Monodromy of logarithmic Barsotti-Tate groups attached to 1-motives

July 2, 2003

Introduction

Let $R$ be a complete discrete valuation ring with perfect residue field $k$ of positive characteristic $p$ and field of fractions $K$. In this paper we consider a $K$-1-motive $M_K$ as in [14] and its associated Barsotti-Tate group. This last does not in general extend to a Barsotti-Tate group over $R$. However, with some assumptions, it extends to a logarithmic Barsotti-Tate group over $R$. This follows from [14] and Kato’s results on finite logarithmic group schemes. Once chosen a uniformizing parameter $\pi$ of $R$, any logarithmic Barsotti-Tate group over $R$ is described by two data $(G, N)$ where $G$ is a classical Barsotti-Tate group over $R$ and $N$ is a homomorphism of classical Barsotti-Tate groups. Moreover, if $R = W(k)$, $N$ induces a $W(k)$-homorphism $\mathcal{N}: \mathcal{M}(G_k) \to \mathcal{M}(G_k)$ on Dieudonné modules such that $F\mathcal{N}V = \mathcal{N}^2$ and $\mathcal{N}^2 = 0$. In the first part of the paper we recall these constructions and we show how to relate $N$ with the “geometric monodromy” introduced by Raynaud. In the second part of the paper we give an explicit description of $\mathcal{N}$ in terms of additive extensions and integrals. In the last part of the paper we describe how to recover the logarithmic Barsotti-Tate group attached to a 1-motive from a concrete scheme endowed with a suitable logarithmic structure.

1. 1-motives

Definition 1. Let $S$ be a scheme. An $S$-1-motive $M = [u: Y \to G]$ is a two term complex (in degree -1, 0) of commutative group schemes over $S$ such that:

- $Y$ is an $S$-group scheme that locally for the étale topology on $S$ is isomorphic to a constant group of type $\mathbb{Z}^r$,
- $G$ is an $S$-group scheme extension of an abelian scheme $A$ over $S$ by a torus $T$,
- $u$ is an $S$-homomorphism $Y \to G$.

Morphisms of $S$-1-motives are usual morphisms of complexes.
Definition 2. Let $M_K$ be a $K$-1-motive. One says that $M_K$

i) has good reduction if $M_K$ extends to a 1-motive over $R$, i.e. if

- $Y_K$ is not ramified over $R$,
- $T_K$ has good reduction over $R$,
- $A_K$ has good reduction over $R$,
- $u_K$ extends to a homomorphism $u: Y \to G$.

(Hence $G_K$ extends to a semi-abelian $R$-group scheme $G$.)

ii) has semistable reduction if

- $Y_K$ is not ramified over $R$,
- $T_K$ has good reduction over $R$,
- $A_K$ has semistable reduction over $R$.

(Hence $G_K$ extends to a smooth $R$-group scheme with semi-abelian special fibre.\(^1\))

iii) has potentially semistable (resp. good) reduction if it acquires semistable (resp. good) reduction after a finite extension of $K$.

iv) is strict if $G_K$ has potentially good reduction.

Observe that any $K$-1-motive has potentially semistable reduction. However, even if we allow base change, the morphism $u_K$ does not in general extend over $R$. A simple example is the Tate curve $u_K: \mathbb{Z} \to \mathbb{G}_{m,K}$ with $u_K(1) = \pi$ the uniformizing element. It has semistable reduction but no good reduction.

In the following we will consider only $K$-1-motives or $R$-1-motives. For more details see Raynaud’s paper [14].

1.1. The Barsotti-Tate group attached to a $K$-1-motive

Let $n$ be any positive integer and denote by $nH$ the kernel of $n$-multiplication on a group $H$. For any $K$-1-motive $M_K = [u_K: Y_K \to G_K]$ one can construct an exact sequence of finite $n$-torsion group schemes over $K$:

\[
\eta(n, u_K): 0 \to nG_K \to nM_K \to Y_K / nY_K \to 0
\]

where $nM_K$ is the cokernel of the homomorphism

\[
Y_K \xrightarrow{(-n, -u_K)} Y_K \times_{G_K} G_K;
\]

here the fibre product is taken with respect to $u_K$ on $Y_K$ and the $n$-multiplication on $G_K$. As explained in [14] 3.1, $nM_K$ is the $H^{-1}(C(M, n))$ with $C(M, n)$ the cone of the $n$-multiplication on the 1-motive $M_K$, i.e.

\[
C(M, n): Y_K \to Y_K \oplus G_K \to G_K
\]

\[
y \mapsto (-nx, -u_K(y)) = (y, g) \mapsto u_K(y) - ng
\]

in degree $-2, -1, 0$.

\(^1\) Cf. [14] §4.
**Definition 3.** The $p$-divisible group or Barsotti-Tate group of the $K$-1-motive $M_K$ is $\lim_{\to} (p^n M_K)$.

In the previous notations we have then an exact sequence of BT-groups:

$$0 \to \lim_{\to} (p^n G_K) \to \lim_{\to} (p^n M_K) \to \lim_{\to} (Y_K/p^n Y_K) \to 0.$$ 

It is clear that if $M_K$ has good reduction then $\lim_{\to} (p^n M_K)$ extends to a BT-group over $R$. We want to understand what happens in the general case. We state now a result that we will need later.

