are isomorphic Hilbert spaces. Moreover, for any $S \subseteq \{1, \ldots, n\}$ we use the shorthand notations $A_S := \{ A_j : j \in S \}$, and $\mathcal{H}_{A_S}$ for $\bigotimes_{j \in S} \mathcal{H}_{A_j}$. We also identify $A_{\{1, \ldots, n\}}$ with $A^n$.

A superoperator $\Phi : \mathcal{B}(\mathcal{H}) \rightarrow \mathcal{B}(\mathcal{H})$ is called positive if $\Phi(X) \geq 0$ whenever $X \geq 0$. It is called completely positive if $\mathcal{I} \otimes \Phi$ is positive where $\mathcal{I} : \mathcal{B}(\mathcal{H}') \rightarrow \mathcal{B}(\mathcal{H}')$ is the identity superoperator associated to an arbitrary Hilbert space $\mathcal{H}'$. Observe that a positive superoperator $\Phi$ is Hermitian-preserving meaning that $\Phi(X^\dagger) = \Phi(X)^\dagger$. A superoperator is called unital if $\Phi(I) = I$, and is called trace-preserving if $\text{tr} \Phi(X) = \text{tr} X$ for all $X$. The adjoint of $\Phi$, denoted by $\Phi^*$ is defined with respect to the Hilbert-Schmidt inner product:

$$\text{tr} \left( X^\dagger \Phi(Y) \right) = \text{tr} \left( \Phi^*(X) Y \right).$$  \hspace{1cm} (10)

Note that the adjoint of a unital map is trace-preserving and vice versa.

2.1 Non-commutative weighted $L_p$-spaces

Throughout the paper we fix $\sigma \in \mathcal{D}_+(\mathcal{H})$ to be a positive definite density matrix. We define

$$\Gamma_\sigma(X) := \sigma^{1/2} X \sigma^{1/2}.$$  

Then $\mathcal{B}(\mathcal{H})$ is equipped with the inner product

$$\langle X, Y \rangle_\sigma := \text{tr} \left( X^\dagger \Gamma_\sigma(Y) \right) = \text{tr} \left( \Gamma_\sigma(X^\dagger) Y \right).$$  

Note that if $X, Y \geq 0$ then $\langle X, Y \rangle_\sigma \geq 0$. This inner product induces a norm on $\mathcal{B}(\mathcal{H})$:

$$\|X\|_{2,\sigma} := \sqrt{\langle X, X \rangle_\sigma}.\hspace{1cm} (11)$$

This 2-norm can be generalized for other values of $p$. For every $p \in \mathbb{R} \setminus \{0\}$ we define

$$\|X\|_{p,\sigma} := \text{tr} \left[ \left( \Gamma_\sigma(X) \right)^p \right]^{1/p} = \text{tr} \left[ \left( \sigma^{-1/2} X \sigma^{-1/2} \right)^p \right]^{1/p} = \|\Gamma_\sigma(X)\|_p,\hspace{1cm} (12)$$

where

$$\|X\|_p := \left( \text{tr} |X|^p \right)^{1/p},$$

denotes the (generalized) Schatten norm of order $p$. In particular, if $X > 0$ then $\|X\|_{p,\sigma} = \text{tr} \left[ \Gamma_\sigma(X)^p \right]$. Note that this definition reduces to (11) when $p = 2$. The values of $\|X\|_{p,\sigma}$ for $p \in \{0, \pm \infty\}$ are defined in the limits. Observe that $\|X\|_{p,\sigma} = \|X^\dagger\|_{p,\sigma}$ for all $X$. Moreover, $\|\cdot\|_{p,\sigma}$ for $1 \leq p < \infty$ satisfies the
triangle inequality (the Minkowski inequality) and is a norm. The dual of this norm is $\| \cdot \|_{\hat{p},\sigma}$ where $\hat{p}$ is the Hölder conjugate of $p$ given by

$$\frac{1}{p} + \frac{1}{\hat{p}} = 1.$$  \hspace{1cm} (13)

We indeed for $1 \leq p \leq \infty$ and arbitrary $X$ have [36]

$$\|X\|_{p,\sigma} = \sup_{Y} \frac{|\langle X, Y \rangle_{\sigma}|}{\|Y\|_{\hat{p},\sigma}}. \quad \hspace{1cm} (14)$$

Moreover, for $-\infty \leq p < 1$ and positive definite $X$ we have

$$\|X\|_{p,\sigma} = \inf_{Y > 0} \frac{\langle X, Y \rangle_{\sigma}}{\|Y\|_{\hat{p},\sigma}}. \quad \hspace{1cm} (15)$$

This inequality is a consequence of the reverse Hölder inequality:

**Lemma 1** (Reverse Hölder inequality). Let $X \geq 0$ and $Y > 0$. Then, for any $p < 1$ with Hölder conjugate $\hat{p}$ we have

$$\langle X, Y \rangle_{\sigma} \geq \|X\|_{p,\sigma} \|Y\|_{\hat{p},\sigma}.$$  

Proof. The proof is a direct generalization of equation (32) of [42] (see also Lemma 5 of [10]): for any $A \geq 0$ and $B > 0$,

$$\text{tr}(AB) \geq \|A\|_{p} \|B\|_{\hat{p}}.$$  

From there, choosing $A := \Gamma_{\sigma}^{\frac{1}{p}}(X)$ and $B := \Gamma_{\sigma}^{\frac{1}{\hat{p}}}(Y)$,

$$\langle X, Y \rangle_{\sigma} = \text{tr}(\sigma^{1/p}X^{1/p}\sigma^{1/\hat{p}}Y^{1/\hat{p}}) = \text{tr}(AB) \geq \|A\|_{p} \|B\|_{\hat{p}} = \|X\|_{p,\sigma} \|Y\|_{\hat{p},\sigma}. \hspace{1cm} \Box$$

Another property of $\| \cdot \|_{p,\sigma}$ for $-\infty \leq p < 1$ is the reverse Minkowski inequality. As mentioned above, when $p \geq 1$, the triangle inequality is satisfied due to the Minkowski inequality. When $p < 1$ we have the inequality in the reverse direction:

$$\|X\|_{p,\sigma} + \|Y\|_{p,\sigma} \geq \|X + Y\|_{p,\sigma}.$$  

Again this inequality in the special case of $\sigma$ being the completely mixed state is proven in [10] but the generalization to arbitrary $\sigma$ is immediate.

For arbitrary $p,q$ define the power operator by

$$I_{q,p}(X) := \Gamma_{\sigma}^{\frac{1}{q}} \left( \Gamma_{\sigma}^{\frac{1}{p}}(X) \right)^{\frac{1}{q}}.$$  

Here are some immediate properties of the power operator.

**Proposition 2.** [36, 21]

(i) $\|I_{q,p}(X)\|_{q,\sigma}^{q} = \|X\|_{p,\sigma}^{p}$. In particular we have $\|I_{p,p}(X)\|_{p,\sigma} = \|X\|_{p,\sigma}$.

(ii) $I_{q,r} \circ I_{r,p} = I_{q,p}$.

(iii) For $X \geq 0$ we have $I_{p,p}(X) = X$. 

6
2.2 Entropy

For a given $\sigma \in \mathcal{D}_+(\mathcal{H})$ and arbitrary $p \neq 0$ we define the entropy function\(^4\) for $X > 0$ by

$$\text{Ent}_{p,\sigma}(X) := \text{tr}\left(\left(\Gamma^{\frac{1}{p}}(X)\right)^p \cdot \log \left(\Gamma^{\frac{1}{p}}(X)\right)^p\right) - \text{tr}\left(\left(\Gamma^{\frac{1}{\sigma}}(X)\right)^p \cdot \log \sigma\right) - \|X\|_{p,\sigma}^p \cdot \log \|X\|_{p,\sigma}^p.$$  

As usual, the entropy function for $p \in \{0, \pm \infty\}$ is defined in the limit.

**Remark 1.** When $p > 0$, in the definition of the entropy we can take $X$ to be positive semi-definite. However, when $p < 0$, we need to consider $X$ to be positive definite in order to avoid difficulties. For this reason, in the rest of the paper we state our definitions and results for positive definite $X$, keeping in mind that when $p, q > 0$ they can easily be generalized to positive semi-definite $X$ (say, by taking an appropriate limit).

The significance of the entropy function is its relation to the derivative of the $p$-norm.

**Proposition 3.** \(^{[20],[21]}\) For an arbitrary map $p \mapsto X_p$ we have

$$\frac{d}{dp} \|X_p\|_{p,\sigma} = \frac{1}{p^2} \|X_p\|_{p,\sigma}^{1-p} \left(\frac{1}{2} \text{Ent}_{p,\sigma}(I_{p,p}(X_p)) + \frac{1}{2} \text{Ent}_{p,\sigma}(I_{p,p}(X_p^\dagger)) + \gamma\right).$$

Here $\gamma$ is given by

$$\gamma := \frac{p^2}{2} \left(\text{tr}\left[\Gamma^{\frac{1}{p}}(Z_p) \cdot \Gamma^{\frac{1}{p}}(X_p) \cdot \left|\Gamma^{\frac{1}{p}}(X_p)\right|^{-2}\right] + \text{tr}\left[\Gamma^{\frac{1}{\sigma}}(X_p^\dagger) \cdot \Gamma^{\frac{1}{\sigma}}(Z_p) \cdot \left|\Gamma^{\frac{1}{\sigma}}(X_p)\right|^{-2}\right]\right),$$

where $Z_p := \frac{d}{dp} X_p$.

We will be using two special cases of this proposition. First, if $X_p > 0$ for all $p$, we have

$$\frac{d}{dp} \|X_p\|_{p,\sigma} = \frac{1}{p^2} \|X_p\|_{p,\sigma}^{1-p} \left(\text{Ent}_{p,\sigma}(X_p) + p^2 \text{tr}\left[\Gamma^{\frac{1}{p}}(Z_p) \cdot \Gamma^{\frac{1}{p}}(X_p)^{p-1}\right]\right).$$

Second, if $X_p = X$ is independent of $p$ we have

$$\frac{d}{dp} \|X\|_{p,\sigma} = \frac{1}{p^2} \|X\|_{p,\sigma}^{1-p} \left(\frac{1}{2} \text{Ent}_{p,\sigma}(I_{p,p}(X)) + \frac{1}{2} \text{Ent}_{p,\sigma}(I_{p,p}(X^\dagger))\right). \quad (16)$$

We will also use the following properties of the entropy function that are easy to verify.

**Proposition 4.** \(^{[21]}\)

(i) $\text{Ent}_{p,\sigma}(I_{p,2}(X)) = \text{Ent}_{q,\sigma}(I_{q,2}(X))$ for all $p, q$ and $X$.

(ii) $\text{Ent}_{p,\sigma}(cX) = c^p \text{Ent}_{p,\sigma}(X)$ for all $X > 0$ and constants $c > 0$.

(iii) For any density matrix $\rho$ we have

$$\text{Ent}_{2,\sigma}(\Gamma^{\frac{1}{2}}(\sqrt{\rho})) = D(\rho\|\sigma),$$

where $D(\rho\|\sigma) = \text{tr}(\rho \log \rho) - \text{tr}(\rho \log \sigma)$ is Umegaki’s relative entropy.

(iv) For any density matrix $\rho$ we have

$$\text{Ent}_{1,\sigma}(\Gamma^{-1}(\rho)) = D(\rho\|\sigma).$$

**Corollary 5.**

(a) For all $X > 0$ and arbitrary $p$ we have $\text{Ent}_{p,\sigma}(X) \geq 0$.

---

\(^4\)Our entropy function here is different from the one in \(^{[21]}\) by a factor of $p$. This modification ensures us that if $X$ and $\sigma$ commute, we get the usual entropy function in the classical case. Moreover, this extra factor makes the entropy function non-negative even for $p < 0$. 
(b) For all $X$, the map $p \mapsto \|X\|_{p,\sigma}$ is non-decreasing.

(c) $X \mapsto \text{Ent}_{1,\sigma}(X)$ is a convex function on positive semidefinite matrices.

Proof. (a) By part (i) of the previous proposition it suffices to prove the theorem for $p = 1$. Moreover, by part (ii) we may assume that $X$ is of the form $X = \Gamma^{-1}_\sigma(\rho)$ for some density matrix $\rho$. Then by part (iv) we have $\text{Ent}_{1,\sigma}(X) = D(\rho\|\sigma) \geq 0$.

(b) By (a) both $\text{Ent}_{p,\sigma}(I_{p,p}(X))$ and $\text{Ent}_{p,\sigma}(I_{p,p}(X^*))$ are non-negative. Thus using (16) the derivative of $p \mapsto \|X\|_{p,\sigma}$ is non-negative, and this function is non-decreasing.

(c) Given $X, Y \geq 0$ define $f(p) = \frac{1}{2}(\|X\|_{p,\sigma} + \|Y\|_{p,\sigma}) - \text{Ent}_{1,\sigma}(X + Y)$. Using Proposition 3 we have $f'(1) = \frac{1}{2}(\text{Ent}_{1,\sigma}(X) + \text{Ent}_{1,\sigma}(Y)) - \text{Ent}_{1,\sigma}(1/2(X + Y))$. On the other hand by the Minkowski inequality $f(p) \geq 0$ for all $p \geq 1$. Moreover, $f(1) = 0$. Therefore, $f'(1) \geq 0$ which gives the desired result.

2.3 Quantum Markov semigroups

A quantum Markov semigroup (QMS) is the basic model for the evolution of an open quantum system in the Markovian regime. Such quantum Markov semigroup (in the Heisenberg picture) is a set \{\Phi_t : t \geq 0\} of completely positive unital superoperators $\Phi_t : B(H) \to B(H)$ of the form

$$\Phi_t = e^{-tL},$$

where $L : B(H) \to B(H)$ is a superoperator called the Lindblad generator of the semigroup. The general form of such a Lindblad generator is characterized in [25, 16]. We note that $\Phi_0 = I$ and $\Phi_{t+s} = \Phi_s \circ \Phi_t$.

Moreover, for any $X$ we have

$$\frac{d}{dt}\Phi_t(X) = -L \circ \Phi_t(X) = -\Phi_t \circ L(X).$$

In particular, since $\Phi_t$ is assumed to be unital, we have

$L(I) = 0$.

Throughout the paper we assume that $L$ is primitive, which means that $I$ is the unique (up to scaling) element in the kernel of $L$.

The dual of $L$ generates the associated Markov semigroup in the Schrödinger picture: $\Phi_t^* = e^{-tL^*}$ where $L^*$ is adjoint of $L$ with respect to the Hilbert-Schmidt inner product defined in [10]. We say that the quantum Markov semigroup is $\sigma$-reversible or satisfies the detailed balanced condition with respect to some positive definite density matrix $\sigma$ if

$$\Gamma_\sigma \circ L \circ \Gamma^{-1}_\sigma = L^*.$$

From this equation it is clear that

$L^*(\sigma) = 0,$

and that $\sigma$ is a fixed point of $\Phi_t^*$. Observe that, by the primitivity assumption, $\sigma$ is the unique fixed point of $\Phi_t^*$ up to scaling.

