Diversity and Functional Evolution of Terpene Synthases in Dictyostelid Social Amoebae

Xinlu Chen1, Tobias G. Köllner2, Gad Shaulsky3, Qidong Jia1, Jeroen S. Dickschat4, Jonathan Gershenzon2 & Feng Chen1

Dictyostelids, or social amoebae, have a unique life style in forming multicellular fruiting bodies from unicellular amoeboids upon starvation. Recently, dictyostelids were found to contain terpene synthase (TPS) genes, a gene type of secondary metabolism previously known to occur only in plants, fungi and bacteria. Here we report an evolutionary functional study of dictyostelid TPS genes. The number of TPS genes in six species of dictyostelids examined ranges from 1 to 19; and the model species Dictyostelium purpureum contains 12 genes. Using in vitro enzyme assays, the 12 TPS genes from D. purpureum were shown to encode functional enzymes with distinct product profiles. The expression of the 12 TPS genes in D. purpureum is developmentally regulated. During multicellular development, D. purpureum releases a mixture of volatile terpenes dominated by sesquiterpenes that are the in vitro products of a subset of the 12 TPS genes. The quality and quantity of the terpenes released from D. purpureum, however, bear little resemblance to those of D. discoideum, a closely related dictyostelid. Despite these variations, the conserved clade of dictyostelid TPSs, which have an evolutionary distance of more than 600 million years, has the same biochemical function, catalyzing the formation of a sesquiterpene protoillud-7-ene. Taken together, our results indicate that the dynamic evolution of dictyostelid TPS genes includes both purifying selection of an orthologous group and species-specific expansion with functional divergence. Consequently, the terpenes produced by these TPSs most likely have conserved as well as species-adaptive biological functions as chemical languages in dictyostelids.
aspect of the dictyostelids’ unique life style. Dictyostelium discoideum has been used as a model species for functional characterization of TPS genes. This species contains 9 TPS genes, all of which were shown to be expressed and active for the in vitro production of sesquiterpenes, while some of them also produce monoterpenes and diterpenes. Many of the identified in vitro terpene products were also released as volatile compounds from D. discoideum during multicellular development.

The dictyostelids are a monophyletic clade that can be subdivided into four taxonomic groups using molecular phylogeny. These four groups display enormous diversity in morphology and development. In our previous study, TPS genes were found in five species of dictyostelids and the number of TPS genes in these species ranges from 1 to 9. Such variation in the number of TPS genes poses intriguing questions: do paralogs in each species have similar or different catalytic functions? do paralogs and orthologs have similar or diverging expression patterns? how do the in vitro enzyme activities and gene expression patterns determine the chemical diversity of volatile terpenes produced by each dictyostelid species? what biological functions do these TPS genes and their terpene products have? Towards answering these questions, in this report, we investigate the functional evolution of the TPS family in dictyostelids using D. purpureum as the main model species.

Results and Discussion

Evolutionary relatedness of TPS genes from six species of dictyostelids. To conduct a comprehensive comparative analysis of the dictyostelid TPS gene family, six representative species were selected: D. fasciculatum, Actyostelium subglobosum, Polyphthoidium pallidum, D. lacteum, D. purpureum, and D. discoideum. There were two main justifications for this selection. First, these six species cover all major taxonomic groups for comparative genomics, comparative transcriptome analyses, and comparative biological studies of evolutionary distance of 400–300 million years.

In this study, 12 DpTPSs catalyzed the formation of complex sesquiterpene mixtures. The product spectra of DpTPS2 and DpTPS6 were dominated by the acyclic compound (E)-β-farnesene. DpTPS1 and DpTPS12 produced (E,E)-α-farnesene and α-selinene, respectively, as main products. The other enzymes formed mixtures of mainly unidentified sesquiterpene hydrocarbons or oxygenated sesquiterpenes.