**Lemma 1.** Let notations be as above.

i) Consider the following diagram obtained via push-out by $u_K$:

$$
\begin{array}{c}
0 \\
0
\end{array} 
\begin{array}{c}
Y_K \\
G_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
Y_K/\!\!/nY_K \\
Y_K/\!\!/nY_K
\end{array} 
\begin{array}{c}
Y_K/\!\!/nY_K \\
G_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
0 \\
0
\end{array} 
\begin{array}{c}
G_K \\
Y_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
Y_K/\!\!/nY_K \\
Y_K/\!\!/nY_K
\end{array} 
\begin{array}{c}
G_K \\
0
\end{array}
$$

The short exact sequence $\eta(n, u_K)$ in (1) is isomorphic to the sequence of kernels for the $n$-multiplication of the lower sequence.

ii) Consider the following diagram obtained via pull-back by $u_K$:

$$
\begin{array}{c}
0 \\
0
\end{array} 
\begin{array}{c}
G_K \\
G_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
G_K \\
G_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
0 \\
0
\end{array} 
\begin{array}{c}
G_K \\
Y_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
G_K \\
Y_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
0 \\
0
\end{array} 
\begin{array}{c}
G_K \\
Y_K/\!\!/nY_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
G_K \\
Y_K/\!\!/nY_K
\end{array} 
\begin{array}{c}
\rightarrow \ 
\rightarrow
\end{array} 
\begin{array}{c}
0 \\
0
\end{array}
$$

The short exact sequence $\eta(n, u_K)$ in (1) is isomorphic to sequence of cokernels for the $n$-multiplication of the upper sequence.

Raynaud shows in [14] that to any $K$-1-motive it is possible to associate in a canonical way a $K$-1-motive with potentially good reduction $M_K'$ having the same BT-groups. His construction makes use of rigid analytic methods. As a consequence, working with BT-groups attached to a $K$-1-motive, one can always assume the $K$-1-motive to be strict. We will do so in the sequel.

1.2. Geometric monodromy

Given a strict $K$-1-motive, the failure of good reduction is controlled by a pairing, the so-called geometric monodromy. To define it we need to recall some facts on the Poincaré bundle.

**Remark 1.** Let $M_K = [u_K: Y_K \to G_K]$ be a $K$-1-motive with $Y_K$ be the group of characters of the torus part $T_K$ of $G_K$ and $A_K$ the abelian variety $G_K/T_K$. It is known\(^{2}\) that to give a 1-motive as above is equivalent to giving morphisms $h_K: Y_K \to A_K$, $h'_K: Y_K^* \to A_K^*$ (with $A_K^*$ the dual variety of $A_K$) and a trivialization $s_K: Y_K \times Y_K^* \to P_K$ of the pull-back via $h_K \times h'_K$ of

\(^{2}\) See for example [3] 10.2.14 and [1] II, 2.3.3.
the biextension \( \mathcal{P}_K \). Suppose that \( G_K \) has good reduction. Then both \( A_K \) and the dual abelian variety \( A_K^* \) have good reduction and the Poincaré bundle \( \mathcal{P}_K \) extends to a biextension \( \mathcal{P} \) in \( \text{Biext}^1(A, A^*; \mathbb{G}_{m,R}) \) on Néron models. Also \( h_K, h_K^* \) extend to morphisms \( h, h^* \) over \( R \) and the pull-back of \( \mathcal{P} \) via \( h \times h^* \) provides a biextension \( \mathcal{P}^Y \) in \( \text{Biext}^1(Y, Y^*; \mathbb{G}_{m,R}) \). Moreover this is trivial on generic fibres because of the existence of the trivialization \( s_K \).

**Definition 4** ([14] §4.3). Let \( M_K = [u_K : Y_K \to G_K] \) be a strict \( K \)-1-motive and \( Y_K^* \) the group of characters of \( T_K \). The geometric monodromy of \( M_K \) is a morphism

\[
\mu : Y_K \otimes Y_K^* \to \mathbb{Q}
\]

defined as follows:

i) Suppose that \( G_K \) has good reduction. Then \( \mathcal{P}^Y \in \text{Biext}^1(Y, Y^*; \mathbb{G}_{m,R}) \) is trivial on generic fibres (see remark 2). Hence the biextension \( \mathcal{P}^Y \) is the pull-back of

\[
0 \to \mathbb{G}_{m,R} \to \mathcal{G} \to i_*\mathbb{Z} \to 0
\]

via a unique \( \mu_0 \in \text{Hom}(Y_K \otimes Y_K^*, \mathbb{Z}) = \text{Hom}(Y \otimes Y^*, i_*\mathbb{Z}) = \text{Biext}^0(Y, Y^*; i_*\mathbb{Z}) \). One sets \( \mu = \mu_0 \).

ii) In the general situation, \( G_K \) reaches good reduction after a Galois extension \( K' \) of \( K \). Now the monodromy on \( K' \) is compatible with Galois action and can be descended to a \( \mu \) as in 4.

Observe that \( \mathbb{Q} \) has to be thought of as the group of values of the valuation of the algebraic closure of \( K \) with \( \mathbb{Z} \) the group of values assumed on \( K \).

