Abstract

Baryons containing two heavy quarks are treated in the Born-Oppenheimer approximation. Schrödinger equation for two center Coulomb plus harmonic oscillator potential is solved by the method of ethalon equation at large intercenter separations. Asymptotical expansions for energy term and wave function are obtained in the analytical form. Using those formulas, the energy spectra of doubly heavy baryons with various quark compositions are calculated analytically.

Introduction

The investigation of properties of hadrons containing one or more heavy quarks is very important for understanding the dynamics of quark and gluon interactions. Presently at the LHC, B-factories and the Tevatron with high luminosity, several experiments have been proposed, in which a detailed study of baryons containing two heavy quarks can be performed. In particular, in the forthcoming experiment at CERN, the COMPASS group is going to find the doubly charmed baryons and study their physical properties. In this connection, doubly heavy quark baryons are now becoming one of the most exciting subjects in particle physics. Therefore, theoretical predictions of properties of doubly heavy quark baryons acquire a big significance for the forthcoming experimental study of these particles.

So far there have been various approaches by which their mass spectra and other properties can be calculated. One of them is the nonrelativistic quark model which gives relatively accurate results for baryon spectra \[1, 2, 3].\]

The possible quark compositions of doubly heavy quark baryons are $ccq$, $cbq$ and $bbq$, where $q$ denotes a light $u$, $d$ or $s$ quark. Note that the baryons containing the top quark(s) are not practical subject here because a top quark is extremely heavy and hence we have no chance to find them as stable hadrons. The doubly heavy quark baryons may be considered as an analogue of the hydrogen molecular ion $H_2^+$, which has been treated successfully in the Born-Oppenheimer approximation. The same approximation is expected to be efficient even for doubly heavy quark baryons, though there exist some differences between these baryons and $H_2^+$ systems. One of them is, for this case, the appearance of the confining potential in addition to the QCD Coulomb potential. As is well known, the variables of the Schrödinger equation with two-center Coulomb plus confining potential cannot be separated for their kinematical variables, in general. To our
knowledge, the two-center potential which allows the separation of variables is only the two-center Coulomb plus harmonic oscillator potential.

In this paper, we treat $QQq$ baryons in the nonrelativistic approach by using the solution of the Schrödinger equation with two-center Coulomb plus harmonic oscillator potential, i.e. the well-known method of ethalon equation which is widely used for solving Schrödinger equation with two-center pure Coulomb potential in the physics of $H_2^+$ [4, 5, 6]. First, we give a general scheme of treatment $QQq$ baryon in the Born-Oppenheimer approximation. Then, the two-center Schrödinger equation with two-center Coulomb plus harmonic oscillator potential is analytically solved with some approximation: the energy term of the light quark moving in the field of two heavy quarks is obtained in the form of asymptotical expansion over the inverse power of the distance between heavy quarks. Finally, we give an analytical formula of the baryon energy spectrum for $QQq$.

**Doubly heavy quark baryon in the Born-Oppenheimer approximation**

In the Born-Oppenheimer approximation the wave function is split into heavy- and light-quark degrees of freedom

$$\Psi(R, r) = \sum_n \phi_n(R)\psi_n(R, r),$$

where $R$ is the distance between two heavy quarks and $r$ is the distance between light quark and center-of-mass of the heavy-quark pair. The light quark wave function $\psi(r, R)$ and its energy term $E(R)$ can be found from the Schrödinger equation

$$\left[-\frac{1}{2m_q}\Delta + V(r_1) + V(r_2)\right]\psi = E(R)\psi,$$

where $r_1$ and $r_2$ are the distances between light and heavy quarks, $Q_1$ and $Q_2$, respectively. The binding energy of this system is approximated by
the equation:
\[
\left[ -\frac{1}{2\bar{M}_{QQ}} \Delta + V_{QQ}(R) + E(R) \right] \phi = \varepsilon \phi,
\]
where \(\bar{M}_{QQ}\) is the reduced mass of \(QQ\).

