Abstract: Previously, we demonstrated that caulerpine has spasmolytic effect on guinea pig ileum. The aim of this study was to investigate pathways of its spasmolytic action. We test caulerpine against phasic contractions induced by carbachol in the circular layer of guinea pig ileum and this alkaloid did not inhibit these contractions, indicating that caulerpine did not interfering with the mobilization of Ca2+ from intracellular stores. Additionally, the spasmolytic effect of caulerpine did not involve K+ channels. Furthermore, we observed that α2- adrenergic receptors were not involved in the spasmolytic effect of caulerpine, since the relaxation curve induced by caulerpine was not shifted in the presence of yohimbine (α2-adrenergic antagonist). However, in the presence of propranolol (β-adrenergic antagonist), the relaxation curve induced by caulerpine was right-shifted, resulting in a fivefold increase in EC50. Thus, a possible mechanism for the spasmolytic action of caulerpine is the activation of β-adrenergic receptors.

Keywords: caulerpine; spasmolytic effect; adrenergic receptors; guinea pig ileum.
**Experimental**

**Caulerpine Isolation**

The isolation was performed as previously described (Cavalcante-Silva et al. 2013). *Caulerpa sertularioides* and *C. mexicana* algae were collected from the coastal region of Cabo Branco, João Pessoa, Paraíba State, Brazil in March 2009. The specimens were identified by Dr. George Emmanuel Cavalcanti de Miranda. Voucher specimens of *C. sertularioides* (JPB 13983) and *C. mexicana* (JPB 13985) have been deposited in the Lauro Pires Xavier Herbarium at the Federal University of Paraíba, Brazil. The algae were extracted with MeOH at room temperature and the extract was partitioned between hexane, dichloromethane, ethyl acetate and methanol. In the ethyl acetate phase there was precipitation of an orange-red pigment. On the basis of its NMR spectral data and chemical properties, it was assigned the structure of 5,12-dihydro-cycloocta [1,2-b;5,6-b′]diindole-6,13-dicarboxylic acid dimethyl ester, named caulerpine or caulerpin. The caulerpine showed 99.4% purity in HPLC analysis as previously described (Cavalcante-Silva et al. 2014).

**Solutions and Drugs**

Caulerpine was dissolved in Cremophor® and diluted in distilled water. Carbamoylcholine chloride (carbachol - CCh), cesium chloride (CsCl), yohimbine hydrochloride and propranolol hydrochloride were purchased from Sigma-Aldrich (St. Louis, MO, USA) and were dissolved and diluted in distilled water. The physiological solution was a freshly modified Krebs solution (pH 7.4) with the following composition (mM): NaCl (117.0), KCl (4.7), MgSO₄ (1.3), NaH₂PO₄ (1.2), CaCl₂ (2.5), glucose (11.0) and NaHCO₃ (25.0). These salts were obtained from Vetec (Rio de Janeiro, RJ, Brazil) and Fmaia (Cotia, SP, Brazil).

**Animals**

Adult guinea pigs (*Cavia porcellus*) of both sexes from the Professor Thomas George Bioterium of CBIotec/UFPB, weighing 368 ± 8 g, were used. The animals had free access to food and water and were kept in rooms at 21 ± 1°C with a 12-h light–dark cycle, and they were fasted for 18 h before the experiments. Measures were taken to reduce pain, stress and any suffering, in accordance with the ethical guidelines for animal use. All experimental procedures were previously approved and performed in accordance with the guidelines of the Research Ethics Committee of the Federal University of Alagoas (UFAL) (protocol CEUA 039/2012).

**Measurement of Contraction of Guinea Pig Ileum**

Animals were euthanized by cervical dislocation and bled. The distal ileum was immediately removed, cleaned of adhering fat and connective tissue, immersed in modified Krebs solution at room temperature and continuously gassed with carbogen (95% O₂ and 5% CO₂). Segments of the ileum (2–3 cm in length) oriented along the longitudinal muscle axis or circular muscle axis were suspended in a 5-mL organ bath containing modified Krebs solution and maintained under resting load of 1.0 g at 37°C. An isometric transducer (FORT-10) coupled to an amplifier (TMB4M), both from World Precision Instruments (USA) was connected to an analog/digital converter board (Bio Data, Brazil) installed in a computer with BioMed© software version RV2 and used to record isometric contractions.

**Pharmacological Experiments**

**Effect of the Caulerpine on CCh-Induced Phasic Contractions in Circular Muscle Layer**

After a stabilization period (120 min), two phasic contractions were obtained by 10⁻⁶ M CCh with intervals of 15 min between them. Caulerpine was then added, and after an incubation period of 15 min, a third
concentration-response curve was obtained in the presence of $10^{-4}$ and $3 \times 10^{-4}$ M caulerpine in different preparations.

**Effect of Caulerpine on CCh-induced Tonic Contractions in the Absence and Presence of Non-selective Potassium Channel Blocker (CsCl)**

After a stabilization period (30 min), an isometric contraction was elicited by $10^{-5}$ M CCh. Contractile agents remained in contact with the preparation until a contraction plateau was reached (approximately 10 min). Caulerpine was added cumulatively ($10^{-7}$ up to $10^{-3}$ M) at the plateau phase, to obtain a relaxation curve (control). Afterwards, preparations were washed out and 5 mM CsCl (Cecchi et al. 1987), a non-selective potassium channel blocker, was added to the preparations for exposure of 20 min. Other tonic contractions were then elicited in the presence of the blocker, and caulerpine was cumulatively added. Relaxation was expressed as percent reversal of initial contraction elicited by the contractile agents. The molar concentration of a substance that produces 50% of its maximal effect (EC$_{50}$) was obtained graphically from the concentration-response curves (Neubig et al. 2003). The relaxant potency of caulerpine was evaluated by comparing EC$_{50}$ values in the absence and presence of the blocker.

**Effect of Caulerpine on CCh-induced Tonic Contractions in the Absence and Presence of Adrenergic Antagonists**

CCh-induced isometric contractions were obtained as described above. Afterwards, preparations were washed out and 1.3 μM yohimbine, an antagonist of $\alpha_2$ adrenergic receptors (Fagbemi & Salako 1982), or 5 μM propranolol, an antagonist of $\beta$ adrenergic receptors (Bauer 1982), was added in different preparations for exposure of 20 min. Other tonic contractions were elicited in the presence of the antagonists, and caulerpine was cumulatively added. Relaxation was expressed as percent reversal of initial contraction elicited by the contractile agents. The relaxant potency of caulerpine was evaluated by comparing EC$_{50}$ values in the absence and presence of the antagonists.

**Statistical Analysis**

Data are expressed as means and S.E.M. EC$_{50}$ values were determined by nonlinear regression (Neubig et al. 2003). Differences between means were statistically compared using a t-test or one-way ANOVA followed by Bonferroni’s test when appropriate. The significance level considered in all tests was $p < 0.05$. All values were obtained using Graph-Pad Prism® 5.01 software (GraphPad Software Inc., San Diego, CA, USA).