Let \( K^{un} \) be the maximal unramified extension of \( K \), \( v : (K^{un})^* \to \mathbb{Z} \) the valuation and \( R^{un} \) its valuation ring. Observe that in the hypothesis of i) there is a valuation \( v_\mathcal{P} \) on \( \mathcal{P}_K(K^{un}) \) and that \( \mu_0 = v_\mathcal{P} \circ s_K \) holds. Moreover if the abelian part is trivial, then \( \mathcal{P}_K = \mathbb{G}_{m,K}, h_K \) and \( h_K^* \) are the structure morphisms and \( s_K : Y_K \otimes Y_K^* \to \mathbb{G}_{m,K} \) is the usual pairing \((y, y^*) \mapsto y^*(y) \). Hence \( \mu_0(y, y^*) = v(y^*(y)) \). These results can be generalized. See also 4.6/6 in [14].

**Lemma 2.** Let notations be as above. Suppose that \( G_K \) has good reduction over a finite field extension \( L \) of \( K \). Then the geometric monodromy pairing \( \mu \) coincides with the pairing

\[
Y_K \otimes Y_K^* \to \mathbb{Q}, \quad (y, y^*) \mapsto \frac{1}{e}v_L(y^*(t))
\]

where \( e \) is the index of ramification of \( L/K \), \( v_L \) is the extension of the valuation of \( L \) to \( L^{un} \), \( t \in T_K(L^{un}) \) is any point whose image in the component group \( \mathbb{Z}^d \) of \( T_{L^{un}} \) (as well as of \( G_{L^{un}} \)) coincides with the image of \( u_K(y) \) and \( y^*(t) \in (L^{un})^* \) for any \( y^* : T_{L^{un}} \to \mathbb{G}_{m,L^{un}} \).

**Proof.** We may reduce to the case \( L = K \). As explained above \( \mu_0(y, y^*) \) is obtained via the valuation on \( \mathcal{P}_K(K^{un}) \). Consider the push-out

\[
\begin{array}{cccccc}
0 & \to & T_K & \to & G_K & \to & A_K & \to & 0 \\
\downarrow y^* & & \downarrow s_{y^*} & & \downarrow & & \downarrow & \\
0 & \to & \mathbb{G}_{m,K} & \to & G_{y^*} & \to & A_K & \to & 0
\end{array}
\]

\( ^3 \) Notations are those in [6] VIII; we used that \( \text{Biext}^1(Y, Y^*; \mathcal{G}) \cong \text{Biext}^1(Y_K, Y_K^*; \mathbb{G}_{m,K}) \).
where $G_{\nu^*} \cong \mathcal{P}_{K[A_{\nu}]}$. The valuation $v_{\nu}$ on $\mathcal{P}_{K(K^{un})}$ restricts to a $v_{\nu^*}$ on $G_{\nu^*}(K^{un})$ and $\mu_0(\nu^*, y^*) = v_{\nu^*}(g_{\nu^*} \circ \nu_K(y))$ holds. Let now $t \in T_K(K^{un})$ be a point having the same image as $\nu_K(y)$ in the component group $\mathbb{Z}^d$. Then one has is $v_{\nu^*}(g_{\nu^*} \circ \nu_K(y)) = v(y^*(t))$ for any character $y^*$ and $\nu_K(y) - t \in G(R^{un})$. To conclude it is now sufficient to observe that $v_{\nu^*} \circ g_{\nu^*}$ is zero on $G(R^{un})$ and that $v(y^*(t)) = v_{\nu^*}(g_{\nu^*}t)$. \hfill \Box

1.3. Devisage

Once having realized that the defect of good reduction is controlled by the geometric monodromy, Raynaud explains, under the hypothesis that the geometric monodromy takes integer values, how to decompose a strict 1-motive into the sum of two 1-motives, the first having potentially good reduction and the second codifying the monodromy.

**Theorem 1.** Let $M_K = [u_K: Y_K \rightarrow G_K]$ be a strict $K$-1-motive such that the geometric monodromy $\mu$ factors through $\mathbb{Z}$. Then for any choice of a uniformizing parameter $\pi$ of $R$ there is a canonical decomposition

$$u_K = u_{K,\pi} + u_{K,\pi}^2$$

where $u_{K,\pi}^2$ factors through the torus part $T_K$ and is given by the formula

$$u_{K,\pi}^2: Y_K \rightarrow T_K = \text{Hom}(Y^*_K, G_m, K) \rightarrow G_K$$

$$y \mapsto (y^* \mapsto \pi^{v(y,y')})$$

while $u_{K,\pi}$ has potentially good reduction.

**Proof.** \cite{1}, 4.5.1 \hfill \Box

**Remark 2.** If both $G_K$ and $Y_K$ have good reduction, the geometric monodromy factors through $\mathbb{Z}$ and the 1-motive $u_{K,\pi}$ in the previous decomposition has good reduction.

**Remark 3.** Let notations be as above and $\rho: G_K \rightarrow A_K$ be the morphism of $G_K$ in its abelian quotient. It is clear that $\rho \circ u_K = \rho \circ u_{K,\pi}$ has potentially good reduction. Moreover the push-out of $\eta(n, u_K)$ with respect to $\rho_n: nA_K \rightarrow nA_K$ (the restriction of $\rho$ to the kernels of $n$-multiplication) is $\eta(n, \rho \circ u_K)$. More precisely we have:

$$\eta(n, u_K): \quad 0 \rightarrow nG_K \rightarrow nM_K \rightarrow Y_K/nY_K \rightarrow 0$$

$$\eta(n, \rho \circ u_K): \quad 0 \rightarrow nA_K \rightarrow nM_K^A \rightarrow Y_K/nY_K \rightarrow 0$$