A quark potential with Coulomb plus harmonic confinement for this baryon is given by [3]

\[
V(r_{ij}) = \sum_{i,j} \frac{1}{4} \lambda_i \lambda_j (V_0 - Ar_{ij}^2 + \frac{\alpha_s}{r_{ij}}) = -\frac{2}{3} \sum_{i,j} (V_0 - Ar_{ij}^2 + \frac{\alpha_s}{r_{ij}})
\]

In the field of two heavy quarks with this potential, the motion of a light quark can be nonrelativistically described by the following Schrödinger equation,

\[
\left[ -\frac{1}{2} \Delta - Z \frac{r_1}{r_1} - Z \frac{r_2}{r_2} + \omega^2 (r_1^2 + r_2^2) - \frac{4}{3} V_0 \right] \psi = E(R) \psi,
\]

where \(Z = 2\alpha_s/3\) and \(\omega^2 = 2A/3\).

In the prolate spheroidal coordinates defined as

\[
\xi = \frac{r_1 + r_2}{R} \quad (1 < \xi < \infty), \quad \eta = \frac{r_1 - r_2}{R} \quad (-1 < \eta < 1),
\]

the potential term in eq.(1) can be written in the form

\[
V(r_1, r_2) = -\frac{2}{R^2} \frac{a(\xi) + b(\eta)}{\xi^2 - \eta^2} + \frac{\omega^2 R^2}{2} - \frac{4}{3} V_0,
\]

where

\[
a(\xi) = 2ZR - \frac{\omega^2 R^4}{4} \xi^2 (\xi^2 - 1), \quad b(\eta) = 2ZR - \frac{\omega^2 R^4}{4} \eta^2 (\eta^2 - 1).
\]

As is well known[4], the Schrödinger equation with the potential in the form of eq.(2) is separable in the prolate spheroidal coordinates. Then it is convenient to use

\[
\psi = \frac{U(\xi)}{\sqrt{\xi^2 - 1}} \frac{V(\eta)}{\sqrt{1 - \eta^2}} \frac{e^{\pm im\phi}}{\sqrt{2\pi}},
\]

where \(\phi\) and \(m\) are azimuthal angle and azimuthal quantum number, respectively. After substituting this into eq.(1), we obtain from the following
ordinary differential equations connected with separation constants $\lambda$ and $m$:

$$U''(\xi) + \left[\frac{h^2}{4} + \frac{h(\alpha \xi - \lambda)}{\xi^2 - 1} - h^4 \gamma \xi^2 + \frac{1 - m^2}{(\xi^2 - 1)^2}\right]U(\xi) = 0,$$  \hspace{1cm} (3)

$$V''(\eta) + \left[\frac{h^2}{4} + \frac{h \lambda}{1 - \eta^2} - h^4 \gamma \eta^2 + \frac{1 - m^2}{(1 - \eta^2)^2}\right]V(\eta) = 0,$$  \hspace{1cm} (4)

where $\alpha = 2Z/\sqrt{2E'}$ and $\gamma = \omega^2/8E'^2$, and further

$$h = \sqrt{2E'R},$$  \hspace{1cm} (5)

with

$$E' = E - \frac{\omega^2 R^2}{2} + \frac{4}{3}V_0.$$  

Finiteness and continuity of the wave function $\psi$ in the whole space lead to the following boundary conditions for the functions $U$ and $V$:

$$U(\xi) \mid_{\xi=1} = 0, \quad U(\xi) \mid_{\xi \rightarrow \infty} \rightarrow 0,$$  \hspace{1cm} (6)

$$V(\eta) \mid_{\eta=\pm 1} = 0.$$  \hspace{1cm} (7)

**Asymptotics of quasi-angular equation**

We will approximately solve eqs.(3) and(4) for large $R$ by the method of ethalon equation. This method is successfully applied to the solution of nonrelativistic two center Coulomb problem \[4, 5, 6\] and in the theory of diffraction of waves. Details on the method of ethalon equation are given in \[4, 5, 6, 7\], also briefly described in Appendix.

Let us start from the angular equation of (4). As an ethalon equation for eq.(4), we choose the following Whittaker equation \[8\]:

$$W'' + \left[-\frac{h^4}{4} + \frac{h^2 k}{z} + \frac{1 - m^2}{4z^2}\right]W = 0$$  \hspace{1cm} (8)
and seek a solution in the form

$$V = [z'(\eta)]^{-\frac{1}{2}} M_{k,m}(h^2 z),$$  \hfill (9)

where \( M_{k,m}(h^2 z) \) is the solution (regular at zero) of eq.(8). Substituting (9) into (4) and taking into account (8), we get the following equation for \( z \):

$$\frac{z'^2}{4} - \gamma(x - 1)^2 - \frac{1}{h^2}(\frac{1}{4} + \frac{kz'^2}{z} - \frac{\lambda}{2x(1 - x/2)}) + \frac{\tau}{h^2}(\frac{1}{x^2(1 - x^2)} - \frac{z'^2}{z^2}) - \frac{1}{2h^2}\{z, x\} = 0,$$  \hfill (10)

where

$$\{z, x\} = -\frac{3}{2}(\frac{z''}{z'})^2 + \frac{z'''}{z'},$$

and \( \tau = \frac{1-m^2}{4}, x = 1 + \eta \).