Beside their sesquiterpene synthase activity, DpTPSs except DpTPS1 and DpTPS10 also exhibited monoterpen synthase activity when provided with geranyl diphosphate as substrate. While DpTPS3, DpTPS4, DpTPS6, DpTPS7, DpTPS8, DpTPS11, and DpTPS12 formed linalool as the major monoterpen product, DpTPS2 and DpTPS9 produced β-myrcene and DpTPS6 produced (Z)-β-ocimene as major product (Fig. S1). Seven DpTPSs accepted also geranylgeranyl diphosphate as substrate and catalyzed the formation of different unidentified diterpene alcohols (Fig. S2).

Catalytic activities of TPSs from D. purpureum. Prior to this study, D. discoideum was the only species of dictyostelids in which TPS genes have been functionally characterized. To gain insights into the functional evolution of dictyostelid TPSs through comparative analysis, in this study, D. purpureum was selected as a model species for TPS functional characterization. Both D. purpureum and D. discoideum belong to group 4 and are most closely related among the six species examined in this work (Fig. 1A), despite having a large evolutionary distance of 400–300 million years. D. purpureum and D. discoideum have been used as a pair of model species for comparative genomics, comparative transcriptome analyses and comparative biological studies of dictyostelids.

D. purpureum contains 12 TPS genes (designated DpTPS1-12), in contrast to 9 TPS genes in D. discoideum. Full-length cDNAs for all 12 TPS genes from D. purpureum were cloned and heterologously expressed in Escherichia coli. Because most DdTPSs function as sesquiterpene synthases, for comparison, individual recombinant DpTPSs were first tested with farnesyl diphosphate, the substrate for sesquiterpene synthases. All 12 DpTPSs were capable of producing sesquiterpene hydrocarbons or alcohols, indicating that the genes encode bona fide TPS enzymes (Fig. 2A). While DpTPS1 produced a sole compound, protoillul-7-ene, all the other 11 DpTPSs catalyzed the formation of complex sesquiterpene mixtures. The product spectra of DpTPS2 and DpTPS6 were dominated by the acyclic compound (E)-β-farnesene. DpTPS11 and DpTPS12 produced (E,E)-α-farnesene and α-selinene, respectively, as main products. The other enzymes formed mixtures of mainly unidentified sesquiterpene hydrocarbons or oxygenated sesquiterpenes.
Based on the phylogenetic analysis, *D. purpureum* DpTPS1, DpTPS2/9, and DpTPS4/5 were inferred to be orthologous to *D. discoideum* DdTPS6, DdTPS8, DdTPS5, and DdTPS3, respectively (Fig. 1B). The complete biochemical characterization of the DdTPS family (Fig. 2) and the DpTPS family enabled the functional comparison of these putative orthologs (Fig. S3). The first orthologous pair, DpTPS1 and DdTPS6, exhibited identical activities, producing a single sesquiterpene protoillud-7-ene, whereas the second orthologous pair, DpTPS6 and DdTPS8, exhibited distinct activities. The major product of DpTPS6 is (E)-β-farnesene, whereas the major product of DdTPS8 is an unidentified sesquiterpene. (E,E)-α-Farnesene is a common product of DpTPS7 and DdTPS8. The third putative pair of orthologs contains two genes from *D. purpureum* and six genes from *D. lacteum* were present in the grey group.
and DpTPS5 are completely different, the two major products of DpTPS5 (unidentified sesquiterpenes) have the same mass spectra as the two unidentified major products of DdTPS3.

Orthologous TPSs of clade I across the six dictyostelid species have the same catalytic activities. The orthologous pair of DpTPS1 and DdTPS6 belongs to clade I, and these enzymes have apparent orthologs in the other four species: DfTPS1 from *D. fasciculatum*, AsTPS1 from *A. subglobosum*, PpTPS18 from *P. pallidum* and DlTPS1 from *D. lacteum* (Fig. 1B). The observation that DpTPS1 and DdTPS6 have the same catalytic activity prompted us to ask whether the other orthologs have the same catalytic activities as well. To answer this question, the full-length cDNAs for DfTPS1, AsTPS1, PpTPS18 and DlTPS1 were cloned from the respective
Expression patterns of TPS genes during development of *D. purpureum* and comparative analysis. The multicellular development program in *D. purpureum* is initiated upon starvation. The 24-hour developmental process can be broadly divided into several stages: streaming, loose aggregate, mound, Mexican hat, and fruiting body (Fig. 1A). The expression of the DpTPS genes at seven time points during the 24 h development with 4 h intervals was extracted from a previous transcriptome analysis and presented in Fig. 3A.