Suppose that the hypothesis of Theorem \cite{1} holds. We wish to compare the sequence of finite $n$-torsion group schemes $\eta(n, u_K)$ in \cite{1} associated to $u_K$ with the sequences associated to $u_{K,\pi}^1$ and $u_{K,\pi}^2$. 
Lemma 3. Let $M_K: \left[ u_K : Y_K \to G_K \right]$ be a strict $K$-1-motive such that the geometric monodromy factors through $\mathbb{Z}$. Let $u_K = u_{K,\pi}^1 + u_{K,\pi}^2$ be the decomposition of Theorem \ref{thm:RaynaudDecomposition}. Then $\eta(n, u_K)$ is isomorphic to $\eta(n, u_{K,\pi}^1) + \eta(n, u_{K,\pi}^2)$ where + denotes Baer’s sum.

Proof. Consider the homomorphism

$$\text{Hom}(Y_K, G_K) \xrightarrow{\partial} \text{Ext}^1(Y_K, nG_K) \cong \text{Ext}^1_{\mathbb{Z}/n\mathbb{Z}}(Y_K/nY_K, nG_K)$$

that associates to a 1-motive $u_K$ the pull-back of $0 \to nG_K \to G_K \xrightarrow{n} G_K \to 0$ by $u_K$, resp. the sequence of cokernels of such pull-back. Here the subscript $\mathbb{Z}/n\mathbb{Z}$ stands for extensions in the category of $\mathbb{Z}/n\mathbb{Z}$-modules. We have already seen in Lemma \ref{lem:RaynaudDecomposition} ii) that the isomorphism class of $\eta(n, u_K)$ is $\partial(u_K)$. The result follows from the fact that $\partial$ is a homomorphism. \qed

Lemma 4. Given a $K$-1-motive $u_K: \mathbb{Z}^r \to \mathbb{G}_{m,K}^d$, (the isomorphism class of) the sequence $\eta(n, u_K)$ extends over $R$ if and only if $u_{K,\pi}^2$ is divisible by $n$, i.e. if and only if $\eta(n, u_{K,\pi}^2)$ is isomorphic to the trivial sequence.

Proof. Recall the following diagram

$$\begin{array}{ccc}
\text{Hom}(\mathbb{Z}^r, \mathbb{G}_{m,K}^d) & \xrightarrow{n} & \text{Hom}(\mathbb{Z}^r, \mathbb{G}_{m,K}^d) \\
\downarrow & & \downarrow \\
\text{Hom}(\mathbb{Z}^r, \mathbb{G}_{m,K}^d) & \xrightarrow{n} & \text{Hom}(\mathbb{Z}^r, \mathbb{G}_{m,K}^d) \\
\downarrow & & \downarrow \\
\mathbb{Z}^d & \to & \mathbb{Z}^d \\
\end{array}$$

where as above $\partial$ is obtained by pull-back. Suppose now that $\eta(n, u_K) = \partial(u_K)$ extends over $R$. The same is true for $\eta(n, u_{K,\pi}^1)$ because $u_{K,\pi}^1$ has good reduction and hence also $\eta(n, u_{K,\pi}^1)$ extends over $R$. Let $w_K$ be a 1-motive with good reduction such that $\eta(n, w_K) = \eta(n, u_{K,\pi}^2)$. Define $w'_K := w_K - u_{K,\pi}^2$, observe that this is also the Raynaud decomposition of $w'_K$ and that $\partial(w'_K) = 0$. Hence there exists a 1-motive $w''_K$ such that $n \cdot w''_K = w'_K$. Let $w''_{K,\pi} = w''_{K,\pi}^1 + w''_{K,\pi}^2$ be Raynaud’s decomposition. It is clear that the $n$-multiplication preserves Raynaud’s decompositions and hence $n \cdot w''_{K,\pi} = w_K$ while $n \cdot w''_{K,\pi}^2 = -u_{K,\pi}^2$. Hence $u_{K,\pi}^2$ is divisible by $n$. \qed

1.3.1. Geometric monodromy à la Kato. In the following we will work with group schemes as sheaves of $\mathbb{Z}$-modules on the flat site. We wish to understand better the $K$-1-motive $u_{K,\pi}^2$ in order to compare Kato’s monodromy and Raynaud’s monodromy.

Given an étale group scheme $N_K$ isomorphic to $\mathbb{Z}^r$ over an algebraic closure of $K$, denote by $N_K^\vee$ the étale group scheme $\text{Hom}(N_K, \mathbb{Z})$ and by $N_K^{\vee,D}$ its Cartier dual. We have $\mathbb{Z}^{\vee,D} = \mathbb{G}_{m,K}$ and $N_K^{\vee,D} = N_K \otimes_{\mathbb{Z}} \mathbb{G}_{m,K}$. The geometric monodromy $\mu: Y_K \otimes_{\mathbb{Z}} Y_K^* \to \mathbb{Z}$ of $u_K$, provides a morphism

$$\begin{align}
\nu: Y_K & \to \text{Hom}(Y_K^*, \mathbb{Z}) =: (Y_K^*)^\vee \\
y & \mapsto \mu(y, -)
\end{align}$$

(7)
and hence a morphism of tori

\[ \nu \otimes \text{id} : Y_K \otimes \mathbb{G}_{m,K} \to (Y_K^*)^\vee \otimes \mathbb{Z} \mathbb{G}_{m,K} = (Y_K)^D = T_K. \]