Requirement of coincidence at the transition points [6, 7]

$$z(x) \big|_{x=0} = 0,$$

leads to the following "quantum condition"

$$\lambda = 2kz'(0) + \frac{2\tau}{h^2}[\frac{z''(0)}{z'(0)} - 1].$$  \hfill (11)

We will seek the solution of eq.(10) and eigenvalues \( \lambda \) in the form of the following asymptotical expansion:

$$z = \sum_{k=0}^{\infty} \frac{z_k}{h^k}, \quad \lambda = \sum_{k=0}^{\infty} \frac{\lambda_k}{h^k}.$$

Substitution of these expansions into (10) gives us the recurrence system of differential equations for \( z \):

$$z_0' = 2\gamma \frac{1}{2}(x - 1),$$

$$z_1' = 0,$$

$$z_2' = \frac{1}{2z_0} + \frac{2kz_0'}{2z_0} - \frac{(z_1')^2}{2z_0} - \frac{2\lambda_0}{z_0x(1 - x/2)} - \frac{z_2^2}{2}.$$
and for $\lambda$:

$$
\begin{align*}
\lambda_0 & = 2k z'_0(0), \\
\lambda_1 & = 2k z'_1(0), \\
\lambda_2 & = 2k z'_2(0) + 2\tau \left( \frac{z''_0(0)}{z'_1(0)} - 1 \right),
\end{align*}
$$

Solving these recurrence equations, we obtain

$$
\lambda^{(\eta)} = 4k \gamma_1^2 + \frac{2k \beta - 4\tau}{h^2} + O\left(\frac{1}{h^4}\right),
$$

(12)

for $\lambda$, and

$$
z = \gamma_1^2 x (2 - x) + \frac{1}{h^2} \beta \ln(1 - x) + O\left(\frac{1}{h^4}\right),
$$

(13)

for $z$.

From boundary conditions one can obtain for quantum number $k$[5, 6]:

$$
k = q + \frac{m + 1}{2},
$$

where $q = 0, 1, 2, \ldots$.

**Asymptotics of quasi-radial equation**

As an ethalon equation for eq.(3), we take the following equation:

$$
W'' + \left[ h^2 s - h^4 y^2 - \frac{4\tau + 3}{4 y^2} \right] W = 0,
$$

(14)

a solution of which is expressed by the confluent hypergeometric functions[8, 9]

$$
W = y^c e^{-\frac{h^4 y^2}{2}} F\left(\frac{s - 2c - 1}{4}, c + \frac{1}{2}, h^4 y^2\right),
$$

where $c = \frac{1 + \sqrt{m^2 + 3}}{2}$. 

7
Boundary condition (6) and properties of functions \( F \) give rise to the following expression for \( s \):

\[
s = 4n + \sqrt{m^2 + 3 + 2}.
\]

Substituting

\[
U = [y(\xi)]^{-\frac{1}{2}}W(y(\xi))
\]

into eq. (3), we obtain

\[
\frac{y^2 y'^2}{4} - \frac{\gamma \xi^2}{4} + \frac{1}{h^2} \left( \frac{1}{4} - \frac{\lambda}{\xi^2 - 1} \right) + \frac{1}{h^3} \frac{\alpha \xi}{\xi^2 - 1} + \frac{4\tau}{h^4} \frac{3 - 4\tau y'^2}{2h^4} - \frac{1}{2h^4} \{y, \xi\} = 0.
\]

(15)