We will frequently use the following immediate consequence of reversibility.

Lemma 6. If $L$ is $\sigma$-reversible if and only if both $L$ and $\Phi_t$ are self-adjoint with respect to the inner product $\langle \cdot, \cdot \rangle_\sigma$, which means that for all $X, Y$ we have

$$\langle X, L(Y) \rangle_\sigma = \langle L(X), Y \rangle_\sigma,$$

$$\langle X, \Phi_t(Y) \rangle_\sigma = \langle \Phi_t(X), Y \rangle_\sigma.$$
A reversible quantum Markov semigroup is called \textit{p-contractive} if it is a contraction under the \(p\)-norm, that is, for all \(t \geq 0\) and \(X > 0\) we have
\[
\|\Phi_t(X)\|_{p,\sigma} \leq \|X\|_{p,\sigma}, \quad \text{if } \quad p \geq 1,
\]
and
\[
\|\Phi_t(X)\|_{p,\sigma} \geq \|X\|_{p,\sigma}, \quad \text{if } \quad p < 1.
\]
We say the semigroup is contractive if it is \(p\)-contractive for all \(p\).

Two remarks are in line. Firstly, as mentioned before, when \(p > 0\) in the above definition we may safely take \(X \geq 0\) (instead of \(X > 0\)). For uniformity of presentation we prefer to take \(X > 0\) in order to jointly consider the cases \(p > 0\) and \(p \leq 0\) in the definitions. Of course in the former case by taking an appropriate limit, a contractivity inequality for \(X \geq 0\) can be derived once we have one for \(X > 0\). Secondly, in the above definition we restrict to positive definite (or positive semidefinite) \(X\) since here \(\Phi_t\) is a completely positive map, and the superoperator norm of completely positive maps (at least for \(p \geq 1\)) is optimized over positive semidefinite operators (see e.g. \cite{10.2307/1969889} and reference therein).

**Proposition 7.** (i) Any \(\sigma\)-reversible quantum Markov semigroup is \(p\)-contractive for \(p \in (-\infty, -1] \cup [1/2, +\infty)\).

(ii) A \(\sigma\)-reversible quantum Markov semigroup with \(\sigma = \mathbb{I}/d\) being the completely mixed state, is \(p\)-contractive for all \(p\).

The reader familiar with the notion of \textit{sandwiched Rényi relative entropy} \cite{2020arXiv200300529M, 2020arXiv200300529M} would notice that \(p\)-contractivity is related to \cite{10.2307/1969889} the data processing inequality of \(\sigma\)-sandwiched \(p\)-Rényi relative entropy, which is known to hold \cite{15, 5, 30} for \(p \in (-\infty, -1] \cup [1/2, 1)\) based on new ideas which may be of independent interest. Moreover, later in Corollary \cite{15} under a stronger assumption than \(\sigma\)-reversibility we will prove \(p\)-contractivity for all \(p\).

An important example of classical semigroups is generated by the map \(f \mapsto f - \mathbb{E}f\), where the expectation is with respect to some fixed distribution. This generator is sometimes called the \textit{simple Lindblad generator} \cite{29}. The quantum analog of simple generators is
\[
\mathcal{L}(X) := X - \text{tr}(\sigma X)\mathbb{I},
\]
for some positive definite density matrix \(\sigma\). Observe that \(\mathcal{L}\) is primitive, and \(\mathcal{L}^*(X) = X - \text{tr}(X)\sigma\) satisfied the detailed balanced condition with respect to \(\sigma\). The quantum Markov semigroup associated to this Lindblad generator is
\[
\Phi_t(X) = e^{-t}X + (1 - e^{-t})\text{tr}(\sigma X)\mathbb{I}. \tag{17}
\]
In the special case where \(\sigma\) is the completely mixed state, \(\Phi_t\) and \(\Phi^*_t\) coincide and become depolarizing channels. Indeed, \cite{17} is a \textit{generalized depolarizing channel} in the Heisenberg picture.

Having two Lindblad generators \(\mathcal{L}\) and \(\mathcal{K}\) associated to two semigroups \(\{\Phi_t : t \geq 0\}\) and \(\{\Psi_t : t \geq 0\}\), respectively, we may consider a new Lindblad generator \(\mathcal{L} \otimes \mathcal{I} + \mathcal{I} \otimes \mathcal{K}\). This Lindblad generator generates the semigroup \(\{\Phi_t \otimes \Psi_t : t \geq 0\}\). Moreover, letting
\[
\tilde{\mathcal{L}}_i := \mathcal{L} \otimes \mathcal{I} \otimes \mathcal{I} \otimes (\mathcal{I} \otimes \mathcal{I})
\]
we have
\[
\tilde{\Phi}^\otimes n_t = e^{-t} \sum_{i=1}^n \tilde{\mathcal{L}}_i.
\]
Note that, if \(\mathcal{L}\) is primitive and reversible with respect to \(\sigma\), then \(\sum_{i=1}^n \tilde{\mathcal{L}}_i\) is also primitive and reversible with respect to \(\sigma^\otimes n\).

### 2.4 Dirichlet form

We now define the \textit{Dirichlet form}\footnote{Again, our definition of the Dirichlet form is different from that of \cite{21} by a factor of \(p/2\).} associated to a \(\sigma\)-reversible Markov semigroup by
\[
\mathcal{E}_{p,\mathcal{L}}(X) = \frac{p}{4} \langle \text{tr}_p(X), \mathcal{L}(X) \rangle_{\sigma},
\]
where \(\hat{p}\) is the Hölder conjugate of \(p\). Verification of the following properties of the Dirichlet form is easy.
The best constant \( \beta \) by \( \alpha \) of Markov semigroups. to the non-commutative case for unital semigroups in [10]. Here we generalize the theory for general gives hypercontractivity ones. The theory of reverse hypercontractivity inequalities have been generalized (log-Sobolev) inequalities. They are essentially equivalent objects, so proving log-Sobolev inequalities

\begin{align*}
\text{Proposition 8.} & \quad (i) \quad \mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)) = \mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)) \text{ for all } p \text{ and } X. \\
(ii) \quad \mathcal{E}_{p,\mathcal{L}}(cX) = c^p\mathcal{E}_{p,\mathcal{L}}(X) \text{ for } X \geq 0 \text{ and constant } c \geq 0. \\
(iii) \quad \mathcal{E}_{2,\mathcal{L}}(X) = \langle X, \mathcal{L}(X) \rangle_{\sigma} \text{ for all } X > 0. \\
(iv) \quad \mathcal{E}_{1,\mathcal{L}}(X) = \frac{1}{4} \text{tr} \left[ \Gamma_{\sigma}(\mathcal{L}(X)) \cdot \left( \log \Gamma_{\sigma}(X) - \log \sigma \right) \right].
\end{align*}

The non-negativity of the Dirichlet form is not clear from its definition. Here we prove the non-negativity assuming that the semigroup is \( p \)-contractive. According to Proposition 8 we then conclude the non-negativity of \( \mathcal{E}_{p,\mathcal{L}}(X) \) for \( p \notin (-1, 1/2) \). Later on, based on a stronger assumption than \( \sigma \)-reversibility, we will prove \( \mathcal{E}_{p,\mathcal{L}}(X) \geq 0 \) for all values of \( p \).

\begin{align*}
\text{Proposition 9. Suppose that } \mathcal{L} \text{ is } \sigma \text{-reversible and generates a } p \text{-contractive semigroup. Then } \mathcal{E}_{p,\mathcal{L}}(X) \geq 0 \text{ for all } X > 0. 
\end{align*}

\begin{proof}
Define
\begin{align*}
g(t) & := \hat{p}\|\Phi_t(X)\|_{p,\sigma}^p - \hat{p}\|X\|_{p,\sigma}^p.
\end{align*}

By assumption, for all \( t \geq 0 \) we have \( g(t) \leq 0 \). We note that \( g(0) = 0 \). Therefore, \( g'(0) \leq 0 \). We compute
\begin{align*}
g'(0) & = \frac{d}{dt} \|\Phi_t(X)\|_{p,\sigma}^p \bigg|_{t=0} \\
& = \frac{d}{dt} \|\Phi_t(X)\|_{p,\sigma} \bigg|_{t=0} \\
& = -p\hat{p} \text{tr} \left[ \Gamma_{\frac{p}{2},\sigma} \circ \Phi_t(X)^p \right] \\
& = -p\hat{p} \text{tr} \left[ \mathcal{L}(X) \cdot \Gamma_{\frac{p}{2},\sigma}(X)^p \right] \\
& = -p\hat{p}(I_{p,\mathcal{L}}(X), \mathcal{L}(X))_{\sigma}.
\end{align*}

This gives \( \mathcal{E}_{p,\mathcal{L}}(X) \geq 0. \)
\end{proof}

2.5 Hypercontractivity and logarithmic-Sobolev inequalities

We showed in Proposition 4 that \( \Phi_t \) belonging to a Markov semigroup is contractive, at least for certain values of \( p \). That is, \( \|\Phi_t(X)\|_{p,\sigma} \) is bounded (from above or below depending on whether \( p \geq 1 \) or \( p < 1 \)) by \( \|X\|_{p,\sigma} \). On the other hand, By part (b) of Corollary 5 bounding \( \|\Phi_t(X)\|_{p,\sigma} \) by \( \|X\|_{q,\sigma} \) when \( 1 \leq q < p < q < 1 \) is a stronger inequality than contractivity. Such inequalities are called hypercontractivity inequalities or reverse hypercontractivity inequalities depending on whether \( 1 \leq q < p \) or \( p < q < 1 \) respectively. These inequalities have found a wide range applications in the literature.

It is well-known that quantum hypercontractivity inequalities stem from quantum logarithmic-Sobolev (log-Sobolev) inequalities. They are essentially equivalent objects, so proving log-Sobolev inequalities gives hypercontractivity ones. The theory of reverse hypercontractivity inequalities have been generalized to the non-commutative case for unital semigroups in [10]. Here we generalize the theory for general Markov semigroups.

Given a primitive Lindblad generator \( \mathcal{L} \) that is reversible with respect to a positive definite density matrix \( \sigma \), a \( p \)-log-Sobolev inequality is an inequality of the form
\[ \beta \text{Ent}_{p,\sigma}(X) \leq \mathcal{E}_{p,\mathcal{L}}(X), \quad \forall X > 0. \]

The best constant \( \beta \) satisfying the above inequality is called the \( p \)-log-Sobolev constant and is denoted by \( \alpha_p(\mathcal{L}) \). That is,
\[ \alpha_p(\mathcal{L}) := \inf \frac{\mathcal{E}_{p,\mathcal{L}}(X)}{\text{Ent}_{p,\sigma}(X)}, \]

where the infimum is taken over \( X > 0 \) with \( \text{Ent}_{p,\sigma}(X) \neq 0 \).

By the following proposition we can restrict ourselves to log-Sobolev constants for values of \( p \in [0, 2] \).

Proposition 10. \( \alpha_p(\mathcal{L}) = \alpha_p(\mathcal{L}) \) for all Lindblad generators \( \mathcal{L} \).
Proof. Identifying $X$ with $I_{p,2}(Y)$, for some arbitrary $Y > 0$, this is an immediate consequence of part (i) of Proposition 3 and part (i) of Proposition 8.

We can now state how log-Sobolev inequalities are related to hypercontractivity and reverse hypercontractivity inequalities. As mentioned above the first part of the following theorem is already known [20] [21].

**Theorem 11.** Let $\mathcal{L}$ be a primitive Lindblad generator that is reversible with respect to positive definite density matrix $\sigma$. Then the following holds:

- (Hypercontractivity) Suppose that $\beta_2 = \inf_{p \in [1,2]} \alpha_p(\mathcal{L}) > 0$. Then for $1 \leq q \leq p$ and
  \[ t \geq \frac{1}{4\beta_2} \log \frac{p-1}{q-1}, \quad (19) \]
  we have $\|\Phi_t(X)\|_{p,\sigma} \leq \|X\|_{q,\sigma}$ for all $X > 0$.

- (Reverse hypercontractivity) Suppose that $\beta_1 = \inf_{p \in [0,1]} \alpha_p(\mathcal{L}) > 0$. Then for $p \leq q < 1$ and
  \[ t \geq \frac{1}{4\beta_1} \log \frac{p-1}{q-1}, \quad (20) \]
  we have $\|\Phi_t(X)\|_{p,\sigma} \geq \|X\|_{q,\sigma}$ for all $X > 0$.

The proof strategy of this theorem is quite standard. Here we present a proof for the sake of completeness.

Proof. It suffices to prove the theorem when $t = \frac{1}{p} \log \frac{p-1}{q-1}$ for $\beta$ being either $\beta_2$ or $\beta_1$ depending on whether we prove the hypercontractivity part or the reverse hypercontractivity part. Thus, fix $q$ and define

\[ t(p) := \frac{1}{4\beta} \log \frac{p-1}{q-1}. \]

Define

\[ f(p) := \|\Phi_t(X_p)\|_{p,\sigma} - \|X\|_{q,\sigma} = \|X_p\|_{p,\sigma} - \|X\|_{q,\sigma}, \]

where $X_p := \Phi_t(X) > 0$. To continue the proof we compute the derivative of $f(p)$ using Proposition 3

\[ f'(p) = \frac{d}{dp} \|X_p\|_{p,\sigma} = \frac{1}{p^2} \|X_p\|_{p,\sigma}^{1-p} \cdot \left( \text{Ent}_{p,\sigma}(X_p) + p^2 \text{tr} \left[ \frac{1}{\sigma} (X_p) \cdot X_p \right] \right), \]

where

\[ Z_p = \frac{d}{dp} X_p = -t'(p) \mathcal{L} (X_p) = -\frac{1}{4\beta(p-1)} \mathcal{L} (X_p). \]

Therefore,

\[ f'(p) = \frac{1}{p^2} \|X_p\|_{p,\sigma}^{1-p} \cdot \left( \text{Ent}_{p,\sigma}(X_p) - \frac{1}{\beta} \mathcal{E}_{p,\mathcal{L}} (X_p) \right). \]

Now suppose that $q \geq 1$ and $\beta \leq \alpha_p(\mathcal{L})$ for all $p \in [1,2]$. Then for $p \geq q$ we have

\[ \text{Ent}_{p,\sigma}(X_p) \leq \frac{1}{\alpha_p(\mathcal{L})} \mathcal{E}_{p,\mathcal{L}} (X_p) \leq \frac{1}{\beta} \mathcal{E}_{p,\mathcal{L}} (X_p). \]

As a result, $f'(p) \leq 0$ for all $p \geq q$. Since $f(q) = 0$ we conclude that $f(p) \leq 0$ for all $p \geq q$. This gives the hypercontractivity part of the theorem.