All twelve TPS genes exhibited moderate levels of mRNA abundance and vast changes during the 24-hour course of the developmental process. Based on the mRNA abundance at the time of peak expression, the 12 genes can be categorized into three groups (Fig. 3A): high-abundance genes included DpTPS1, DpTPS8, DpTPS9 and DpTPS12, while medium-abundance genes were represented by DpTPS3, DpTPS5, DpTPS6 and DpTPS7, and low-abundance genes were DpTPS2, DpTPS4, DpTPS10 and DpTSP11. Furthermore, different time points for the highest expression levels of the DpTPS genes were observed. DpTPS2 was the only gene whose highest abundance levels occurred during vegetative growth (0 h). For all other genes, peak abundance occurred at various times during development. DpTPS1 and DpTPS7 were the two genes whose peak abundance happened at a time point during the first half of development. The highest expression of DpTPS9 and DpTPS12 occurred at the half point of development (12 h), while the peak abundance of the rest of the DpTPS genes was recorded during the second half of development (Fig. 3A).

The expression of orthologous pairs/groups between *D. purpureum* and *D. discoideum* was also compared (Fig. S4). It appeared that DpTPS9 and DdTPS5 had similar patterns of expression, and the same applied to DpTPS1 and DdTPS6. There were similarities between the expression patterns of DpTPS5 and DdTPS3, although the abundance of DdTPS5 was much higher.

During multicellular development, cells of *Dictyostelium* amoebae differentiate into two types: prestalk cells and prespore cells, which will eventually develop into the stalk and spores of the fruiting body. All 12 DpTPS genes in *D. purpureum* were enriched in prestalk cells (Fig. 3B). This pattern is different from that of DdTPS genes in *D. discoideum*. While the majority of DdTPS genes also showed preferential expression in prestalk cells, two of them, DdTPS1 and DdTPS8, have higher expression in prespore cells (Fig. 3C). This is an intriguing observation, but its significance cannot be evaluated until we understand the biological functions of the terpenes produced by these gene products.

Emission of volatile terpenes during development of *D. purpureum* and comparative analysis. Most DpTPS genes showed dynamic expression during multicellular development, suggesting that they may have a function during this process. In addition, all of the DpTPSs were active in producing sesquiterpenes and seven of them were active in producing monoterpenes in the in vitro enzyme assays (Fig. 2A). Since sesquiterpenes and monoterpenes are volatiles, we performed volatile profiling of *D. purpureum* culture during 24 h development. Volatile collections were performed in every four hours.

During this time course experiment a mixture of eight volatile sesquiterpenes was detected (Fig. 4), most of them were identified as the products of DpTPS1, DpTPS9 and DpTPS12. The predominant sesquiterpene was α-selinene, the major product of DpTPS12. Besides α-selinene, β-elemene, an unidentified sesquiterpene (peak31) and valencene were minor products produced by DpTPS12. From time point 4 to 24 hour, emission of these four sesquiterpenes produced by DpTPS12 increased with time, and reached the highest levels at 24 h. Protoilul-7-ene and germacrene D were produced by DpTPS1 and DpTPS9, respectively.

*D. discoideum* also released a mixture of volatile terpenes, including nine sesquiterpenes, one monoterpenone and one diterpene. In contrast to *D. purpureum* in which three DpTPS genes are main contributors of volatile production, the terpene products of all DdTTPs except DdTTP8 could be validated by the detection of DdTTP products in the volatile bouquet of *D. discoideum*. Among all the volatile terpenes emitted from the two species, only one terpene is common: protoilul-7-ene, which is the product of the ortholog pair DpTPS1 and DdTTP6 in the clade 1 (Fig. 1B). In *D. purpureum*, α-selinene is the most abundant terpene at any time throughout multicellular development. In contrast, in *D. discoideum* the most abundant terpene before 24 hours is different from that at 24 h during development.