After substitution of

\[
\phi = \frac{y^2(t)}{4},
\]

this equation can be reduced to the form

\[
\phi'^2 - \gamma(t+1) + \frac{1}{h^2} \left( \frac{1}{4} - (n+\frac{1}{2}) \phi'^2 \right) - \frac{\lambda}{\phi(t+2)} + \frac{1}{h^3} \frac{\alpha(t+1)}{t(t+2)} + \frac{\tau}{h^4} \left( \frac{\phi'^2}{\phi} - \frac{4}{t^2(t+2)^2} \right) - [\phi, t] = 0,
\]

(16)

where \( t = \xi - 1 \). The quantization condition which follows from \( \phi(x) = 0 \) is written in the form

\[
\lambda = -2s\phi'(0) + \frac{\alpha}{h} - \frac{1}{h^2} \left[ \frac{\phi''}{\phi'} + 1 \right]_{t=0}.
\]

(17)

Inserting the asymptotical expansions

\[
\phi = \sum_{k=0}^{\infty} \frac{\phi_k}{h^k}, \quad \lambda = \sum_{k=0}^{\infty} \frac{\lambda_k}{h^k}
\]

into eq. (16) and solving the equations obtained herewith, we get the following result

\[
y = 2\gamma^\frac{1}{4} (t^2 + 2t)^\frac{3}{4} + \frac{1}{h^2} \gamma^{-\frac{1}{4}} (t^2 + 2t)^{-\frac{1}{4}} \ln(t + 1) + \frac{1}{h^3} \alpha \gamma^{-\frac{3}{4}} (t^2 + 2t)^{-\frac{1}{4}} \ln \frac{2(t + 1)}{t + 1} + O(\frac{1}{h^4}),
\]

(18)

for \( y \), and

\[
\lambda(\xi) = -2s\gamma^\frac{1}{4} - \frac{\alpha}{h} + \frac{4\tau - s\delta}{h^2} - \frac{s\alpha \gamma^\frac{1}{4}}{2h^3} + O(\frac{1}{h^4}),
\]

(19)

for \( \lambda \).
Asymptotical expansion for energy

Asymptotical expansions (12) and (19) give us an expression for the energy term in the form of multipole expansion. In order to obtain this expansion one should insert

\[
E' = E_0 + \frac{E_1}{R} + \frac{E_2}{R^2} + \ldots
\]

into eqs.(12) and (19). Equating \(\lambda^{(n)}\) to be \(\lambda^{(\xi)}\) and taking into account (5), we get the following equations for coefficients \(E_1, E_2, \ldots\):

\[
E_1 = \frac{1}{6Z} \left[ (s\omega - 2k\omega^{-1})(2E_0)^{\frac{5}{2}} + (4s^2 - 16k^2 - 16\tau)(2E_0)^{\frac{3}{2}} \right],
\]

\[
E_2 = \frac{5}{2} E_1^2 + 2s\omega^{-1} E_0 + E_1(2E_0)^{\frac{1}{2}} Z^{-1}(16\tau^2 + 16k^2 - 4s^2),
\]

\[\ldots\ldots\ldots\]

Now we need to find \(E_0\). In order to find this value, we note that for \(R \to \infty\), \(E' = E_0\) and hence we have

\[
E = E_0 + \frac{\omega^2 R^2}{2} + \frac{4}{3} V_0.
\]  \hspace{1cm} (20)

On the other hand, for large \(R\) we have

\[
V(r_1, r_2) = \frac{2Z}{R} \sum_{l=0}^{\infty} \left( \frac{r}{R} \right)^l P_l(cos\theta) + \omega^2 \left[ (r^2 + 2r R cos\theta + \frac{R^2}{4}) + (r^2 - 2r R cos\theta + \frac{R^2}{4}) \right] \approx \omega^2 (2r^2 + \frac{R^2}{2}) - \frac{4}{3} V_0.
\]  \hspace{1cm} (21)

Hence, for the energy term with this potential we obtain

\[
E = 2\omega(N + \frac{3}{2}) + \frac{\omega^2 R^2}{2} + \frac{4}{3} V_0,
\]  \hspace{1cm} (22)

where \(N = n + q + m + 1\) is the principal quantum number. Comparing eqs.(20) and (22), we obtain

\[
E_0 = 2\omega(N + \frac{3}{2}).
\]
Thus, the following asymptotical expansion is obtained for the energy term of light quark in the field of two heavy quarks:

\[ E = -\frac{4}{3}V_0 + \frac{\omega^2 R^2}{2} + E_0 + \frac{E_1}{R} + \frac{E_2}{R^2} + \ldots \]