For the reverse hypercontractivity part, assume that $q < 1$ and $\beta \leq \alpha_p(\mathcal{L})$ for all $p \in [0,1]$. Then for $p \leq q$ we have

\[ \text{Ent}_{p,\sigma}(X_p) \leq \frac{1}{\alpha_p(\mathcal{L})} \mathcal{E}_{p,\mathcal{L}} (X_p) \leq \frac{1}{\beta} \mathcal{E}_{p,\mathcal{L}} (X_p), \]

where the second inequality holds since $p < 1$, so either $p$ or its Hölder conjugate belongs to $[0,1]$. Therefore, $f'(p) \leq 0$ for all $p \leq q < 1$, and since $f(q) = 0$, $f(p) \geq 0$ for all $p < q$. 

\[ \square \]
3 Quantum Stroock-Varopoulos inequality

In the previous section we developed the basic tools required to understand quantum hypercontractivity and reverse hypercontractivity inequalities and log-Sobolev inequalities. By Theorem [11] to obtain hypercontractivity and reverse hypercontractivity inequalities we need to find bounds on log-Sobolev constants in ranges $p \in [1, 2]$ or $p \in [0, 1]$. Now the question is how such bounds can be found.

In the classical (commutative) case, the most relevant $p$-log-Sobolev constants are $\alpha_2(L)$ and $\alpha_1(L)$. Indeed, $p \mapsto \alpha_p(L)$ is a non-increasing function on $p \in [0, 2]$, so in Theorem [11] the parameters $\beta_1$ and $\beta_2$ can be replaced with $\alpha_1(L)$ and $\alpha_2(L)$ respectively. This result is proven via comparison of the Dirichlet forms, an inequalities that is sometimes called the Stroock-Varopoulos inequality.

In this section we prove a quantum generalization of the Stroock-Varopoulos inequality, and conclude that in Theorem [11] we can take $\beta_p = \alpha_p(L)$ for $p = 1, 2$. We should point out that a quantum Stroock-Varopoulos inequality in the special case of $\sigma$ being the completely mixed state is proven in [10]. Also, a weaker version of the Stroock-Varopoulos inequality (called strong $L_p$-regularity) for certain Lindblad generators is proven in [21]. A strong $L_p$-regularity is also proven in [4] which we generalize to a quantum Stroock-Varopoulos inequality.

The assumption of $\sigma$-reversibility is not enough for us for proving the quantum Stroock-Varopoulos inequality. We indeed need $L$ to be self-adjoint with respect to an inner product different from $\langle \cdot, \cdot \rangle_{\sigma}$ defined above (see Lemma [5]). In the following we first define this new inner product, state some of its properties and then go to our quantum Stroock-Varopoulos inequality.

3.1 A new inner product

Define the inner product $\langle \cdot, \cdot \rangle_{1, \sigma}$ on $B(H)$ by

$$\langle X, Y \rangle_{1, \sigma} := \text{tr}(\sigma X^\dagger Y).$$

We note that this inner product coincides with $\langle X, Y \rangle_{\sigma} = \text{tr}(\sigma^{1/2} X^\dagger \sigma^{1/2} Y)$ when, e.g., $X$ and $\sigma$ commute. But in general $\langle \cdot, \cdot \rangle_{1, \sigma}$ is different from $\langle \cdot, \cdot \rangle_{\sigma}$.

The following lemma is first proven in [9]. We will give a prove here for the sake of completeness.

Lemma 12. Let $L$ be a Lindblad generator that is self-adjoint with respect to the inner product $\langle \cdot, \cdot \rangle_{1, \sigma}$ defined above. Then the followings hold.

(i) $L$ commutes with the superoperator $\Delta_\sigma(X) := \sigma X \sigma^{-1}$.

(ii) $L$ is self-adjoint with respect to the inner product $\langle \cdot, \cdot \rangle_{\sigma}$.

Based on part (ii) of this lemma (see also Lemma [3]) we say that a Lindblad generator $L$ is strongly $\sigma$-reversible if it is self-adjoint with respect to the inner product $\langle \cdot, \cdot \rangle_{1, \sigma}$.

Proof. (i) Using the fact the $L(Y)^\dagger = L(Y^\dagger)$, for all $X, Y$ we have

$$\langle X, \Delta_\sigma \circ L(Y) \rangle_{1, \sigma} = \text{tr}(\sigma X^\dagger \sigma L(Y) \sigma^{-1})$$

$$= \text{tr}(X^\dagger \sigma L(Y))$$

$$= \langle L(Y)^\dagger, X^\dagger \rangle_{1, \sigma}$$

$$= \langle L(Y^\dagger), X^\dagger \rangle_{1, \sigma}$$

$$= \langle X^\dagger, L(X^\dagger) \rangle_{1, \sigma}$$

$$= \text{tr}(\sigma Y L(X)^\dagger)$$

$$= \text{tr}(\Delta_\sigma(Y) \sigma L(X)^\dagger)$$

$$= \langle L(X), \Delta_\sigma(Y) \rangle_{1, \sigma}$$

$$= \langle X, L \circ \Delta_\sigma(Y) \rangle_{1, \sigma}.$$

This gives $\Delta_\sigma \circ L = L \circ \Delta_\sigma$. 

12
(ii) Follows easily from (i) and the fact that
\[
\langle X, Y \rangle_\sigma = \langle Y^\dagger, \Delta^1_\sigma(X^\dagger) \rangle_1, \sigma.
\]

The following lemma is indeed a consequence of Theorem 3.1 of [9]. Here we prefer to present a direct proof.

**Lemma 13.** Let \( \mathcal{L} \) be a strongly \( \sigma \)-reversible Lindblad generator. Then for every \( t \geq 0 \) there are operators \( R_k \in \mathcal{B}(\mathcal{H}) \) and \( \omega_k \geq 0 \) such that \( \sigma R_k = \omega_k R_k \sigma \),
\[
\Phi_t(X) = \sum_k R_k X R_k^\dagger,
\]
and \( \sum_k R_k R_k^\dagger = \mathbb{I} \).

**Proof.** By Lemma 12 the Lindblad generator \( \mathcal{L} \) and then \( \Phi_t = e^{-t \mathcal{L}} \) commute with \( \Delta_\sigma \), i.e.,
\[
\Phi_t \circ \Delta_\sigma = \Delta_\sigma \circ \Phi_t.
\]

Fix an orthonormal basis \( \{|i\rangle\}_{i=1}^d \) for the underlying Hilbert space \( \mathcal{H} = \mathcal{H}_A \) and define \( |\Upsilon\rangle := \sum_{i=1}^d |i\rangle_A |i\rangle_B \in \mathcal{H}_{AB} \), where \( \mathcal{H}_B \) is isomorphic to \( \mathcal{H}_A \). It is not hard to verify that for any matrix \( M \) we have
\[
M_A \otimes I_B |\Upsilon\rangle = |\Upsilon\rangle \otimes M^T_B |\Upsilon\rangle,
\]
where the transpose is with respect to the basis \( \{|i\rangle\}_{i=1}^d \).

The Choi-Jamiołkowski representation of \( \Phi_t \) is
\[
J_{AB} := \Phi_t \otimes I_B (|\Upsilon\rangle \langle \Upsilon|).
\]

Then using (24) it is not hard to verify that (23) translates to
\[
\sigma_A^{-1} \otimes \sigma_B^T J_{AB} = J_{AB} \sigma_A^{-1} \otimes \sigma_B^T.
\]

That is, \( J_{AB} \) and \( \sigma_A^{-1} \otimes \sigma_B^T \) commute. On the other hand, \( J_{AB} \) is positive semidefinite since it is the Choi-Jamiołkowski representation of a completely positive map. Therefore, \( J_{AB} \) and \( \sigma_A^{-1} \otimes \sigma_B^T \) can be simultaneously diagonalized in an orthonormal basis, i.e., there exist an orthonormal basis \( \{|v_k\rangle_{AB}\} \) such that
\[
J_{AB} |v_k\rangle = \lambda_k |v_k\rangle,
\]
\[
\sigma_A^{-1} \otimes \sigma_B^T |v_k\rangle = \omega_k^{-1} |v_k\rangle,
\]
where \( \lambda_k, \omega_k \geq 0 \). Define the operator \( V_k \) by
\[
V_k \otimes I_B |\Upsilon\rangle_{AB} = |v_k\rangle_{AB}.
\]

Then again using (24), equation (26) translates to
\[
\sigma^{-1} V_k \sigma = \omega_k^{-1} V_k.
\]

Moreover, equation (25) means that
\[
\Phi_t \otimes I_B (|\Upsilon\rangle \langle \Upsilon|) = J_{AB} = \sum_k \lambda_k |v_k\rangle \langle v_k| = \sum_k \lambda_k (V_k \otimes I_B) |\Upsilon\rangle \langle \Upsilon| (V_k^\dagger \otimes I_B),
\]
which gives
\[
\Phi_t(X) := \sum_k \lambda_k V_k X V_k^\dagger.
\]

Then letting \( R_k := \sqrt{\lambda_k} V_k \) we have \( \sigma R_k = \omega_k R_k \sigma \) and (22) holds. The other equation comes from \( \Phi_t(\mathbb{I}) = \mathbb{I} \). \( \square \)
3.2 Comparison of the Dirichlet forms

We can now state the main result of this section.

**Theorem 14** (Quantum Stroock-Varopoulos inequality). Let \( \mathcal{L} \) be a strongly \( \sigma \)-reversible Lindblad generator, which means that it is self-adjoint with respect to the inner product \( \langle \cdot , \cdot \rangle_\sigma \) defined in (21). Then for all \( X > 0 \) we have

\[
\mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)) \geq \mathcal{E}_{q,\mathcal{L}}(I_{q,2}(X)), \quad 0 \leq p \leq q \leq 2.
\]

We have two proofs for this theorem. The first one, that we present here, is based on ideas in [36, 21]. The second one, that is moved to Appendix B, is based on ideas in [4]. We present both the proofs in this paper since they are different in nature and whose ideas can be useful elsewhere.

**First proof of Theorem 14.** For any \( t \geq 0 \) define the function \( h_t \) by

\[
h_t(s) := \langle I_{2(2-s)/2}(X), \Phi_t \circ I_{2/s,2}(X) \rangle_\sigma.
\]

Since by part (ii) of Lemma 12, \( \Phi_t = e^{-t\mathcal{L}} \) is self-adjoint with respect to the inner product \( \langle \cdot , \cdot \rangle_\sigma \), we have \( h_t(2-s) = h_t(s) \) and \( h_t \) is symmetric about \( s = 1 \). Therefore, all the odd-order derivatives of \( h_t \) at \( t = 1 \) vanish, and we have

\[
h_t(s) = h_t(1) + \sum_{j=1}^{\infty} \frac{c_j}{(2j)!} (s-1)^{2j},
\]

where

\[
c_j = \frac{d^{2j}}{ds^{2j}} h_t(s) \bigg|_{s=1}.
\]

We claim that all the even-order derivatives of \( h_t \) at \( t = 1 \) are non-negative, i.e., \( c_j \geq 0 \). We use Lemma 13 to verify this. Let \( R_k \)'s be matrices such that

\[
\sigma R_k \sigma^{-1} = \omega_k R_k,
\]

with \( \omega_k \geq 0 \) and (22) holds. Then letting \( Y := \Gamma_{\sigma}^{1/2}(X) \) and using (28) we compute

\[
h_t(s) = \text{tr} \left[ \Gamma_{\sigma}^{-\frac{2}{s}}(Y^{2-s}) \cdot \Phi_t(\Gamma_{\sigma}^{-\frac{2}{s}}(Y^s)) \right] = \sum_{k} \text{tr} \left[ Y^{2-s} \sigma^{-\frac{2}{s}} R_k \sigma^{-\frac{2}{s}} Y^s \sigma^{-\frac{2}{s}} R_k \sigma \right] = \sum_{k} \omega_k \text{tr} \left[ Y^{2-s} R_k Y^s R_k \right].
\]

Now diagonalizing \( Y \) in its eigenbasis: \( Y = \sum_{\ell} \mu_{\ell} |\ell \rangle \langle \ell| \), we find that

\[
h_t(s) = \sum_{k,\ell,\ell'} |\langle \ell| R_k |\ell'\rangle|^2 \left( \frac{\sqrt{\omega_k} \mu_{\ell}}{\mu_{\ell'}} \right)^s.
\]

Therefore, \( h_t(s) \) is a sum of exponential functions with positive coefficients. From this expression it is clear that \( c_j \)'s are all non-negative.

Let us define

\[
g_t(s) := \frac{h_t(s) - h_t(0)}{(s-1)^2 - 1} = \sum_{j=1}^{\infty} \frac{c_j}{(2j)!} \left( \sum_{i=0}^{j-1} (s-1)^{2i} \right).
\]
From this expression it is clear that \( g_t(s) \) is non-decreasing on \([1, +\infty)\). Therefore, \( \lim_{t \to 0^+} \frac{g_t(s)}{t} \) is non-decreasing on \([1, +\infty)\). On the other hand, we have \( h_t(0) = \text{tr}(Y^2) = h_0(s) \). We thus can compute

\[
\lim_{t \to 0^+} \frac{g_t(s)}{t} = \frac{1}{(s - 1)^2 - 1} \lim_{t \to 0^+} \frac{h_t(s) - h_t(0)}{t} = \frac{1}{(s - 1)^2 - 1} \left. \frac{\partial}{\partial t} h_t(s) \right|_{t=0} = -\frac{1}{(s - 1)^2 - 1} \langle I_{2/(2-s),2}(X), \mathcal{L} \circ I_{2/s,2}(X) \rangle_{\sigma}.
\]

Therefore

\[
s \mapsto -\frac{1}{(s - 1)^2 - 1} \langle I_{2/(2-s),2}(X), \mathcal{L} \circ I_{2/s,2}(X) \rangle_{\sigma},
\]

is non-decreasing on \([1, +\infty)\). Now the desired result follows once we identify \( 2/s \) with \( \hat{p} \), its Hölder conjugate).

Here are some important consequences of the above theorem.

**Corollary 15.** Let \( \mathcal{L} \) be a strongly \( \sigma \)-reversible Lindblad generator. Then the followings hold:

(i) For all \( p \in \mathbb{R} \) and \( X > 0 \) we have

\[
\mathcal{E}_{p,\mathcal{L}}(X) \geq 0.
\]

(ii) The associated quantum Markov semigroup is \( p \)-contractive for all \( p \).

As mentioned before, \( p \)-contractivity of \( \Phi_t \) implies that Sandwiched \( p \)-Rényi relative entropy is monotone under \( \Phi_t \). Therefore, when \( \Phi_t \) comes from a Markov semigroup satisfying the above strong reversibility condition, \( p \)-Rényi relative entropy is monotone under \( \Phi_t \) not only for \( p \geq 1/2 \) but all values of \( p \).