Concluding Remarks

This study has led to new insights into the diversity and functional evolution of the TPS gene family in dictyostelid social amoebae. Through phylogenetic analysis, a conserved clade of TPS genes from the six species of social amoebae was identified (Fig. 1B), implying a common evolutionary origin of dictyostelid TPS genes. The variation in the number of TPS genes among the six species suggests group- or species-specific expansion of TPS genes through gene duplication. At the biochemical level, individual orthologs in this conserved clade encode enzymes of the same catalytic activity (Fig. 2B), while the paralogs in *D. purpureum* (Fig. 2A) as well as those in *D. discoideum* exhibit divergent catalytic functions. While essentially nothing is known about the biological function of terpenoids in dictyostelids, this family of metabolites is involved in diverse biological processes in other organisms. In plants, for example, some terpenoids function as phytohormones critical for regulating growth and development and many others are involved in mediating plant-environment interactions. In analogy, protoilul-7-ene, the product of DpTPS6 and its orthologs, may play a conserved, critical role, such as in regulating multicellular development, while the products of other TPS genes may have group- or species-adaptive functions, such as in chemotaxis, defense, or attracting beneficial organisms. Such functions have been
Figure 3. Expression of terpene synthase genes during dictyostelid development. (A) Expression of DpTPS genes during 24-hour development. Expression of DpTPS genes was measured by RPKM (reads per kilobase per million sequenced reads) based on RNA-Seq data produced from web-based interface program (http://dictyexpress.biolab.si/) and then displayed on a log2(RPKM + 1) scale in this line plot. The cartoons depict six stages of multicellular development: vegetative, individual cells (0h), streaming (8h), loose aggregate (10h), slug (16h), Mexican hat (20h), and fruiting bodies (24h). (B) Expression of D. purpureum TPS genes in prestalk and prespore cells. The numbers 1 to 12 correspond to DpTPS1 to DpTPS12. (C) Expression of DdTPS genes from D. discoideum in prestalk and prespore cells. The numbers 1 to 9 correspond to DdTPS1 to DdTPS9.
proposed for terpenoids as well as other types of secondary metabolites made by dictyostelid social amoebae. Knowledge of the catalytic activities of individual TPSs and their contribution to the biosynthesis of volatile terpenoids during multicellular development in *D. purpureum* and *D. discoideum* now enables future researchers to elucidate the specific role of individual TPS genes and their terpenoid products. For this endeavor, mutant strains with disrupted TPS genes that could be produced using restriction enzyme-mediated integration (REMI) mutagenesis or recently reported CRISPR/Cas9 technology for *Dictyostelium* will be particularly useful.

### Materials and Methods

#### Experimental organisms.

*D. purpureum* DpAX1 (DBS0308472), *Acytostelium subglobosum* LB1 (DBS0235452), *D. fasciculatum* SH3 (DBS0235810), *D. lacteum* (DBS0235831) and *Polysphondylium pallidum* PN500 (DBS0236808) were obtained from Dicty Stock Center (http://dictybase.org/). Five fruiting bodies of *D. purpureum* DpAX1 were added into 300 µl liquid culture of *Klebsiella pneumonia*, mixed well, and spread onto SM agar plate (http://dictybase.org/). Five fruiting bodies of *A. subglobosum* LB1, *D. fasciculatum* SH3, *D. lacteum* and *P. pallidum* PN500 were mixed with *E. coli* B/r stain, and spread onto LP agar plates (http://dictybase.org/). The plates were incubated at 22 °C in the dark.