**QQq baryon spectra**

As mentioned above, the \( QQq \) binding energy can be finally obtained by solving the Schrödinger equation

\[
\left[-\frac{1}{2M_{QQ}}\Delta + V_{QQ}(R) + E(R)\right] \phi = \varepsilon \phi. \tag{23}
\]

If one takes \( E(R) \) in the form

\[ E = -\frac{4}{3}V_0 + \frac{\omega^2 R^2}{2} + E_0 + \frac{E_1}{R}, \]

for

\[ V_{QQ}(R) = \omega^2 R^2 - \frac{Z}{R} - \frac{2}{3} V_0, \]

then eq. (23) can be rewritten as

\[
\left[-\frac{1}{2M_{QQ}}\Delta + \omega^2 R^2 - \frac{Z'}{R} - V'_0 \right] \phi = \varepsilon \phi, \tag{24}
\]

where \( Z' = Z - E_1 \), \( \omega'^2 = \frac{3}{2} \omega^2 \) and \( V'_0 = 2V_0 - E_0 \).

To solve this equation, we use the result of [11] where a method for an analytical solution of the Schrödinger equation with potential

\[ V(R) = -\frac{Z}{R} + \lambda R^k \]

was offered. Details on this method and its application to our potential are given in Appendix. Application of this method to eq. (24) gives us

\[ \varepsilon_{Nnl} = 2\omega(N + \frac{3}{2}) + [Z'^2 \omega'^6 r_{nl}]^{1/5} - 2V_0, \tag{25} \]

where \( N \) is the principal quantum number of the light quark moving in the field of \( QQ \), \( r_{nl} \) is defined in Appendix. The formula (25) describes the
energy spectrum of the $QQq$ baryon. In tables 1, 2 and 3, the mass spectra of $ccq$, $bbq$ and $bcq$ baryons calculated using the formula (25) are given, respectively. The following values of potential parameters are chosen in this calculation $\alpha_s = 0.39$, $\omega^2 = 0.174 GeV^3$, $V_0 = 0.05 GeV$ for the potential

$$V = \frac{2}{3}(\frac{-\alpha_s}{r} + \omega^2 r - V_0).$$

**Conclusion**

In this work we have treated doubly heavy baryons in the Born-Oppenheimer approximation. The following two problems have been solved in the framework of this approximation: (1) the Schrödinger equation for two-center Coulomb plus harmonic oscillator potential and (2) the Schrödinger equation for central symmetric Coulomb plus harmonic oscillator potential. As the final result an analytical formula for the energy spectrum of baryons containing two heavy quarks is derived. Obtained formula is applied for the calculation of mass spectra of doubly heavy quark baryons with various quark compositions. The above analytical results could be useful for further numerical calculations in non-asymptotical region.

**Appendix**

1 **The scaling variational method and its application to Coulomb plus confining potential**

Consider the following Hamiltonian

$$H = -\frac{1}{2}\Delta + V(r),$$

which obeys the eigenvalue equation

$$H \psi_{nl} = E_{nl} \psi_{nl}, \quad <\psi_{nl} | \psi_{n'l'}> = \delta_{nn'}\delta_{ll'},$$

(27)
\( n, n' = 1, 2, \ldots, \quad l, l' = 1, 2, \ldots \)

where \( n \) and \( l \) denote the principal and angular quantum numbers, respectively. To solve this equation, we start from a set of functions \( \{\phi_{nl}\} \) which are the eigenfunctions of an arbitrary central field Hamiltonian \( H_0 \):

\[
H_0 \phi_{nl} = \epsilon_{nl} \phi_{nl}, \quad <\phi_{nl} | \phi_{n'l'}> = \delta_{nn'} \delta_{ll'}.
\] (28)

Then, we construct the functionals

\[
\epsilon_{nl}(\alpha) = <\phi_{nl}^\alpha | H \phi_{nl}^\alpha >,
\] (29)

where

\[
\phi_{nl}^\alpha = \alpha^{3/2} \phi_{nl}(\alpha r).
\]

The value for the \( \alpha \) is determined by

\[
\left( \frac{\partial \epsilon}{\partial \alpha} \right)(\alpha = a) = 0.
\] (30)

Let us now apply this method to our problem, i.e. to the Schrödinger equation with potential

\[
V(r) = -\frac{Z'}{R} + \omega^2 r^2.
\]

As \( H_0 \), we choose pure Coulomb Hamiltonian, i.e.

\[
H_0 = -\frac{1}{2} \Delta - \frac{Z'}{R}.
\]

Then, \( \epsilon_{nl} = -\frac{Z'^2}{2n^2} \) with \( n = n_r + l + 1 \), where \( n_r \) is the radial quantum number.