**Proof.** (i) By Theorem 14 (and part (i) of Lemma 8) for every \( p \) we have

\[
\mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)) \geq \mathcal{E}_{2,\mathcal{L}}(X).
\]

On the other hand, by Proposition 9 and Proposition 7, we have \( \mathcal{E}_{2,\mathcal{L}}(X) \geq 0 \). Therefore, \( \mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)) \geq 0 \).

(ii) Define \( g(t) \) as in the proof of Proposition 8. By part (i) we have \( g'(t) \leq 0 \) for all \( t \geq 0 \) and \( g(0) = 0 \). Therefore, \( g(t) \geq 0 \) for all \( t \geq 0 \). This gives \( p \)-contractivity. \( \square \)

The following corollary is an immediate consequence of the quantum Stroock-Varopoulos inequality as well as part (i) of Proposition 9.

**Corollary 16.** Let \( \mathcal{L} \) be a strongly \( \sigma \)-reversible Lindblad generator. Then \( p \mapsto \alpha_p(\mathcal{L}) \) is non-increasing on \([0, 2]\)

Now we can state an improvement over Theorem 11.

**Corollary 17.** Let \( \mathcal{L} \) be a strongly \( \sigma \)-reversible Lindblad generator. Then the following holds:

- (Hypercontractivity) For \( 1 \leq q \leq p \) and

\[
t \geq \frac{1}{4 \alpha_2(\mathcal{L})} \log \frac{p - 1}{q - 1},
\]

we have \( \|\Phi_t(X)\|_{p,\sigma} \leq \|X\|_{q,\sigma} \) for all \( X \geq 0 \).
• (Reverse hypercontractivity) For \( p \leq q < 1 \) and
\[
t \geq \frac{1}{4\alpha(L)} \log \frac{p-1}{q-1},
\] (30)
we have \( \|\Phi_t(X)\|_{p,\sigma} \geq \|X\|_{q,\sigma} \) for all \( X > 0 \).

Before ending this section, we state a result that will play an important role in Section 5.

**Lemma 18.** Let \( \{\Phi_t : t \geq 0\} \) be a a primitive quantum Markov semigroup that is strongly \( \sigma \)-reversible. Let \( X, Y > 0 \) and \( -\infty \leq q, p \leq 1 \). Then, for any \( t \geq 0 \) such that \( (1-p)(1-q) \geq e^{-4\alpha(L)t} \) we have
\[
\langle X, \Phi_t(Y) \rangle_\sigma \geq \|X\|_{p,\sigma}\|Y\|_{q,\sigma}
\]

**Proof.** The result follows by a direct application of Lemma 1 together with the reverse hypercontractivity inequality in Corollary 17. \( \square \)

## 4 Tensorization

Our goal in this section is to prove hypercontractivity (or reverse hypercontractivity) inequalities of the form \( \|\Phi_t^\otimes n(X)\|_{p,\sigma^\otimes n} \leq \|X\|_{p,\sigma^\otimes n} \) (or \( \|\Phi_t^\otimes n(X)\|_{p,\sigma^\otimes n} \geq \|X\|_{p,\sigma^\otimes n} \)) for certain ranges of \( t, p, q \) that are independent of \( n \). Indeed, so far we have a theory of using log-Sobolev inequalities to prove such inequalities when \( n = 1 \), but in some applications, e.g., those we present later in this paper, we need such inequalities for arbitrary \( n \). We need some notations to state the problem more precisely.

For a Lindblad generator \( L \) we define
\[
\hat{L}_i := T^{\otimes (i-1)} \otimes L \otimes T^{\otimes (n-i)},
\] (31)
as an operator acting on \( B(H^{\otimes n}) \). We also let
\[
K_n := \sum_{i=1}^{n} \hat{L}_i.
\] (32)
Observe that if \( L \) is (strongly) \( \sigma \)-reversible, then \( K_n \) is (strongly) reversible with respect to \( \sigma^\otimes n \). Moreover, \( \hat{L}_i \)'s commute with each other and
\[
e^{-tK_n} = \Phi_t^\otimes n.
\]
That is, \( K_n \) is a (strongly) \( \sigma^\otimes n \)-reversible Lindblad generator which generates the quantum Markov semigroup \( \{\Phi_t^\otimes n : t \geq 0\} \). Now we can ask how the (reverse) hypercontractivity inequalities associated to \( \Phi_t \) are related to those for \( \Phi_t^\otimes n \). Equivalently, what is the relation between the log-Sobolev constants \( \alpha_p(L) \) to \( \alpha_p(K_n) \) in the commutative (classical) case the answer is easy; \( \alpha_p(K_n) \) equals \( \alpha_p(L) \) for all \( n \), and having a (reverse) hypercontractivity inequality for \( \Phi_t \) immediately gives one for \( \Phi_t^\otimes n \). This is because in the classical case operator norms are multiplicative, or because the entropy function satisfies a certain subadditivity property (see e.g., [29]). The aforementioned property that, in the classical case, \( \alpha_p(K_n) \) is independent of \( n \), is usually called the tensorization property.

Tensorization property of log-Sobolev constants of quantum Lindblad generators, unlike its classical counterpart, is highly non-trivial. Thus proving (reverse) hypercontractivity inequalities that are independent of \( n \) is a hard problem in the non-commutative case. There are some attempts in this direction. Montanaro and Osborne in [28] proved such hypercontractivity inequalities for the qubit depolarizing channel (see also [21]). King [23] generalized this result for all unital qubit Markov semigroups. Cubit et al. developed the theory of quantum reverse hypercontractivity inequalities in the unital case in [10] and proved some tensorization-type results. Also, Cubit et al. [11] developed some techniques for proving bounds on log-Sobolev constants \( \alpha_p(K_n) \) that are independent of \( n \). Beigi and King [6] took the path of developing the theory of log-Sobolev inequalities not for the superoperator norm, but for the completely bounded norm. The point is that completely bounded norms are automatically multiplicative [13], so there is no problem of tensorization for the associated log-Sobolev constants.

In this section we prove two tensorization-type results, one for 1-log-Sobolev constants which will be used for reverse hypercontractivity inequalities, and the other for 2-log-Sobolev constants which would be useful for hypercontractivity inequalities.
Theorem 19. Let \( \sigma_1, \ldots, \sigma_n \) be arbitrary positive definite density matrices. Let \( \mathcal{L}_i(X) = X - \text{tr}(\sigma_i X) I \) be the simple generator associated to the state \( \sigma_i \). Let

\[
\hat{\mathcal{L}}_i := \mathcal{I}^{\otimes(i-1)} \otimes \mathcal{L}_i \otimes \mathcal{I}^{\otimes(n-i)},
\]

and define \( \mathcal{K}_n \) by \( \mathcal{G} \). Then we have \( K_1(\mathcal{K}_n) \geq \frac{1}{e} \).

Letting \( \sigma_i \)'s to be equal in the above theorem, we obtain the promised tensorization-type result for the 1-log-Sobolev constant.\(^6\)

Proof. We need to show that for all \( X_{A^n} \in \mathcal{P}_+(\mathcal{H}_{A^n}) \) we have

\[
\frac{1}{4} \text{Ent}_{1,\sigma_{A^n}}(X_{A^n}) \leq \mathcal{E}_{1,\mathcal{K}_n}(X_{A^n}),
\]

where \( \sigma_{A_i} = \sigma_i \) and

\[
\sigma_{A^n} = \sigma_1 \otimes \cdots \otimes \sigma_n.
\]

Using parts (ii) of Proposition \(^4\) and Proposition \(^8\) without loss of generality we can assume that \( X_{A^n} = \Gamma_{\sigma_{A^n}}(\rho_{A^n}) \) where \( \rho_{A^n} \in \mathcal{D}_+(\mathcal{H}_{A^n}) \) is a density matrix. Then, using parts (iv) of Proposition \(^4\) and Proposition \(^8\) we need to show that

\[
D(\rho_{A^n} \| \sigma_{A^n}) \leq \sum_{i=1}^n \text{tr} \left[ \Gamma_{\sigma_{A^n}} \circ \hat{\mathcal{L}}_i \circ \Gamma_{\sigma_{A^n}}^{-1}(\rho_{A^n}) \cdot \left( \log \rho_{A^n} - \log(\sigma_{A^n}) \right) \right].
\]

Observe that

\[
\Gamma_{\sigma_{A^n}} \circ \hat{\mathcal{L}}_i \circ \Gamma_{\sigma_{A^n}}^{-1} = \mathcal{I}^{\otimes(i-1)} \otimes \left( \Gamma_{\sigma_i} \circ \mathcal{L}_i \circ \Gamma_{\sigma_i}^{-1} \right) \otimes \mathcal{I}^{\otimes(n-i)} = \mathcal{I}^{\otimes(i-1)} \otimes \mathcal{L}_i^* \otimes \mathcal{I}^{\otimes(n-i)},
\]

with \( \mathcal{L}_i^*(Y) = Y - \text{tr}(Y) \sigma_i \). Therefore,

\[
\Gamma_{\sigma_{A^n}} \circ \hat{\mathcal{L}}_i \circ \Gamma_{\sigma_{A^n}}^{-1}(\rho_{A^n}) = \rho_{A^n} - \rho_{A^{-i}} \otimes \sigma_{A_i},
\]

where \( A^{-i} = (A_1, \ldots, A_{i-1}, A_{i+1}, \ldots, A_n) \) and \( \rho_{A^{-i}} = \text{tr}_{A_i}(\rho_{A^n}) \) is the partial trace of \( \rho_{A^n} \) with respect to the \( i \)-th subsystem. Therefore, \( (33) \) is equivalent to

\[
D(\rho_{A^n} \| \sigma_{A^n}) \leq \sum_{i=1}^n \text{tr} \left[ (\rho_{A^n} - \rho_{A^{-i}} \otimes \sigma_{A_i}) \cdot \left( \log \rho_{A^n} - \log(\sigma_{A^n}) \right) \right]
\]

\[
= \sum_{i=1}^n \left[ D(\rho_{A^n} \| \sigma_{A^n}) + D(\rho_{A^{-i}} \otimes \sigma_{A_i}, \rho_{A^n}) - D(\rho_{A^{-i}} \otimes \sigma_{A_i}, \sigma_{A^n}) \right].
\]

Now since \( D(\rho_{A^{-i}} \otimes \sigma_{A_i}, \rho_{A^n}) \geq 0 \), it suffices to show that

\[
D(\rho_{A^n} \| \sigma_{A^n}) \leq \sum_{i=1}^n \left[ D(\rho_{A^n} \| \sigma_{A^n}) - D(\rho_{A^{-i}} \otimes \sigma_{A_i}, \sigma_{A^n}) \right].
\]

We note that \( D(\xi_B \| \tau_B) = -H(B|\xi) - \text{tr}(\xi \log \tau) \) where \( H(B|\xi) = -\text{tr}(\xi \log \xi) \) is the von Neumann entropy. Moreover, \( \log(\xi \otimes \tau) = \log(\xi \otimes I + I \otimes \log \tau) \). Therefore, \( (34) \) is equivalent to

\[
-H(A^n)_{\rho} - \sum_{i=1}^n \text{tr}(\rho_{A_i} \log \sigma_i) \leq \sum_{i=1}^n \left[ -H(A_i^n)_{\rho} - \sum_{j=1}^n \text{tr}(\rho_{A_j} \log \sigma_i) + H(A^{-i})_{\rho} + \sum_{j \neq i} \text{tr}(\rho_{A_j} \log \sigma_i) \right]
\]

\[
= \sum_{i=1}^n \left[ -H(A_i^n)_{\rho} - \text{tr}(\rho_{A_i} \log \sigma_i) + H(A^{-i})_{\rho} \right]
\]

\[
= \sum_{i=1}^n \left[ -H(A_i | A^{-i})_{\rho} - \text{tr}(\rho_{A_i} \log \sigma_i) \right].
\]

\(^6\)After finishing this work we came to know that this theorem in the special case when \( \sigma \) is the completely mixed state was already proved in \( [31] \).
This is itself equivalent to
\[ H(A^n) \rho \geq \sum_{i=1}^{n} H(A_i) \rho, \]
which is an immediate consequence of the data processing inequality (i.e., \( H(B|C) \xi \geq H(B|CD) \xi \)) once we use the chain rule
\[ H(A^n) \rho = \sum_{i=1}^{n} H(A_i|A_1, \ldots, A_{i-1}) \rho. \]

We are done. \( \square \)

We can now use Corollary 17 and the fact that the simple generator is strongly reversible to conclude the following.

**Corollary 20.** Let \( \sigma_1, \ldots, \sigma_n \) be an arbitrary positive definite density matrices. Let \( L_i(X) = X - \text{tr}(\sigma_i X)I \) be the simple generator associated to the generalized depolarizing channel \( \Phi_{t,i}(X) = e^{-t}X + (1 - e^{-t})\text{tr}(\sigma_i X)I \). Define \( \sigma^{(n)}(X) = \sigma_1 \otimes \cdots \otimes \sigma_n \) and \( \Phi_t^{(n)} = \Phi_t \otimes \cdots \otimes \Phi_t \). Then for \( p \leq q < 1 \) and \( t \geq \log \frac{p-1}{q-1} \) we have
\[ \| \Phi_t^{(n)}(X) \|_{p,\sigma^{(n)}} \geq \| X \|_{q,\sigma^{(n)}}, \quad \forall n \geq 1, \]
where \( X \in P_+(\mathcal{H}^\otimes n) \) is arbitrary.

We now state the second tensorization result which is about the 2-log-Sobolev constant.

**Theorem 21.** Let \( \dim \mathcal{H} = 2 \) and \( L(X) = X - \text{tr}(\sigma X)I \) for some positive definite density matrix \( \sigma \in D_+(\mathcal{H}) \). Then we have
\[ \alpha_2(K_n) = \alpha_2(L), \quad \forall n, \]
where \( K_n \) is defined in (32).

Our main tool to prove this theorem is the following entropic inequality that is interesting on its own and can be useful elsewhere.