#### Sequence and phylogenetic analysis.

Amino acid sequence dataset of *D. lacteum* (http://sacgb.leibniz-lli.de) was downloaded and searched against Pfam-A database locally using HMMER 3.0. Putative terpene synthase genes were identified using a HMM profile Terpene_synth_C (PF03936) with an e-value of 1e-2. Multiple sequences were aligned using MAFFT(L-INS-i). The maximum likelihood phylogenetic trees were built using RAxML under the LG + G + F model with 1000 bootstrap replicates.

#### Full-length cDNA cloning.

Social amoeba tissues at the stage of fruiting body were collected and homogenized using TissueLyser II according to manufacturer’s manual (https://www.qiagen.com). Total RNA was isolated using RNeasy Mini kit following manufacturer’s protocol (https://www.qiagen.com). cDNA was synthesized using First Strand Synthesis Kit according to manufacturer’s protocol (http://www.gelifesciences.com).

---

Figure 4. Volatile profiles of *Dictyostelium purpureum* culture during development. Volatile emissions during development of *D. purpureum* were collected by SPME and analyzed using GC-MS. All peaks labeled with a number are sesquiterpenes and the numbers correspond to the numbers of peaks in Figs 2 and 3. 1, protoillud-7-ene; 3, β-elemene; 28, germacrene D; 31, unidentified sesquiterpene hydrocarbon; 32, valencene; 33, α-selinene. Letters indicate compounds that are not found in the product spectra of DpTPS. "a", unidentified compound; "b", widdrol; "c", unidentified oxygenated sesquiterpene; "d", allo-hedycaryol; "e", unidentified oxygenated terpene. Compounds marked with asterisks (*) were identified using authentic standards. The cartoons depict six stages of multicellular development: vegetative, individual cells (0h), streaming (8h), loose aggregate (10h), slug (16h), Mexican hat (20h) and fruiting bodies (24h).
Full-length cDNA of individual TPS genes was amplified with gene specific primers (Table S2), cloned into vector pEXP5-CT/TOPO (https://www.thermofisher.com), and fully sequenced.

**Terpene synthase enzyme assays.** Individual social amoeba TPS genes in the pEXP5-CT/TOPO protein expression vector were transformed into *E. coli* BI21(DE3) for heterologous protein expression. Crude protein extracts were desalted into assay buffer (10 mM Tris-HCl, pH 7.5, 1 mM dithiothreitol, 10% (v/v) glycerol) before enzyme assays. The catalytic activity of each social amoeba TPS was determined in assays containing 50 μl of the crude protein and 50 μl of assay buffer with 10 μM substrate (geranyl dipiphosphate, farnesyl dipiphosphate or geranylgeranyl dipiphosphate). 10 mM MgCl₂ and 0.05 mM MnCl₂. A solid phase microextraction (SPME) fiber consisting of 100 μm polydimethylsiloxane (SUPELCO, Bellafonte, PA, USA) was inserted into the headspace of the assay vial. After incubation at 30 °C for 1 h, the SPME fiber was withdrawn from the vial and then inserted directly into the injector of the gas chromatograph. For the substrate geranylgeranyl dipiphosphate, assays were overlayed with 100 μl hexane. After extraction by vortexing, 2 μl of the organic phase was analyzed by GC/MS. A Hewlett-Packard model 6890 gas chromatograph coupled with a quadrupole mass selective detector was employed for product identification. Each assay was repeated at least three times and the results were found to be consistent.

**Expression analysis of terpene synthase genes in *D. purpureum* and *D. discoideum.** The expression data of individual TPS genes in *D. purpureum* and *D. discoideum* was obtained from the dataset reported previously and profiled using the dictyExpress web interface (https://dictyexpressresearch bcm.edu/landing/).

**Volatile profiling.** *D. purpureum* spores and freshly grown *K. pneumonia* were mixed and spread onto SM agar plates to initiate culture. Volatiles of *D. purpureum* cultures during 24-hour multicellular development were collected at seven time points (every 4 hours) using SPME and analyzed using GC-MS as previously reported.

**Data Availability**

Sequences of functionally characterized terpenes synthase genes from Dictyostelid social amoebae are available on GenBank: MG262459-MG262475.