Let \( H_K(1) \) denote the Cartier dual of the Pontrjagin dual for any finite \( \text{étale} \) \( K \)-group scheme \( H_K \). Then \( \mu_n = \mathbb{Z}/n\mathbb{Z}(1) \) and if \( n \) kills \( H_K \) one has \( H_K(1) = H_K \otimes \mathbb{Z}/n\mathbb{Z} \mu_n \). Hence we can introduce a “monodromy” homomorphism of level \( n \)

\[ \nu_n : Y_K/nY_K(1) = Y_K \otimes \mathbb{Z} \mu_n \to (Y_K^*)^\vee \otimes \mathbb{Z} \mu_n = nT_K \quad (\to nG_K) \]

as the restriction of \( \nu \otimes \text{id} \) to the \( n \)-torsion subgroups. It was defined in \([14] 4.6\).

Consider now the Tate 1-motive

\[ \pi : \mathbb{Z} \to \mathbb{G}_{m,K}, \ 1 \mapsto \pi. \]

It is clear from \((5)\) that \( u^2_{K,\pi} \) has the following factorization

\[ u^2_{K,\pi} : Y_K \otimes \mathbb{G}_{m,K} \to (Y_K^*)^\vee \otimes \mathbb{Z} \mathbb{G}_{m,K} = (Y_K)^D = T_K. \]

where \( \nu \) was defined in \((6)\).

**Lemma 5.** Let \( G_K \) have good reduction \( G \), \( \iota : T_K \to G_K \) be the torus part and suppose that \( Y_K \) extends to an \( \text{étale} \) group \( Y \) over \( R \). Then the homomorphism

\[ \text{Hom}(Y,G) \times \text{Hom}(Y_K \otimes \mathbb{G}_{m,K}, T_K) \to \text{Hom}(Y_K, G_K) \]

\[ (u^1, w_K) \mapsto u^1_K + \iota \circ w_K \circ \pi_Y \]

is an isomorphism.

The homomorphism \( \pi_Y \) was defined in \((10)\).

**Proof.** The surjectivity is clear because any homomorphism \( u_K \) on the right hand side represents a \( K \)-1-motive and we have just seen how to decompose \( u_K \) as sum of a 1-motive \( u^1_{K,\pi} \) and a 1-motive \( u^2_{K,\pi} = \iota \circ (\nu \otimes \text{id}) \circ \pi_Y \). Hence \( u_K \) is the image of the pair \((u^1, \nu \otimes \text{id})\). For the injectivity: the first group on the left injects into \( \text{Hom}(Y_K, G_K) \), so we are reduced to showing that given a \( w_K \in \text{Hom}(Y_K \otimes \mathbb{G}_{m,K}, T_K) \) the \( K \)-1-motive \( \iota \circ w_K \circ \pi_Y \) has good reduction if and only if \( w_K \) is trivial. Denote by \( \mu(w_K) \) the pairing corresponding to \( w_K \) via the canonical isomorphisms

\[ \text{Hom}(Y_K \otimes \mathbb{G}_{m,K}, T_K) = \text{Hom}(Y_K^*, Y_K^*) = \text{Hom}(Y_K \otimes Y_K^*, \mathbb{Z}). \]

The image of \((0, w_K)\) via the map in \((11)\) is a \( K \)-1-motive; let \( \mu(w_K) \) denote its geometric monodromy. Such \( K \)-1-motive has good reduction if and only if \( \mu(w_K) = 0 \) and this last occurs if and only if \( w_K = 0 \). \( \square \)

We restrict again to the consideration of the 1-motive \( \pi : \mathbb{Z} \to \mathbb{G}_{m,K}, \ 1 \mapsto \pi. \) Observe that it satisfies the hypothesis of remark \( [2] \) and that in this case \( u^1_{K,\pi} \) is trivial. Let denote by

\[ \theta^\pi_{n,K} : 0 \to \mu_n \to nE_K \to \mathbb{Z}/n\mathbb{Z} \to 0 \]

the short exact sequence \( \eta(n, \pi) \). The following results will be used in Theorem \( [3] \) to compare Raynaud’s monodromy and Kato’s monodromy.

---

\(^4\) The Pontrjagin dual of \( H_K \) is \( \text{Hom}(H_K, \mathbb{Q}/\mathbb{Z}). \)
Theorem 2. Let \( n \) be a positive integer and \( \theta^{\pi}_{n,K} \) the short exact sequence just defined. Suppose that \( u_K \) is a strict \( K \)-1-motive as in Theorem 1 with \( u_K = u^{1}_{K,\pi} + u^{2}_{K,\pi} \) its Raynaud decomposition.

i) The geometric monodromy of \( u_K \) and the one of \( u^{2}_{K,\pi} \) coincide.

ii) The short exact sequence \( \eta(n, u^{2}_{K,\pi}) \) associated to \( M^{2}_{K} = [u^{2}_{K,\pi} : Y_K \rightarrow T_K] \) is isomorphic to the push-out via \( \nu_n \) of the sequence

\[
\theta^{\pi}_{n,K} \otimes \mathbb{Z}/n\mathbb{Z} Y_K/nY_K : \quad 0 \rightarrow \mu_n \otimes \mathbb{Z}/n\mathbb{Z} Y_K/nY_K \rightarrow \eta_n \otimes \mathbb{Z}/n\mathbb{Z} Y_K/nY_K \rightarrow Y_K/nY_K \rightarrow 0
\]