**Lemma 22.** Let \( \mathcal{H} \) and \( \mathcal{H}' \) be Hilbert spaces with \( \dim \mathcal{H} = 2 \). Let \( X \in P(\mathcal{H} \otimes \mathcal{H}') \) be a positive semidefinite matrix with the block form
\[ X = \begin{pmatrix} A & C \\ C^\dagger & B \end{pmatrix}, \quad (35) \]
where \( A, B, C \in B(\mathcal{H}'). \) For a density matrix \( \rho \in D_+(\mathcal{H}') \), the matrix \( M \) defined as
\[ M = \begin{pmatrix} \|A\|_{2,\rho} & \|C\|_{2,\rho} \\ \|C^\dagger\|_{2,\rho} & \|B\|_{2,\rho} \end{pmatrix} \]
(36)
is positive semidefinite. Moreover, let \( \sigma \in D_+(\mathcal{H}) \) be a density matrix of the form
\[ \sigma = \begin{pmatrix} \theta & 0 \\ 0 & 1 - \theta \end{pmatrix}, \quad (37) \]
where \( \theta \in (0,1) \). Then we have
\[ \text{Ent}_{2,\sigma \otimes \rho}(X) \leq \text{Ent}_{2,\sigma}(M) + \theta \text{Ent}_{2,\rho}(A) + (1 - \theta)\text{Ent}_{2,\rho}(B) + \sqrt{\theta(1 - \theta)} \text{Ent}_{2,\rho}(I_{2,2}(C)) + \sqrt{\theta(1 - \theta)} \text{Ent}_{2,\rho}(I_{2,2}(C^\dagger)). \quad (38) \]
Proof. For any \( p \geq 2 \) define

\[
M_p := \left( \frac{\|A\|_{p,\rho}}{\|C\|_{p,\rho}}, \frac{\|C\|_{p,\rho}}{\|B\|_{p,\rho}} \right),
\]

so that \( M_2 = M \). Since \( X \geq 0 \), both \( A \) and \( B \) are positive semidefinite. Moreover, we have

\[
\Gamma_{\rho\otimes\rho}^\frac{1}{2}(X) = \begin{pmatrix} \Gamma_{\rho}^\frac{1}{2}(A) & \Gamma_{\rho}^\frac{1}{2}(C) \\ \Gamma_{\rho}^\frac{1}{2}(C^\dagger) & \Gamma_{\rho}^\frac{1}{2}(B) \end{pmatrix} \geq 0.
\]

As a result, according to Theorem IX.5.9 of [7] there exists a contraction \( R \in B(\mathcal{H'}) \) such that \( \Gamma_{\rho}^\frac{1}{2}(C) = (\Gamma_{\rho}^\frac{1}{2}(A))^\frac{1}{2} R (\Gamma_{\rho}^\frac{1}{2}(B))^\frac{1}{2} \). Therefore, by Hölder’s inequality we have

\[
\|\Gamma_{\rho}^\frac{1}{2}(C)\|_p = \|(\Gamma_{\rho}^\frac{1}{2}(A))^\frac{1}{2} R (\Gamma_{\rho}^\frac{1}{2}(B))^\frac{1}{2}\|_p \\
\leq \|(\Gamma_{\rho}^\frac{1}{2}(A))^\frac{1}{2}\|_{2p} \cdot \|R\|_\infty \cdot \|(\Gamma_{\rho}^\frac{1}{2}(B))^\frac{1}{2}\|_{2p} \\
\leq \|(\Gamma_{\rho}^\frac{1}{2}(A))^\frac{1}{2}\|_{2p} \cdot \|(\Gamma_{\rho}^\frac{1}{2}(B))^\frac{1}{2}\|_{2p} \\
= \|\Gamma_{\rho}^\frac{1}{2}(A)\|_{2p} \cdot \|\Gamma_{\rho}^\frac{1}{2}(B)\|_{2p}.
\]

Then using \( \|Y\|_{p,\rho} = \|\Gamma_{\rho}^\frac{1}{p}(Y)\|_p \), we find that

\[
\|C\|_{p,\rho} \leq \|A\|_{p,\rho} \cdot \|B\|_{p,\rho},
\]

and hence \( M_p \geq 0 \). In particular, \( M_2 = M \geq 0 \) and \( \text{Ent}_{2,\rho}(M) \) makes sense.

Define \( \psi(p) := \|M_p\|_{p,\rho} - \|X\|_{p,\rho,\otimes,\rho} \). It is shown by King [22] that \( \psi(p) \geq 0 \) for all \( p \geq 2 \). Indeed, this inequality is proven in [22] in the special case where \( \sigma \) and \( \rho \) are the identity operators on the relevant spaces. Nevertheless, we have

\[
\|X\|_{p,\rho,\sigma,\rho} = \left\| \begin{pmatrix} \theta \frac{1}{2} \Gamma_{\rho}^\frac{1}{2}(A) & \theta(1-\theta) \frac{1}{2} \Gamma_{\rho}^\frac{1}{2}(C) \\ (\theta(1-\theta)) \frac{1}{2} \Gamma_{\rho}^\frac{1}{2}(C^\dagger) & (1-\theta) \frac{1}{2} \Gamma_{\rho}^\frac{1}{2}(B) \end{pmatrix} \right\|_p,
\]

and

\[
\|M_p\|_{p,\rho,\sigma,\rho} = \left\| \begin{pmatrix} \theta \frac{1}{2} \|\Gamma_{\rho}^\frac{1}{2}(A)\|_p & \theta(1-\theta) \frac{1}{2} \|\Gamma_{\rho}^\frac{1}{2}(C)\|_p \\ (\theta(1-\theta)) \frac{1}{2} \|\Gamma_{\rho}^\frac{1}{2}(C^\dagger)\|_p & (1-\theta) \frac{1}{2} \|\Gamma_{\rho}^\frac{1}{2}(B)\|_p \end{pmatrix} \right\|_p.
\]

Thus, King’s result holds for arbitrary \( \rho \) and diagonal \( \sigma \) as well, and we have \( \psi(p) \geq 0 \) for all \( p \geq 2 \). On the other hand, a straightforward computation verifies that \( \psi(2) = 0 \). This means that \( \psi'(2) \geq 0 \), i.e.,

\[
\frac{d}{dp} \left( \|M_p\|_{p,\rho,\sigma,\rho} - \|X\|_{p,\rho,\sigma,\rho} \right) \bigg|_{p=2} \geq 0.
\]

The derivatives can be computed using Proposition 3. We have

\[
\frac{d}{dp} \|X\|_{p,\rho,\sigma,\rho} \bigg|_{p=2} = \frac{1}{4} \|X\|_{2,\rho,\sigma,\rho}^{-1} \cdot \text{Ent}_{2,\sigma,\rho}(X),
\]

and

\[
\frac{d}{dp} \|M_p\|_{p,\sigma,\rho} \bigg|_{p=2} = \frac{1}{4} \|M\|_{2,\sigma,\rho}^{-1} \cdot \left( \text{Ent}_{2,\rho}(M) + 4 \text{tr} \left[ \Gamma_{\rho}^\frac{1}{2}(M_2^\dagger) \cdot \Gamma_{\rho}^\frac{1}{2}(M) \right] \right),
\]

where \( M_2 = \frac{d}{dp} M_p \bigg|_{p=2} = \frac{1}{4} \left( \|A\|_{2,\rho,\sigma,\rho}^{-1} \cdot \text{Ent}_{2,\rho}(A) - \|B\|_{2,\rho,\sigma,\rho}^{-1} \cdot \text{Ent}_{2,\rho}(B) \right) \).
and \( w = \left| C \right|_{I_{2,2}}^{-1} \cdot \left( \frac{1}{7} \text{Ent}_{\rho}(I_{2,2}(C)) + \frac{1}{3} \text{Ent}_{\rho}(I_{2,2}(C^t)) \right) \). We conclude that
\[
\frac{d}{dp} \left| M \right|_{\rho,\sigma} \bigg|_{p=2} = \frac{1}{4} \left| M \right|_{I_{2,2}}^{-1} \cdot \left( \text{Ent}_{\rho}(M) + \theta \text{Ent}_{\rho}(A) + (1 - \theta) \text{Ent}_{\rho}(B) \right)
+ \sqrt{\theta(1 - \theta) \text{Ent}_{\rho}(I_{2,2}(C)) + \sqrt{\theta}(1 - \theta) \text{Ent}_{\rho}(I_{2,2}(C^t))}.
\]
Comparing to (39) and using Lemma 23. Also let \( K \) denote the identity superoperators acting on \( \mathcal{B}(\mathcal{H}) \).

We need yet another lemma to prove Theorem 21.

**Lemma 23.** For any Lindblad generator \( K \) that is \( \rho \)-reversible for some positive definite density matrix \( \rho \) we have
\[
\mathcal{E}_{2,K}(I_{2,2}(C)) + \mathcal{E}_{2,K}(I_{2,2}(C^t)) \leq \langle C, K(C) \rangle_{\rho} + \langle C^t, K(C^t) \rangle_{\rho},
\]
for any \( C \).

**Proof.** Define \( D := \Gamma_{\rho}^{-1/2} \). Then for \( j \in \{0, 1\} \)
\[
Y_j := \begin{pmatrix} \left| D \right| & (-1)^j D^t \\ (-1)^j D & \left| D \right| \end{pmatrix} \geq 0,
\]
is positive semidefinite [7]. Since \( \Gamma_{\rho}^{-1/2} \) is completely positive we have
\[
Z_j := \mathcal{I} \otimes \Gamma_{\rho}^{-1/2}(Y_j) = \begin{pmatrix} I_{2,2}(C) & (-1)^j C^t \\ (-1)^j C & I_{2,2}(C^t) \end{pmatrix} \geq 0.
\]
On the other hand, \( \Psi_t = e^{-tK} \) is completely positive. Therefore,
\[
\mathcal{I} \otimes \Psi_t(Z_0) = \begin{pmatrix} \Psi_t(I_{2,2}(C)) & \Psi_t(C^t) \\ \Psi_t(C) & \Psi_t(I_{2,2}(C^t)) \end{pmatrix} \geq 0,
\]
is positive semidefinite. Putting these together we find that
\[
g(t) := \langle Z_1, \mathcal{I} \otimes \Psi_t(Z_0) \rangle_{\mathcal{I} \otimes \rho} \geq 0, \quad \forall t \geq 0.
\]
We note that
\[
g(t) = \langle I_{2,2}(C), \Psi_t(I_{2,2}(C)) \rangle_{\rho} + \langle I_{2,2}(C^t), \Psi_t(I_{2,2}(C^t)) \rangle_{\rho} - \langle C, \Psi_t(C) \rangle_{\rho} - \langle C^t, \Psi_t(C^t) \rangle_{\rho}.
\]
From this expression it is clear that
\[
g(0) = \left\| I_{2,2}(C) \right\|_{2,\rho}^2 + \left\| I_{2,2}(C^t) \right\|_{2,\rho}^2 - \left\| C \right\|_{2,\rho}^2 - \left\| C^t \right\|_{2,\rho}^2 = 0.
\]
Therefore, we must have \( g'(0) \geq 0 \) which is equivalent to the desired inequality.

Now we have all the required tools for proving Theorem 21. Indeed, we can prove a stronger statement out of which Theorem 21 is implied by a simple induction.

**Theorem 24.** Let \( \dim \mathcal{H} = 2 \) and \( \mathcal{L}(X) = X - \text{tr}(\sigma X)I \) for some positive definite density matrix \( \sigma \in \mathcal{D}_+(\mathcal{H}) \). Also let \( K \) be a Lindblad generator associated to a primitive semigroup that is reversible with respect to some positive finite state \( \rho \in \mathcal{D}_+(\mathcal{H}') \). Then we have
\[
\alpha_2(\mathcal{L} \otimes \mathcal{I}' + \mathcal{I} \otimes K) = \min \{ \alpha_2(\mathcal{L}), \alpha_2(K) \},
\]
where \( \mathcal{I} \) and \( \mathcal{I}' \) denote the identity superoperators acting on \( \mathcal{B}(\mathcal{H}) \) and \( \mathcal{B}(\mathcal{H}') \) respectively.
Proof. Let $\alpha = \min\{\alpha_2(\mathcal{L}), \alpha_2(\mathcal{K})\}$. By restricting $X$ in the 2-log-Sobolev inequality to be of the tensor product form and using
\[
\text{Ent}_{2,\sigma \otimes \rho}(Y \otimes Y') = \text{Ent}_{2,\sigma}(Y) + \text{Ent}_{2,\rho}(Y'),
\]
we conclude that $\alpha_2(\mathcal{L} \otimes \mathcal{I} + \mathcal{I} \otimes \mathcal{K}) \leq \alpha$. To prove the inequality in the other direction we need to show that for any $X \in \mathcal{P}(\mathcal{H} \otimes \mathcal{H}')$ we have
\[
\alpha \text{Ent}_{2,\sigma \otimes \rho}(X) \leq \mathcal{E}_{2,\mathcal{L} \otimes \mathcal{I} + \mathcal{I} \otimes \mathcal{K}}(X).
\]
Assume, without loss of generality, that $\sigma$ is diagonal of the form \((37)\), and that $X \in \mathcal{P}(\mathcal{H} \otimes \mathcal{H}')$ has the block form \((39)\). Define $M$ by \((39)\). Then by Lemma \((22)\) we have
\[
\text{Ent}_{2,\sigma \otimes \rho}(X) \leq \text{Ent}_{2,\rho}(M) + \theta \text{Ent}_{2,\rho}(A) + (1 - \theta) \text{Ent}_{2,\rho}(B) + \sqrt{\theta(1 - \theta)} \text{Ent}_{2,\rho}(I_{2,2}(C)) + \sqrt{\theta(1 - \theta)} \text{Ent}_{2,\rho}(I_{2,2}(C^\dagger)).
\]
On the other hand by the definition of $\alpha$ we have
\[
\alpha \text{Ent}_{2,\sigma}(M) \leq \mathcal{E}_{2,\mathcal{L}}(M),
\]
and
\[
\alpha \text{Ent}_{2,\rho}(Y) \leq \mathcal{E}_{2,\mathcal{K}}(Y),
\]
for all $Y \in \{A, B, I_{2,2}(C), I_{2,2}(C^\dagger)\}$. Therefore, we have
\[
\alpha \text{Ent}_{2,\sigma \otimes \rho}(X) \leq \mathcal{E}_{2,\mathcal{L}}(M) + \theta \mathcal{E}_{2,\mathcal{K}}(A) + (1 - \theta) \mathcal{E}_{2,\mathcal{K}}(B)
\]
\[
+ \sqrt{\theta(1 - \theta)} \mathcal{E}_{2,\mathcal{K}}(I_{2,2}(C)) + \sqrt{\theta(1 - \theta)} \mathcal{E}_{2,\mathcal{K}}(I_{2,2}(C^\dagger))
\]
\[
\leq \mathcal{E}_{2,\mathcal{L}}(M) + \theta \mathcal{E}_{2,\mathcal{K}}(A) + (1 - \theta) \mathcal{E}_{2,\mathcal{K}}(B)
\]
\[
+ \sqrt{\theta(1 - \theta)} \mathcal{E}_{2,\mathcal{K}}(C, \mathcal{K}) + \sqrt{\theta(1 - \theta)} \mathcal{E}_{2,\mathcal{K}}(C^\dagger, \mathcal{K}).
\]
where in the second inequality we use Lemma \((23)\). We now have
\[
\mathcal{E}_{2,\mathcal{L} \otimes \mathcal{I} + \mathcal{I} \otimes \mathcal{K}}(X) = \langle X, (\mathcal{L} \otimes \mathcal{I} + \mathcal{I} \otimes \mathcal{K}) \rangle_{\sigma \otimes \rho}
\]
\[
= \langle X, \mathcal{L} \otimes \mathcal{I}'(X) \rangle_{\sigma \otimes \rho} + \left( \begin{array}{cc}
A & C \\
C^\dagger & B
\end{array} \right)^{\sigma \otimes \rho}.
\]
We compute each term in the above sum separately.
\[
\langle X, \mathcal{L} \otimes \mathcal{I}'(X) \rangle_{\sigma \otimes \rho}
\]
\[
= \theta(1 - \theta)\langle A - B, C \rangle + \theta(1 - \theta)\langle B, A - B \rangle + 2\sqrt{\theta(1 - \theta)}\langle C, C \rangle
\]
\[
\geq \theta(1 - \theta)\|A\|_{2,\rho}^2 + \theta(1 - \theta)\|B\|_{2,\rho}^2 - 2\theta(1 - \theta)\|A\|_{2,\rho} \cdot \|B\|_{2,\rho} + 2\sqrt{\theta(1 - \theta)}\|C\|_{2,\rho}
\]
\[
= \langle M, \mathcal{L}(M) \rangle_{\sigma}
\]
\[
= \mathcal{E}_{2,\mathcal{L}}(M).\]
For the second term we compute
\[
\left( \begin{array}{cc}
A & C \\
C^\dagger & B
\end{array} \right)^{\sigma \otimes \rho}
\]
\[
= \theta\langle A, \mathcal{K}(A) \rangle_{\rho} + (1 - \theta)\langle B, \mathcal{K}(B) \rangle_{\rho}
\]
\[
+ \sqrt{\theta(1 - \theta)}\langle C, \mathcal{K}(C) \rangle_{\rho} + \sqrt{\theta(1 - \theta)}\langle C^\dagger, \mathcal{K}(C^\dagger) \rangle_{\rho}
\]
\[
= \theta \mathcal{E}_{2,\mathcal{K}}(A) + (1 - \theta) \mathcal{E}_{2,\mathcal{K}}(B)
\]
\[
+ \sqrt{\theta(1 - \theta)}\mathcal{E}_{2,\mathcal{K}}(C, \mathcal{K}) + \sqrt{\theta(1 - \theta)}\mathcal{E}_{2,\mathcal{K}}(C^\dagger, \mathcal{K}).
\]
Therefore, we have
\[
\mathcal{E}_{2,\mathcal{L}}(X) \geq \mathcal{E}_{2,\mathcal{L}}(M) + \theta \mathcal{E}_{2,\mathcal{K}}(A) + (1 - \theta)\mathcal{E}_{2,\mathcal{K}}(B) + \sqrt{\theta(1 - \theta)}\|C, \mathcal{K}(C)\| + \sqrt{\theta(1 - \theta)}\|C', \mathcal{K}(C')\|.
\]
Comparing this to (41) we arrive at the desired inequality (40).