According to the above procedure, we have

\[
\epsilon_{nl}(\alpha) = <\phi_{nl}^\alpha | H_0 | \phi_{nl}^\alpha > + <\phi_{nl}^\alpha | \omega^2 r^2 | \phi_{nl}^\alpha > =
\]

\[
-\frac{Z'^2 \alpha^3}{2n^2} + \omega^2 \frac{\alpha^{-2}n^2}{2} [5n^2 + 1 - 3l(l + 1)],
\] (31)
For calculation of the second matrix element, we have used the well-known expression for average value $\bar{r}^2$ in Coulomb field which is given in [11].

From $\partial \varepsilon(\alpha)/\partial \alpha = 0$, we obtain

$$\alpha_0 = \left\{ -\frac{2\omega^2 n^4}{3 Z^2} [5n^2 + 1 - 3l(l + 1)] \right\}^{1/5}. $$

Then, for the energy level one can get the following analytical formula

$$\varepsilon_{nl} = [Z^2 \omega^6 r_{nl}]^{1/5}, \quad (32)$$

where

$$r_{nl} = n^2 [5n^2 + 1 - 3l(l + 1)]^3.$$
2 The formal procedure of the method of ethalon equation

Let’s consider the following second order differential equation:

\[ y''(x) + p^2[\lambda - q(x)]y(x) = 0 \] (33)

in the interval \([a, b]\). Let in this interval eq.(33) has one transition point (poles and zeros of function \(Q(x, \lambda) = q(x) - \lambda\) are called transition points of this equation).

Equation

\[ w''(z) - p^2 R(z) w(z) = 0 \] (34)

which has the same or close transition points as eq.(34) is called the ethalon equation for eq.(33).

Solution of eq.(33) we will seek in the form

\[ y(x) = [z'(x, p)]^{-1/2} w(z(x, p)) \] (35)

where \(w\) is the solution of eq.(34). Inserting (35) in to eq.(33) and taking into account eq.(34) we obtain the following (nonlinear) differential equation for \(z(x, p)\):

\[ R(z) z'^2 - Q(x, \lambda) - \frac{1}{2p^2} \{z, x\} = 0 \] (36)

here

\[ \{z, x\} = -\frac{3}{2} \left(\frac{z''}{z'}\right)^2 + \frac{z'''}{z'} \]

In the case of eq. (36) we have for \(Q\)

\[ Q = -\frac{h^2}{4} + \frac{h\lambda}{1 - \eta^2} - h^4 \gamma \eta^2 + \frac{1 - m^2}{(1 - \eta^2)^2} \]

and for \(R\) (from eq.8)

\[ R = -\left[ -\frac{h^4}{4} + \frac{h^4 k}{z} + \frac{1 - m^2}{4z^2} \right] \]
So, for $z$ one obtains eq. (10):

$$\frac{z''}{4} - \gamma(x-1)^2 - \frac{1}{h^2} \left( \frac{1}{4} + \frac{k'z''}{z} - \frac{\lambda}{2x(1-x/2)} \right) + \frac{\tau}{h^2} \left( \frac{1}{x^2(1-x^2)} - \frac{z''}{z^2} \right) - \frac{1}{2h^2} \{z, x\} = 0$$
Table 1. The mass spectrum of $ccq$ baryon (in GeV) calculated using the formula (25); $m_q = 0.385$ GeV, $m_c = 1.486$ GeV, $n_l$ and $n_d$ are the principal quantum numbers of light quark and $cc$ diquark, respectively, $L$ is the orbital quantum number of $cc$ diquark.

| $n_l, n_d, L$ | mass | $n_l, n_d, L$ | mass | $n_l, n_d, L$ | mass | $n_l, n_d, L$ | mass |
|---------------|------|---------------|------|---------------|------|---------------|------|
| 1,1,0         | 3.661| 1,1,1         | 3.613| 1,2,2         | 3.649| 1,3,3         | 3.694|