Proof. The first fact follows immediately from the definition of \( u^{2}_{K,\pi} \). For the second assertion, consider the factorization of \( u^{2}_{K,\pi} \) described in (10). It says that there is a commutative diagram

\[
\begin{array}{c}
\eta(n, \pi_Y) : & 0 & \rightarrow & n(Y^{\pi}_{K})^D & \rightarrow & nM^{2}_{K} & \rightarrow & Y_K/nY_K & \rightarrow & 0 \\
& \downarrow & & \nu_n & & \downarrow & & \downarrow & & \downarrow \\
\eta(n, u^{2}_{K,\pi}) : & 0 & \rightarrow & nT_K & \rightarrow & nM^{2}_{K} & \rightarrow & Y_K/nY_K & \rightarrow & 0
\end{array}
\]

where \( M^{2}_{K} = [\pi_Y : Y_K \rightarrow Y_K \otimes \mathbb{Z}_{m,K}] \). It is clear that \( \eta(n, \pi_Y) = \theta^{\pi}_{n,K} \otimes Y_K/nY_K \) by definition of \( \pi_Y \). Hence \( \eta(n, u^{2}_{K,\pi}) \) is isomorphic to \( \nu_n(\theta^{\pi}_{n,K} \otimes Y_K/nY_K) \), i.e. to the push-out via \( \nu_n \) of the sequence \( \theta^{\pi}_{n,K} \otimes \mathbb{Z}/n\mathbb{Z} Y_K/nY_K \). \( \square \)

Corollary 1. Suppose furthermore that \( Y_K \) and \( G_K \) have good reduction and consider the following homomorphism

\[
\Psi : \text{Ext}^{1}_{\mathbb{Z}/n\mathbb{Z}}(Y^{\pi}_{nY_{K}}(1), nG_{K}) \rightarrow \text{Ext}^{1}_{\mathbb{Z}/n\mathbb{Z}}(Y^{\pi}_{nY_{K}}(1), nG_{K})
\]

(13)

\[
\begin{array}{c}
(\eta^{1}, h) & \rightarrow & \eta^{1}_{K} + h_{\ast}(\theta^{\pi}_{n,K} \otimes \mathbb{Z}/n\mathbb{Z} Y^{\pi}_{nY_{K}})
\end{array}
\]

where \( \eta^{1}_{K} \) means the restriction of \( \eta^{1} \) to generic fibres.

i) If \( u_K : Y_K \rightarrow G_K \) is a \( K \)-1-motive with Raynaud decomposition \( u_K = u^{1}_{K,\pi} + u^{2}_{K,\pi} \), then the class of \( \eta(n, u_K) \) lies in the image of \( \Psi \). More precisely it corresponds to the pair \( (\eta(n, u^{1}_{K,\pi}), \nu_n) \) where \( \nu_n \) is the “monodromy” homomorphism of level \( n \) as in (10) and \( u^{1}_{K,\pi} \) is the \( R \)-1-motive that extends \( u^{1}_{K,\pi} \).

ii) If \( Y_K \cong \mathbb{Z}^{r} \) and \( G_K \cong \mathbb{G}^{d}_{m,K} \), then \( \Psi \) is an isomorphism.

Proof. The first assertion is an immediate consequence of the previous Theorem, part i). We restrict then to the case \( nG_K = \mu^{d}_{K} \) and \( Y_K/nY_K = \mathbb{Z}^{r}/n\mathbb{Z}^{r} \). For the surjectivity it is sufficient to remark that any extension class on the right is represented by a \( \eta(n, u_K) \) for a strict \( K \)-1-motive \( u_K \) because of the vanishing of \( H^{1}(K, \mathbb{G}^{d}_{m,K}) = \text{Ext}^{1}(\mathbb{Z}, \mathbb{G}^{d}_{m,K}) \). For the injectivity: the group of extensions on the left injects in the group of extensions on the right. It remains to check that \( h_{\ast}(\theta^{\pi}_{n,K} \otimes \mathbb{Z}^{r}/n\mathbb{Z}^{r}) \) extends over \( R \) if and only if \( h = 0 \). Now, \( h : \mu^{d}_{K} \rightarrow \mu^{d}_{K} \) extends to many homomorphisms \( \hat{h} : \mathbb{G}^{d}_{m,K} \rightarrow \mathbb{G}^{d}_{m,K} \). Choose one of them and let \( u_K : \mathbb{Z}^{r} \rightarrow \mathbb{G}^{d}_{m,K} \) be \( \hat{h} \circ \pi_{\mathbb{Z}^{r}} \) with \( \pi_{\mathbb{Z}^{r}} \) as in (10). It is clear that \( h \) coincides with the monodromy homomorphism of level \( n \) of the \( K \)-1-motive \( u_K \). By hypothesis \( \eta(n, u_K) \cong h_{\ast}(\theta^{\pi}_{n,K} \otimes \mathbb{Z}^{r}/n\mathbb{Z}^{r}) \) extends over
R. Hence $u_K = u_{K,1}^1 + u_{K,1}^2$ with $u_{K,1}^2$ divisible by $n$ (see Lemma 4). This implies that the monodromy of $u_K$ that equals the monodromy of $u_{K,1}^2$ is a multiple of $n$ and hence its monodromy homomorphism of level $n$ is trivial, i.e. $h = 0$. □

Theorem 2 ii) and its corollary are the only original results of the first part of this paper. They become interesting once one realizes that Kato proves an analogous result for extensions of finite logarithmic group schemes (cf. Theorem 3). The comparison of these two results makes it possible to extend $nM_K$ to a finite logarithmic group scheme over $R$.