We now give the exact expression of the 2-log-Sobolev constant of the simple Lindblad generator (in any dimension).

**Theorem 25.** Let \( \sigma \in \mathcal{D}_1(\mathcal{H}) \) be arbitrary and let \( \mathcal{L}(X) = X - \text{tr}(\sigma X)I \) be the simple Lindblad generator. Then we have
\[
\alpha_2(\mathcal{L}) = \frac{1 - 2s_{\min}(\sigma)}{\log(1/s_{\min}(\sigma) - 1)},
\]
where \( s_{\min}(\sigma) \) is the minimum eigenvalue of \( \sigma \).

**Proof.** Since both \( \text{Ent}_{2,\sigma}(X) \) and \( \mathcal{E}_{2,\mathcal{L}}(X) \) are homogenous of degree two, to prove a log-Sobolev inequality, without loss of generality we can assume that \( X \) is of the form \( X = \Gamma_{\sigma}^{-1/2}(\sqrt{\sigma}) \) where \( \rho \) is a density matrix. In this case
\[
\text{Ent}_{2,\sigma}(X) = D(\rho||\sigma), \quad \langle X, \mathcal{L}X \rangle_{\sigma} = 1 - \left[ \text{tr}(\sqrt{\sigma} \sqrt{\rho}) \right]^2.
\]
Let \( \sigma = \sum_{i=1}^d s_i |i\rangle \langle i| \) and \( \rho = \sum_{k=1}^d r_k |\bar{k}\rangle \langle \bar{k}| \) be the eigen-decompositions of \( \sigma \) and \( \rho \). Then
\[
\text{Ent}_{2,\sigma}(X) = \sum_{k=1}^d r_k \log r_k - \sum_{i,k=1}^d |\langle i|\bar{k}\rangle|^2 r_k \log s_i,
\]
and
\[
\langle X, \mathcal{L}X \rangle_{\sigma} = 1 - \left( \sum_{i,k=1}^d |\langle i|\bar{k}\rangle|^2 \sqrt{s_i r_k} \right)^2.
\]
Let \( A = (a_{ik})_{d \times d} \) be a \( d \times d \) matrix whose entries are given by
\[
a_{ik} = |\langle i|\bar{k}\rangle|^2.
\]
Observe that, fixing the eigenvalues \( s_i \)'s and \( r_k \)'s, the entropy \( \text{Ent}_{2,\sigma}(X) \) is a linear function of \( A \) and \( \mathcal{E}_{2,\mathcal{L}}(X) \) is concave function of \( A \). On the other hand, since both \( \{|1\}, \ldots, |d\| \rangle \) and \( \{|\bar{1}\}, \ldots, |\bar{d}\| \rangle \) form orthonormal bases, \( A \) is a doubly stochastic matrix. Then by Birkhoff’s theorem, \( A \) can be written as a convex combination of permutations matrices. We conclude that if an inequality of the form
\[
\beta \left( \sum_{k=1}^d r_k \log r_k - \sum_{i,k=1}^d a_{ik} r_k \log s_i \right) \leq 1 - \left( \sum_{i,k=1}^d a_{ik} \sqrt{s_i r_k} \right)^2,
\]
holds for all permutation matrices \( A \), then it holds for all doubly stochastic \( A \), and then for all \( \sigma, \rho \) with the given eigenvalues. We note that \( A \) is a permutation matrix when \( \{|1\}, \ldots, |d\| \rangle \) and \( \{|\bar{1}\}, \ldots, |\bar{d}\| \rangle \) are the same bases (under some permutation) which means that \( \sigma \) and \( \rho \) commute. Therefore, a log-Sobolev inequality of the form
\[
\beta \text{Ent}_{2,\sigma}(\Gamma_{\sigma}^{-1/2}(\rho)) \leq \mathcal{E}_{2,\mathcal{L}}(\Gamma_{\sigma}^{-1/2}(\rho)),
\]
holds for all \( \rho \) if and only if it holds for all \( \rho \) that commute with \( \sigma \). That is, to find the log-Sobolev constant
\[
\alpha_2(\mathcal{L}) = \inf_{\rho} \frac{\mathcal{E}_{2,\mathcal{L}}(\Gamma_{\sigma}^{-1/2}(\rho))}{\text{Ent}_{2,\sigma}(\Gamma_{\sigma}^{-1/2}(\rho))},
\]
we may restrict to those \( \rho \) that commute with \( \sigma \). This optimization problem over such \( \rho \) is equivalent to computing the 2-log-Sobolev constant of the classical simple Lindblad generator, and has been solved in Theorem A.1 of [43].
We can now derive a tensorization-type result for a wide class of Lindblad generators. Let $\mathcal{L}$ be a $\sigma$-reversible and primitive Lindblad generator. Recall that the spectral gap of $\mathcal{L}$ is defined by

$$\lambda(\mathcal{L}) = \inf_{X} \frac{\mathcal{E}_2,\mathcal{L}(X)}{\text{Var}_{\sigma}(X)},$$

where $\text{Var}_{\sigma}(X) = \langle X, X \rangle_{\sigma} - \langle X, 1 \rangle_{\sigma}^2 = \|X\|_{\sigma}^2 - \langle X, 1 \rangle_{\sigma}^2$, see e.g. [21]. Observe that $\text{Var}_{\sigma}(X)$ is the squared length of the projection of $X$ onto the subspace orthogonal to $\mathcal{1} \in \mathcal{B}(\mathcal{H})$ with respect to the inner product $\langle \cdot, \cdot \rangle_{\sigma}$. On the other hand, $I$ is the sole $0$-eigenvector of $\mathcal{L}$ which is self-adjoint with respect to this inner product. Therefore, $\lambda(\mathcal{L})$ is the minimum non-zero eigenvalue of $\mathcal{L}$. Note that by Proposition 7 and Proposition 9 the Dirichlet form $\mathcal{E}_2,\mathcal{L}$ is non-negative, so $\lambda(\mathcal{L}) > 0$. Indeed, $\lambda(\mathcal{L})$ is really the spectral gap of $\mathcal{L}$ above the zero eigenvalue.

The spectral gap satisfies tensorization property. Observe that

$$\mathcal{K}_n = \sum_{i=1}^{n} \hat{\mathcal{L}}_i,$$

is a sum of mutually commuting operators. Then the eigenvalues of $\mathcal{K}_n$ are summations of eigenvalues of individual $\hat{\mathcal{L}}_i$’s. Since each $\hat{\mathcal{L}}_i$ is a tensor product of $\hat{\mathcal{L}}_i$’s, the set of its eigenvalues is the same as that of $\mathcal{L}$. Using these we conclude that

$$\lambda(\mathcal{K}_n) = \lambda(\mathcal{L}), \quad \forall n. \quad (43)$$

It is well-known that $\lambda(\mathcal{L}) \geq 2\alpha_2(\mathcal{L})$. The following corollary gives a lower bound on $\alpha_2(\mathcal{L})$ in terms of $\lambda(\mathcal{L})$.

**Corollary 26.** Let $\dim \mathcal{H} = 2$ and $\sigma \in \mathcal{D}_+(\mathcal{H})$. For any $\sigma$-reversible primitive Lindblad generator $\mathcal{L}$ we have

$$\alpha_2(\mathcal{K}_n) \geq \frac{1 - 2s_{\min}(\sigma)}{\log(1/s_{\min}(\sigma) - 1)} \lambda(\mathcal{L}).$$

This corollary is a non-commutative version of Corollary A.4 of [11] and gives a stronger bound comparing to Corollary 6 of [11]. It would be interesting to compare this corollary with the result of King [23] who generalized the hypercontractivity inequalities of [28] for the unital qubit depolarizing channel to all unital qubit quantum Markov semigroups. Here, having a bound on the 2-log-Sobolev constant of the $\sigma$-reversible generalized qubit depolarizing channel (and its tensorization property), we derive a bound on the 2-log-Sobolev constant of all qubit $\sigma$-reversible semigroups.

**Proof.** Let $\mathcal{L}'$ be the simple Lindblad generator that is $\sigma$-reversible, and let $X \in \mathcal{P}(\mathcal{H}^{\otimes n})$ be arbitrary. Then by Theorem [21] and Theorem 25 we have

$$\frac{1 - 2s_{\min}(\sigma)}{\log(1/s_{\min}(\sigma) - 1)} \text{Ent}_{2,\sigma^\otimes n} \leq \sum_{i=1}^{n} \langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n}. \quad (44)$$

Let $\mathcal{W}_i \subset \mathcal{B}(\mathcal{H}^{\otimes n})$ be the subspace spanned by operators of the form $A_1 \otimes \cdots \otimes A_n \in \mathcal{B}(\mathcal{H}^{\otimes n})$ with $A_i = 1 \in \mathcal{B}(\mathcal{H})$. In other words, $\mathcal{W}_i = \ker(\hat{\mathcal{L}}_i)$. Then $\langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n}$ equals the squared length of the projection of $X$ onto $\mathcal{W}_i^\perp$. On the other hand, since $\mathcal{L}$ is primitive and $\sigma$-reversible, we also have $\mathcal{W}_i = \ker \hat{\mathcal{L}}_i$ and $\mathcal{W}_i^\perp$ is invariant under $\hat{\mathcal{L}}_i$. Moreover, by definition $\lambda(\hat{\mathcal{L}}_i)$ is the minimum eigenvalue of $\hat{\mathcal{L}}_i$ restricted to $\mathcal{W}_i^\perp$ (i.e., the minimum non-zero eigenvalue). We conclude that

$$\lambda(\hat{\mathcal{L}}_i) \langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n} \leq \langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n}.$$

On the other hand since $\hat{\mathcal{L}}_i$ equals the tensor product of $\mathcal{L}$ with some identity superoperators, $\lambda(\hat{\mathcal{L}}_i) = \lambda(\mathcal{L})$. Therefore,

$$\lambda(\mathcal{L}) \langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n} \leq \langle X, \hat{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n}.$$

---

7This 0-eigenvector is unique since $\mathcal{L}$ is assumed to be primitive.
Using this in (44) we arrive at
\[
    \lambda(\mathcal{L}) \frac{1 - 2s_{\min}(\sigma)}{\log \left(1/s_{\min}(\sigma) - 1\right)} \text{Ent}_{2,\sigma^\otimes n} \leq \sum_{i=1}^{n} \langle X, \tilde{\mathcal{L}}_i(X) \rangle_{\sigma^\otimes n} = \langle X, \mathcal{K}_n(X) \rangle_{\sigma^\otimes n}.
\]
This gives the desired bound on \( \alpha_2(\mathcal{K}_n) \).

**Corollary 27.** Let \( \dim \mathcal{H} = 2 \) and \( \sigma \in \mathcal{D}_1(\mathcal{H}) \). Let \( \mathcal{L} \) be a \( \sigma \)-reversible primitive Lindblad generator. Then for any \( 1 \leq q \leq p \) and \( t \geq 0 \) satisfying
\[
    t \geq \frac{\log \left(1/s_{\min}(\sigma) - 1\right)}{4\lambda(\mathcal{L}) (1 - 2s_{\min}(\sigma))} \log \frac{p - 1}{q - 1},
\]
we have \( \|\Phi^{\otimes n}_\mathcal{L}(X)\|_{p,\sigma} \leq \|X\|_{q,\sigma} \) for all \( X > 0 \).

# 5 Application: optimal second-order converses

One of the primary goals of information theory is to find optimal rates of information-theoretic tasks. For instance, for the task of information transmission over a noisy channel, this optimal rate is the capacity. The latter is said to satisfy the strong converse property if any attempt to transmit information at a rate higher than it fails with certainty in the limit of infinitely many uses of the channel. In this section, we show how reverse hypercontractivity inequalities can be used to derive finite sample size strong converse bounds in the tasks of asymmetric quantum hypothesis testing and classical communication through a classical-quantum channel.

## 5.1 Quantum hypothesis testing

Binary quantum hypothesis testing concerns the problem of discriminating between two different quantum states, and is essential for various quantum information-processing protocols. Suppose that a party, Bob, receives a quantum system, with the knowledge that it is prepared either in the state \( \rho \) (the null hypothesis) or in the state \( \sigma \) (the alternative hypothesis) over a finite-dimensional Hilbert space \( \mathcal{H} \). His aim is to infer which hypothesis is true, i.e., which state the system is in. To do so he performs a measurement on the system that he receives. This is most generally described by a POVM \( \{T, \mathbb{I} - T\} \) where \( 0 \leq T \leq \mathbb{I} \); When the measurement outcome is \( T \) he infers that the state is \( \rho \), and otherwise it is \( \sigma \). Adopting the nomenclature from classical hypothesis testing, we refer to \( T \) as a test. The probability that Bob correctly guesses the state to be \( \rho \) is then equal to tr\((T\rho)\), whereas his probability of correctly guessing the state to be \( \sigma \) is tr\((\mathbb{I} - T\sigma)\). Bob can erroneously infer the state to be \( \sigma \) when it is actually \( \rho \) or vice versa. The corresponding error probabilities are referred to as the Type I error and Type II error, respectively, and are given as follows:
\[
    \alpha(T) := \text{tr}(\mathbb{I} - T\rho), \quad \beta(T) := \text{tr}(T\sigma),
\]
Correspondingly, if multiple (say, \( n \)) identical copies of the system are available, and a test \( T_n \in \mathcal{B}(\mathcal{H}^{\otimes n}) \) is performed on the \( n \) copies, then the Type I and Type II errors are given by
\[
    \alpha_n(T_n) := \text{tr}(\mathbb{I}_n - T_n \rho^{\otimes n}), \quad \beta_n(T_n) := \text{tr}(T_n \sigma^{\otimes n}),
\]
where \( \mathbb{I}_n \) denotes the identity operator in \( \mathcal{B}(\mathcal{H}^{\otimes n}) \). There is a trade-off between the two error probabilities and there are various ways to optimize them. In the setting of asymmetric quantum hypothesis testing, one minimizes the Type II error under the constraint that the Type I error stays below a threshold value \( \varepsilon \in (0, 1) \). In this case one is interested in minimizing the following quantity
\[
    \beta_{n,\varepsilon} := \min \{ \beta_n(T_n) : \alpha_n(T_n) \leq \varepsilon, \ 0 \leq T_n \leq \mathbb{I}_n \}, \quad (45)
\]
where the infimum is taken over all possible tests \( T_n \in \mathcal{B}(\mathcal{H}^{\otimes n}) \). The quantum Stein lemma [19, 35] states that
\[
    \lim_{n \to \infty} \left( -\frac{1}{n} \log \beta_{n,\varepsilon} \right) = D(\rho || \sigma).
\]
The asymptotic strong converse rate $R_{sc}$ of the above quantum hypothesis testing problem is defined to be the smallest number $R$ such that if
\[
\limsup_{n \to \infty} \frac{1}{n} \log \beta_n(T_n) \leq -R,
\]
for some sequence of tests $\{T_n\}_{n \in \mathbb{N}}$, then
\[
\lim_{n \to \infty} \alpha_n(T_n) = 1.
\]
This quantity has been shown to be equal to Stein’s exponent $D(\rho||\sigma)$. In this section we are interested in obtaining a bound on the strong converse rate in the finite blocklength regime, that is when Bob receives a finite number of identical copies of the quantum system. We use reverse hypercontractivity in order to obtain our bound. Before stating and proving the main theorem of this section, we recall the following important inequality that will be used in the proof.

**Lemma 28** (Araki-Lieb-Thirring inequality [24, 2]). For any $A, B \in \mathcal{P}(\mathcal{H})$, and $r \in [0, 1]$,
\[
\text{tr}(B^{r/2}A^r B^{r/2}) \leq \text{tr}(B^{1/2}AB^{1/2})^r.
\]

Our main result, from which a bound for the finite blocklength strong converse rate follows directly as a corollary, is given by Theorem 29.

**Theorem 29.** Let $\rho, \sigma \in \mathcal{D}_n(\mathcal{H})$ being faithful density matrices\(^8\). Then for any test $0 \leq T_n \leq \mathbb{1}_n$, where $T_n \in \mathcal{B}(\mathcal{H}^{\otimes n})$
\[
\log \text{tr}(\sigma^{\otimes n} T_n) \geq -nD(\rho||\sigma) - 2 \sqrt{n\|\rho - 1\|_\infty \log \frac{1}{\text{tr}(\rho^{\otimes n} T_n)}} + \log \text{tr}(\rho^{\otimes n} T_n).
\]

**Proof.** For simplicity of notation we will use $\sigma_n := \sigma^{\otimes n}$ and $\rho_n := \rho^{\otimes n}$. Let $0 \leq p, q \leq 1$ and let $t \geq 0$ be such that
\[
(1 - p)(1 - q) = e^{-t}.
\]
Let $\mathcal{L}$ denote the generator of a generalized depolarizing semigroup $\{\Phi_t : t \geq 0\}$ with invariant state $\rho$, i.e., $\Phi_t(X) = e^{-t} X + (1 - e^{-t}) \text{tr}(\rho X) \mathbb{1}$. By Theorem 19 the 1-log-Sobolev constants of this semigroup and its tensor powers are lower bounded by $1/4$. Then using Lemma 18 for $Y = T_n$ and $X = \Gamma_{\rho_n}^{-1}(\sigma_n)$ we obtain
\[
\text{tr}(\sigma_n \Phi_t^{\otimes n}(T_n)) \geq \|\Gamma_{\rho_n}^{-1}(\sigma_n)\|_{p, \rho_n} \|T_n\|_{q, \rho_n}.
\]

An application of the Araki-Lieb-Thirring inequality, Lemma 28 with $A = \sigma_n$, $B = \rho_n^{(1-p)/p}$ and $r = p \in [0, 1]$ leads to
\[
\|\Gamma_{\rho_n}^{-1}(\sigma_n)\|_{p, \rho_n} = \left[\text{tr}\left(\rho_n^{(1-p)/2p} \sigma_n \rho_n^{(1-p)/2p}\right)\right]^{1/p} \geq \left[\text{tr}\left(\rho_n^{1-p} \sigma_n^p\right)\right]^{1/p} = \exp(-D_{1-p}(\rho_n||\sigma_n)),
\]
where
\[
D_{1-p}(\rho||\sigma) := \frac{1}{p} \log \text{tr}(\rho \sigma^{1-p}),
\]
denotes the quantum Rényi divergence between $\rho$ and $\sigma$. A very similar application of Lemma 28 for $A = T_n$ and $B = \rho_n^{1/q}$ and $r = q \in [0, 1]$ yields
\[
\|T_n\|_{q, \rho_n} = \left[\text{tr}\left(\rho_n^{1/2q} T_n \rho_n^{1/2q}\right)^q\right]^{1/q} \geq \left[\text{tr}(\rho_n T_n^q)\right]^{1/q} \geq \left[\text{tr}(\rho_n T_n)\right]^{1/q},
\]
\(^8\)What we really need is that the supports of $\rho$ and $\sigma$ being the same (and not being the whole $\mathcal{H}$) since in this case we may restrict everything to this support.
where in the last inequality, we used that $0 \leq T_n \leq 1$, so that $T_n^q \geq T_n$. Using the last two bounds in (48), we get
\[
\text{tr}(\sigma_n \Phi_t^{\otimes n}(T_n)) \geq [\text{tr}(\rho_n T_n)]^{1/q} \exp \left(-D_{1-p}(\rho_n || \sigma_n)\right).
\]

Taking the limit $p \to 0$ (and $q \to 1 - e^{-t}$) on both sides of the above inequality yields
\[
\text{tr}(\sigma_n \Phi_t^{\otimes n}(T_n)) \geq [\text{tr}(\rho_n T_n)]^{1/(1-e^{-t})} \exp \left(-D(\rho_n || \sigma_n)\right). \quad (49)
\]

Let $\gamma := \|\rho \sigma^{-1}\|_\infty$ and define the superoperator $\Psi_t$ by
\[
\Psi_t(X) = e^{-t} I + \gamma (1 - e^{-t}) \text{tr}(\sigma X) I.
\]

Then by induction on $n$ it can be shown that $\Psi_t^{\otimes n} - \Phi_t^{\otimes n}$ is a completely positive superoperator. This is clear from definitions for $n = 1$, and for every $Y \in \mathcal{P}(H^{\otimes n} \otimes H')$, where $H'$ is an arbitrary Hilbert space, we have
\[
\Psi_t^{\otimes n} \otimes \mathcal{I}(Y) = (\Psi^{\otimes (n-1)} \otimes \mathcal{I}) (\mathcal{I}^{\otimes (n-1)} \otimes \Psi_t \otimes \mathcal{I}(Y))
\geq (\Phi^{\otimes (n-1)} \otimes \mathcal{I}) (\mathcal{I}^{\otimes (n-1)} \otimes \Psi_t \otimes \mathcal{I}(Y))
\geq (\mathcal{I}^{\otimes (n-1)} \otimes \Psi_t \otimes \mathcal{I}) (\Phi^{\otimes (n-1)} \otimes \mathcal{I} \otimes \mathcal{I}(Y))
= \Phi_t^{\otimes n} \otimes \mathcal{I}(Y),
\]

where in the inequalities come from the induction hypothesis and the base of induction. Therefore, $\Psi_t^{\otimes n} - \Phi_t^{\otimes n}$ is a completely positive. On the other hand, for every $Y \in \mathcal{B}(H^{\otimes n})$ we have
\[
\text{tr}(\sigma_n \Psi_t^{\otimes n}(Y)) = (e^{-t} + \gamma (1 - e^{-t}))^n \text{tr}(\sigma_n Y).
\]

This equation is immediate for $n = 1$, and for arbitrary $n$ can be proven by first observing that it holds for $Y = Y_1 \otimes \cdots \otimes Y_n$ being of a tensor product form, and then using linearity. Putting these together we arrive at
\[
\text{tr}(\sigma_n \Phi_t^{\otimes n}(T_n)) \leq \text{tr}(\sigma_n \Psi_t^{\otimes n}(T_n))
= (e^{-t} + \gamma (1 - e^{-t}))^n \text{tr}(\sigma_n T_n).
\]

Next using $\gamma \geq 1$, the convexity of $h(x) = x^\gamma$ implies $(h(x) - h(1))/(x - 1) \geq h'(1)$ for every $x \geq 1$. Therefore, $e^{\gamma t} - 1 \geq \gamma (e^t - 1)$ for every $t \geq 0$, and $e^{-t} + \gamma (1 - e^{-t}) \leq e^{(\gamma - 1)t}$. As a result
\[
\text{tr}(\sigma_n \Phi_t^{\otimes n}(T_n)) \leq e^{(\gamma - 1)nt} \text{tr}(\sigma_n T_n). \quad (50)
\]

Then from (49) and (50) we get
\[
[\text{tr}(\rho_n T_n)]^{1/(1-e^{-t})} \exp \left(-D(\rho_n || \sigma_n)\right) \leq e^{(\gamma - 1)nt} \text{tr}(\sigma_n T_n).
\]

Taking the logarithm of both sides yields
\[
\log \text{tr}(\sigma_n T_n) \geq -D(\rho_n || \sigma_n) - (\gamma - 1)nt + \frac{1}{1 - e^{-t}} \log \text{tr}(\rho_n T_n)
\geq -D(\rho_n || \sigma_n) - \gamma nt + \left(1 + \frac{1}{t}\right) \log \text{tr}(\rho_n T_n), \quad (51)
\]

where the second inequality follows from $e^t \geq 1 + t$ and
\[
\frac{1}{1 - e^{-t}} = 1 + \frac{1}{e^t - 1} \leq 1 + \frac{1}{t}.
\]

Optimizing (51) over the choice of $t$ and letting
\[
t = \left(\frac{-\log \text{tr}(\rho_n T_n)}{\gamma n}\right)^{1/2},
\]

26
we obtain the desired inequality
\[
\log \text{tr}(\sigma_n T_n) \geq -nD(\rho\|\sigma) - 2\sqrt{-\gamma n \log \text{tr}(\rho_n T_n)} + \log \text{tr}(\rho_n T_n).
\]

**Corollary 30** (Finite-blocklength strong converse bound for quantum hypothesis testing). Let \(\rho, \sigma \in \mathcal{D}_+(\mathcal{H})\) and \(\gamma = \|\rho \sigma^{-1}\|_\infty\). Then for any test \(0 \leq T_n \leq \mathbb{I}_n\), where \(T_n \in \mathcal{B}(\mathcal{H}^\otimes n)\), if the Type II error satisfies the inequality \(\beta_n(T_n) \leq e^{-nr} \text{ for } r > D(\rho\|\sigma)\), then the Type I error satisfies
\[
\alpha_n(T_n) \geq 1 - e^{-nf},
\]
where
\[
f = \left( \sqrt{\gamma + (r - D(\rho\|\sigma))} - \sqrt{\gamma} \right)^2,
\]
tends to zero in the limit of \(r \to D(\rho\|\sigma)\).

**Proof.** From Theorem 29 and the condition \(\beta_n(T_n) \leq e^{-nr}\) for \(r > D(\rho\|\sigma)\) we have
\[
-nr \geq -nD(\rho\|\sigma) - 2\sqrt{n \gamma \log \frac{1}{1 - \alpha_n(T_n)}} - \log \frac{1}{1 - \alpha_n(T_n)}.
\]
Defining \(x_n^2 := \log \frac{1}{1 - \alpha_n(T_n)}\), this is equivalent to
\[
x_n^2 + 2\sqrt{n \gamma x_n} - n (r - D(\rho\|\sigma)) \geq 0,
\]
solving which directly leads to the statement of the corollary. □

Theorem 29 also leads to the following finite blocklength second order lower bound on the Type II error when the Type I error is less than a threshold value.

**Corollary 31.** Let \(\rho, \sigma \in \mathcal{D}_+(\mathcal{H})\). Then for any \(n \in \mathbb{N}\) and \(\varepsilon > 0\) the Type II error satisfies
\[
\beta_{n,\varepsilon} \geq (1 - \varepsilon) \exp \left( -nD(\rho\|\sigma) - 2\sqrt{n \gamma \log \left( \frac{1}{1 - \varepsilon} \right)} \right),
\]
where \(\gamma = \|\rho \sigma^{-1}\|_\infty\).

A lower bound on \(\beta_{n,\varepsilon}\) was also obtained by different means by Audenaert, Mosonyi and Verstraete in Theorem 3.3 of [3].