We close this section by giving an example that should clarify all the previous constructions.

1.3.2. Tate’s curve. Let $n$ be a positive integer and

$$u_K: \mathbb{Z} \to \mathbb{G}_m,K; \ 1 \mapsto \epsilon \pi^{nr+s}, \ 0 \leq s \leq n - 1, \ 0 \leq r, \ \epsilon \in R^*$$

an elliptic curve with split multiplicative reduction. The canonical decomposition of Theorem 1 provides $u_{K,1}^2: \mathbb{Z} \to \mathbb{G}_m,K, 1 \mapsto \pi^{nr+s}$ and $u_{K,1}^1: \mathbb{Z} \to \mathbb{G}_m,K, 1 \mapsto \epsilon$. The geometric monodromy $\mu: \mathbb{Z} \to \mathbb{Z}$ depends only on $u_{K,1}^2$ and it sends $1 \mapsto rn + s$. The “monodromy” homomorphism of level $n$, $\nu_n: \mathbb{Z}/n\mathbb{Z} \to \mu_n = \mu_n \mapsto \mu_n$, is the $s$-multiplication. It is also clear that $\eta(n, u_{K,1}^2)$ is isomorphic to $s \cdot \theta_{n,K}^\pi$.

2. Finite logarithmic group objects

For the theory of logarithmic spaces we refer to [11] and [9]. We need also some definitions and results in [7], [8].

Let $\pi$ be a fixed uniformizing element of $R$ and $T$ the spectrum of $R$ with the standard log structure given by the chart $N \to R$, $1 \mapsto \pi$. Denote by $T_{\text{fl}}^{\log}$ the logarithmic flat site over $T$. A finite (representable) logarithmic group $G$ over $R$ is a sheaf of abelian groups over $T_{\text{fl}}^{\log}$ that is represented by a fine saturated log-scheme over $R$, log flat and of Kummer type over $R$ so that its underlying scheme is finite over $R$. For an example, consider Tate’s elliptic curve $E_K$ defined via $\pi: \mathbb{Z} \to \mathbb{G}_m,K, 1 \mapsto \pi$. Kato shows how to extend $E_K$ to a group object $E_\pi$ in the category of valuative logarithmic spaces over $R$. This is explained by Illusie in [11] 3.1. The kernel of $n$-multiplication on $E_\pi$, denoted by $n(E_\pi)$, is obtained via log blow-ups from a logarithmic space having

$$(14) \quad nE = \text{Spec} \left( \bigoplus_{i=0}^{n-1} \frac{R[x]}{(x^n - \pi)} \right)$$

as underlying scheme. Moreover there is a short exact sequence of finite logarithmic groups given by

$$(15) \quad \theta_n^\pi: 0 \to \mathbb{Z}/n\mathbb{Z}(1) \to n(E_\pi) \to \mathbb{Z}/n\mathbb{Z} \to 0$$

(cf. [11] 3.2.1.4) whose restriction to generic fibres is the short exact sequence $\theta_{n,K}^\pi$ that we used in Theorem 2 (cf. [11] 3.2.1.4.).

Let now $F$ (resp. $H$) be $n$-torsion finite (resp. finite étale) group schemes over $R$ endowed with the inverse image log structure. A result of Kato (cf. [7] p. 84) says that extensions (of sheaves in $T_{\text{fl}}^{\log}$)

$$\eta^{\text{log}}: 0 \to F \to G^{\log} \to H \to 0$$
correspond bijectively (up to isomorphisms) to pairs \((G^{cl}, N)\) where
\[
\eta^{cl}: \quad 0 \to F \to G^{cl} \to H \to 0
\]
is a classical extension of group schemes over \(R\) and \(N: H(1) \to F\) is a morphism of \(R\)-group schemes where \(H(1) = H \otimes_{\mathbb{Z}/n\mathbb{Z}} \mu_n\). Moreover \(\eta^{log}\) is the Baer sum of \(\eta^{cl}\) and the push-out by \(N\) of the extension \(\theta_n^{\pi} \otimes_{\mathbb{Z}/n\mathbb{Z}} H\).

**Theorem 3 (Kato).** Let notations be as above. There is an isomorphism
\[
\Ext^1_{\mathbb{R}^0}(H, F) \times \Hom(H(1), F) \xrightarrow{\sim} \Ext_{T^{log}}(H, F)
\]
\[
(\eta^{cl}, N) \quad \mapsto \quad \eta^{cl} + N_{*}(\theta_n^{\pi} \otimes H)
\]

*Proof.* cf. \[7\]. □

Observe that the statement of this theorem is similar to that of Corollary \[1\]. We will explain in Theorem 4 that they are deeply related. Before proceeding we need the following result.