### 5.2 Classical-quantum channels

The strong converse property of the capacity of a c-q channel was proved independently in [34, 44]. In this section, we use the quantum reverse hypercontractivity inequality to obtain a finite blocklength strong converse bound for transmission of information through classical-quantum (c-q) channels. Suppose Alice wants to send classical messages belonging to a finite set \(\mathcal{M}\) to Bob, using a memoryless c-q channel:
\[
\mathcal{W} : \mathcal{X} \to \mathcal{D}(\mathcal{H}_B),
\]
where \(\mathcal{X}\) denotes a finite alphabet, and \(\mathcal{H}_B\) is a finite-dimensional Hilbert space with dimension \(d\). Thus the output of the channel under input \(x \in \mathcal{X}\) is some quantum state \(\rho_x = \mathcal{W}(x) \in \mathcal{D}(\mathcal{H}_B)\). To send a message \(m \in \mathcal{M}\), Alice encodes it in a codeword
\[
\mathcal{E}^n(m) = x^n(m) \equiv (x_1, x_2, \ldots, x_n) \in \mathcal{X}^n,
\]
where \(\mathcal{E}^n\) denotes the encoding map. She then sends it to Bob through \(n\) successive uses of the channel \(\mathcal{W}^\otimes n\), whose action on the codeword \(x^n\) is given by
\[
\mathcal{W}^\otimes n(x^n) = \rho_{x_1} \otimes \cdots \otimes \rho_{x_n} \equiv \rho_{x^n}.
\]
In order to infer Alice’s message, Bob applies a measurement, described by a POVM $\Pi^n := \{\Pi_{m}^{n}\}_{m \in \mathcal{M}}$ on the state $W^\otimes n(x^n) = \rho_{x^n}$ that he receives. The outcome of the measurement would be Bob’s guess of Alice’s message. See Figure 1.

The triple $(|\mathcal{M}|, \mathcal{E}^n, \Pi^n)$ defines a code which we denote as $C_n$. The rate of the code is given by $\log |\mathcal{M}|/n$, and its maximum probability of error is given by

$$p_{\text{max}}(C_n; W) := \max_{m \in \mathcal{M}} 1 - \text{tr}(\Pi_{m}^{n} W^\otimes n \circ \mathcal{E}^n (m)).$$

We let $C_{n,\varepsilon}(W)$ be the maximum rate $\log |\mathcal{M}|/n$ over all codes $C_n = (|\mathcal{M}|, \mathcal{E}^n, \Pi^n)$ with $p_{\text{max}}(C_n; W) \leq \varepsilon$. Then the (asymptotic) capacity of the channel is defined by

$$C(W) := \lim_{\varepsilon \to 0} \lim_{n \to \infty} C_{n,\varepsilon}(W).$$

For c-q channels, the capacity is given by

$$C(W) = \max_{P_X} I(X; B)_\rho.$$ 

Here the maximum is taken over all probability distributions $P_X$ on $\mathcal{X}$, the bipartite state $\rho_{XB}$ is given by

$$\rho_{XB} = \sum_{x \in \mathcal{X}} P_X(x) |x⟩⟨x| \otimes \rho_x,$$

and $I(X; B)_\rho = D(\rho_{XB} || P_X \otimes \rho_B)$ is the mutual information function. The fact that the capacity is given by maximum mutual information is indeed implied by its additivity [38]. That is, the maximum mutual information associated to the channel $W^\otimes n$ equals $n$ times the maximum mutual information of $W$:

$$\max_{P_X} I(X^n; B^n) = n \max_{P_X} I(X; B) = nC(W). \quad (53)$$

**Theorem 32.** Let $W : \mathcal{X} \to \mathcal{D}(\mathcal{H}_B)$ be a c-q channel with $W(x) = \rho_x$ being faithful for all $x \in \mathcal{X}$. Then, for any code $C_n = (|\mathcal{M}|, \mathcal{E}^n, \Pi^n)$ with $p_{\text{max}}(C_n; W) \leq \varepsilon$ we have

$$I(X^n; B^n) \geq \log |\mathcal{M}| - 2 \sqrt{dn \log \frac{1}{1 - \varepsilon}} - \log \frac{1}{1 - \varepsilon},$$

where $d = \dim \mathcal{H}_B$ and the mutual information is computed with respect to

$$\rho_{X^n B^n} = \frac{1}{|\mathcal{M}|} \sum_{m} |x^n(m)⟩⟨x^n(m)| \otimes \rho_{x^n(m)}.$$ 

This theorem together with the additivity result [53] directly imply that for any code of rate larger than $C(W)$, the maximum probability of error goes to one, as $n \to \infty$.

**Proof.** For every $x^n = (x_1, \ldots, x_n) \in \mathcal{X}^n$ let $\Phi_{t,x^n} = \Phi_{t,x_1} \otimes \cdots \otimes \Phi_{t,x_n}$ with

$$\Phi_{t,x}(X) = e^{-t} X + (1 - e^{-t}) \text{tr}(\rho_x X).$$

Then following similar steps as in the proof of Theorem 29 using Theorem 19, Lemma 15 and the Araki-Lieb-Thirring inequality, for every $\Pi^n_{m}$, we have

$$\text{tr}(\rho_{B^n} \Phi_{t,x^n}(\Pi^n_{m})) \geq \left[\text{tr}(\rho_{x^n} \Pi^n_{m})\right]^{1/(1 - e^{-t})} e^{- D(\rho_{B^n} || \rho_{B^n})}.$$
Letting $x^n = x^n(m)$, using $\text{tr}(\rho_{x^n(m)}\Pi^n_m) \geq 1 - \varepsilon$, taking logarithm of both sides and averaging over the choice of $m \in \mathcal{M}$ we obtain

$$
\frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} \log \text{tr}(\rho_B \cdot \Phi_{t,x^n(m)}(\Pi^n_m)) \geq - \frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} D(\rho_{x^n(m)}\|\rho_B) + \frac{1}{1 - e^{-t}} \log(1 - \varepsilon)
$$

$$
= - I(X^n; B^n) + \frac{1}{1 - e^{-t}} \log(1 - \varepsilon)

\geq - I(X^n; B^n) + \left(1 + \frac{1}{t}\right) \log(1 - \varepsilon).
$$

Now define $\Psi_t(X) = e^{-t}X + (1 - e^{-t})\text{tr}(X)I$. Following similar steps as in the proof of Theorem 29 using $\rho_x \leq I$ it can be shown that $\Psi^n_t - \Phi_{t,x^n(m)}$ is complexity positive. Therefore, $\Phi_{t,x^n(m)}(\Pi^n_m) \leq \Psi^n_t(\Pi^n_m)$ and we have

$$
-I(X^n; B^n) + \left(1 + \frac{1}{t}\right) \log(1 - \varepsilon) \leq \frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} \log \text{tr}(\rho_B \cdot \Psi^n_t(\Pi^n_m))
$$

$$
\leq \log \left( \frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} \text{tr}(\rho_B \cdot \Psi^n_t(\Pi^n_m)) \right)

= \log \left( \frac{1}{|\mathcal{M}|} \text{tr}(\rho_B \cdot \Psi^n_t(\Pi^n_m)) \right),
$$

where the second line follows from the concavity of the logarithm function and in the third line we use the fact that $\{\Pi^n_m : m \in \mathcal{M}\}$ is a POVM. On the other hand,

$$
\Psi^n_t(\Pi^n_B) = (e^{-t} + (1 - e^{-t})d)^n \Pi^n_B \leq e^{(d-1)nt} \Pi^n_B
$$

Therefore,

$$
-I(X^n; B^n) + \left(1 + \frac{1}{t}\right) \log(1 - \varepsilon) \leq - \log |\mathcal{M}| + dnt.
$$

Optimizing over the choice of $t > 0$, the desired result follows. \qed

### A Proof of Proposition 7

(i) As mentioned in [12] (and explicitly worked out in [4]) for $p \geq 1$, contractivity can be proven using the Riesz-Thorin interpolation theorem. So we focus on $p \in (-\infty, -1] \cup [1/2, 1)$. First let $p = -q \in (-\infty, -1]$, and $X > 0$. We note that

$$
\|\Phi_t(X)\|_{p,\sigma} = \|\Phi_t(X)^{-1}\|_{q^{-1},\sigma}.
$$

On the other hand, $\Phi_t$ is completely positive and unital, and $z \mapsto z^{-1}$ is operator convex. Therefore, $\Phi_t(X^{-1}) \geq \Phi_t(X)^{-1}$ and $\|\Phi_t(X^{-1})\|_q \leq \|\Phi_t(X^{-1})\|_{q^{-1}}$. We conclude that

$$
\|\Phi_t(X)\|_{p,\sigma} \geq \|\Phi_t(X^{-1})\|_{q^{-1},\sigma} \geq \|X^{-1}\|_{q^{-1},\sigma} = \|X\|_{p,\sigma},
$$

where for the second inequality we use $q$-contractivity of $\Phi_t$ for $q \geq 1$.

Now suppose that $p \in [1/2, 1)$. We note that $\tilde{p} = (-\infty, -1]$, and that $\Phi_t$ is $\tilde{p}$-contractive. Then using Hölder’s duality, for $X > 0$ we have

$$
\|\Phi_t(X)\|_p = \inf_{Y > 0, \|Y\|_{p,\sigma} \geq 1} \langle Y, \Phi_t(X) \rangle_{\sigma}
$$

$$
= \inf_{Y > 0, \|Y\|_{p,\sigma} \geq 1} \langle \Phi_t(Y), X \rangle_{\sigma}
$$

$$
\geq \inf_{Z > 0, \|Z\|_{p,\sigma} \geq 1} \langle Z, X \rangle_{\sigma}

= \|X\|_{p,\sigma}.
$$

Here the first equality follows from Lemma [6] and the inequality follows from the $\tilde{p}$-contractivity of $\Phi_t$, i.e., $\|\Phi_t(Y)\|_{\tilde{p},\sigma} \geq \|Y\|_{\tilde{p},\sigma} \geq 1$.

(ii) As worked out in [10] this is an immediate consequence of the operator Jensen inequality.
B Second proof of Theorem \[14\]

The proof is very similar to the one used in [4] to prove the strong $L_p$-regularity of the Dirichlet forms. Before stating the proof we need some definitions.

For a compact set $I$ we let $C(I)$ to be the Banach space of continuous, complex valued functions on $I$ (equipped with the supremum norm). Then the Banach space $C(I \times I)$ becomes a $*$-algebra when endowed with the natural involution $f \mapsto f^*$ with $f^*(x,y) = f(x,y)$. Thus $C(I \times I)$ is a $C^*$-algebra.

We endow $B(\mathcal{H})$ with a Hilbert space structure by equipping it with the Hilbert-Schmidt inner product:

$$\langle X,Y \rangle_{HS} := \text{tr}(X^\dagger Y).$$

Fix $X,Y \in B_{sa}(\mathcal{H})$, and let $I$ be a compact interval containing the spectrum of both $X$ and $Y$. We define a $*$-representation $\pi_{X,Y} : C(I \times I) \to B(\mathcal{H})$ that is uniquely determined by its action on tensor products of functions as follows. For $f,g \in C(I)$ we define $\pi_{X,Y}(f \otimes g) \in B(\mathcal{H})$ by

$$\pi_{X,Y}(f \otimes g)(Z) = f(X)Zg(Y), \quad Z \in B(\mathcal{H}).$$

The following lemma can be found in [4] (see Lemma 4.2):

**Lemma 33.** $\pi_{X,Y}$ is a $*$-representation between $C^*$-algebras. That is,

(i) $\pi_{X,Y}(1) = I$, where $1$ is the constant function on $I \times I$ equal to $1$.

(ii) $\pi_{X,Y}(f^* g) = \pi_{X,Y}(f)^* \pi_{X,Y}(g)$ for all $f,g \in C(I \times I)$.

(iii) If $f \in C(I \times I)$, is a non-negative function, then $\pi_{X,Y}(f)$ is a positive semi-definite operator on $B(\mathcal{H})$ for the Hilbert-Schmidt inner product, i.e., $\pi_{X,Y}(f) \in \mathcal{P}(B(\mathcal{H}))$.

Now, for any function $f \in C(I)$, define $\tilde{f}$ to be the function in $C(I \times I)$ defined by

$$\tilde{f}(s,t) = \begin{cases} f(s) - f(t) & s \neq t \\ f'(s) & s = t. \end{cases}$$

(54)

The following lemma, proved in [4] (see Lemma 4.2), gives a generalization of the chain rule formula to a derivation.

**Lemma 34.** Let $X,Y \in B_{sa}(\mathcal{H})$ and let $I$ be a compact interval containing the spectrums of $X,Y$. Let $f \in C(I)$ be a continuously differentiable function such that $f(0) = 0$. Then for all $V \in B(\mathcal{H})$ we have

$$V f(Y) - f(X)V = \pi_{X,Y}(\tilde{f})(V Y - X V),$$

where $\tilde{f}$ is defined (54).

We can now prove the theorem. By the result of [9] (an extension of Lemma [13]), there are superoperators $\partial_j : B(\mathcal{H}) \to B(\mathcal{H})$ of the form

$$\partial_j(X) = [V_j, X] = V_j X - X V_j,$$

where $V_j \in B(\mathcal{H})$, such that

$$\langle X, L(Y) \rangle_\sigma = \sum_j \langle \partial_j X, \partial_j Y \rangle_\sigma.$$  

(55)

Moreover, $V_j$’s are such that there are $\omega_j \geq 0$ with

$$\sigma V_j = \omega_j V_j \sigma.$$

Using the above equation one can show [4] that

$$\partial_j(I_{\sigma, p}(X)) = \Gamma_{\sigma}^{-\frac{1}{p}}\left(V_j \left(\Gamma_{\sigma}^{\frac{1}{p}}(\omega_j^{-\frac{1}{p}}X)\right)^{\frac{1}{p}} - \left(\Gamma_{\sigma}^{\frac{1}{p}}(\omega_j^{\frac{1}{p}}X)\right)^{\frac{1}{p}} V_j \right).$$

(56)
For arbitrary $X > 0$ define $Y_j := \omega_j^{-1/4} \Gamma_{\sigma}^{\frac{1}{4}}(X)$ and $Z_j := \omega_j^{1/4} \Gamma_{\sigma}^{\frac{1}{4}}(X)$. Using (56) we compute

\[
\mathcal{E}_{q,\mathcal{L}}(I_{q,2}(X)) = \frac{q^2}{4} \langle I_{q,2}(I_{q,2}(X))\rangle_{\sigma} \mathcal{L}(I_{q,2}(X)) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \frac{q^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

where in (57) we used (56), in (58) we used (55), and in (59) we used the chain rule formula of Lemma 33 for the functions $f_a$ with $f_a(x) = x^a$. Finally, in (60) we used part (ii) of Lemma 33.

Now, using the proofs of Theorem 2.1 and Lemma 2.4 of [29], for any $x, y \geq 0$ and $0 \leq p \leq q \leq 2$ we have

\[
q^2(x^{1/q} - y^{1/q})(x^{1/q} - y^{1/q}) \leq p^2(x^{1/p} - y^{1/p})(x^{1/p} - y^{1/p}).
\]

This means that for all $x, y$ we have

\[
q^2(\hat{f}_{2/q} \hat{f}_{2/q})(x, y) \leq p^2(\hat{f}_{2/p} \hat{f}_{2/p})(x, y).
\]

Hence, by part (iii) of Lemma 33 we have

\[
\mathcal{E}_{q,\mathcal{L}}(I_{q,2}(X)) \leq \frac{p^2}{4} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma} \sum_j \langle \partial_j I_{q,2}(X) \rangle_{\sigma}
\]

\[
= \mathcal{E}_{p,\mathcal{L}}(I_{p,2}(X)).
\]