**Lemma 6.** Let \(M_K = [u_K: Y_K \to G_K]\) be a \(K\)-1-motive and suppose that \(G_K\) extends to a semiabelian \(R\)-scheme \(G^s\) while \(Y_K\) extends to an étale \(R\)-group scheme \(Y^s\). Taking fixed a uniformizing parameter \(\pi\) of \(R\), let \(u_K = u_K^{1,\pi} + u_K^{2,\pi}\) be Raynaud’s decomposition of Theorem \[7\]. Then:

i) \(u_K^{1,\pi}\) extends to a \(R\)-1-motive \(u_{n,\pi}^{1}\);

ii) The monodromy homomorphism of level \(n\) of \(u_K\), i.e. \(\nu_n: Y_K/nY_K(1) \to nG_K\), extends to a homomorphism \(\nu_{n,R}: Y/nY(1) \to nG\).

*Proof.* Both assertions are evident because it follows from the hypothesis that the torus part \(T_K\) of \(G_K\) extends to a torus over \(R\); hence also its group of characters \(Y^*_K\) extends to an étale group over \(R\), say \(Y^*\). This implies that the geometric monodromy takes values in \(\mathbb{Z}\) and it extends to a biadditive map \(Y \otimes Y^* \to \mathbb{Z}\) over \(R\). This last provides the homomorphism \(\nu_{n,R}\) we are looking for. □

We can now state the relation between Raynaud’s geometric monodromy of a \(K\)-1-motive and Kato’s monodromy of its logarithmic BT-group.

**Theorem 4.** Let \(M_K = [u_K: Y_K \to G_K]\) be a \(K\)-1-motive and suppose that \(G_K\) extends to a semiabelian \(R\)-scheme \(G^s\) while \(Y_K\) extends to an étale \(R\)-group scheme \(Y^s\). Let \(\nu_{n,R}\) be the homomorphism in Lemma \[8\] with \(u_{n,\pi}^{1}: Y \to G\) the \(R\)-1-motive that extends the \(u_{K,\pi}^{1}\) of Raynaud’s decomposition.

The sequence \(\eta(n, u_K)\) in \[4\] extends (up to isomorphisms) to a sequence of finite logarithmic group schemes and precisely, in the notations of Theorem \[9\] to the one associated to \((\eta(n, u_{K,\pi}^{1}), \nu_{n,R})\).

In particular, \(\nu_n\) (i.e. Raynaud’s monodromy homomorphism of level \(n\) associated to \(u_K\)) is Kato’s monodromy homomorphism \(N\) restricted to generic fibres.

*Proof.* We know from Lemma \[8\] and Theorem \[2\] that \(\eta(n, u_K)\) is isomorphic to
\[
\eta(n, u_{K,\pi}^{1}) + (\nu_n)_{*}(\theta_n^{\pi} \otimes Y_K/nY_K).
\]
Moreover, as \( u_{K,\pi} \) extends to an \( R \)-1-motive \( U^1_\pi \) (cf. Lemma \([6]\)) also \( \eta(n, u_{K,\pi}^1) \) extends to a sequence of classical group schemes \( \eta(n, u_{K,\pi}^1) \); on the other hand the sequence \( \theta_n^\pi \) in \([12]\) extends to the sequence of logarithmic groups that we denoted by \( \theta_n^\pi \) in \([15]\). Hence the sequence of logarithmic groups \( \eta(n, u_{K,\pi}^1) + (\nu_{n,R})_*(\theta_n^\pi \otimes Y/nY) \) restricted to generic fibres is (up to isomorphisms) \( \eta(n, u_{K,\pi}) \). \( \square \)

As all constructions above behave well with respect to inclusion homomorphisms \( p^m M_K \to p^{m+1} M_K \) we can conclude that:

**Corollary 2.** With hypothesis as above, let \( M^1 \) denote the \( R \)-1-motive \([u^1_K : Y \to G]\). The \( BT \)-group of \( u_K, \lim(p^m M_K) \), extends to a logarithmic \( BT \)-group \( \lim(p^m M^1, \nu_{p^m,R}) \) where \( \lim p^m M^1 \) is the \( BT \)-group of \( M^1 \).

**Remark 4.** Let \( F = (\mathbb{Z}/n\mathbb{Z})^r \) and \( H = \mu_n^d \). The decomposition in Theorem \([3]\) restricted to generic fibres coincides with the isomorphism of Corollary \([1]\) in particular this is true working with the \( K \)-1-motive \( E_K = [u_K : \mathbb{Z} \to \mathbb{G}_{m,K}] \) given by \( 1 \mapsto q = \pi^n s^r + s, 0 \leq s \leq n - 1, \epsilon \in R^* \). The kernel of \( n \)-multiplication \( _n E_K \) extends (up to isomorphism) to a finite logarithmic group \((E^\text{cl}, N)\) where \( N \) is the \( s \)-multiplication on \( \mu_n \) and \( n E^\text{cl} \) is the finite group scheme that lies in the middle of \( \eta(n, u_{K,\pi}^1) \) for \( u_{K,\pi}^1 : \mathbb{Z} \to \mathbb{G}_{m,R}, 1 \mapsto \epsilon. \)

## 3. Monodromy on Dieudonné modules

Throughout this section \( R = W(k) \) and \( M_K = [u_K : Y_K \to G_K] \) will be a fixed \( K \)-1-motive with \( Y_K \cong \mathbb{Z}^r \). We will suppose that \( G_K \) has good reduction and its extension over \( R \), \( G \), has split torus part of rank \( d > 0 \). We have seen in Corollary \([2]\) that under these hypotheses the \( BT \)-group \( M_K(p) := \lim(p^m M_K) \) associated to \( u_K \) extends to a logarithmic \( BT \)-group, say \( M(p)^\log = (M(p), N) \) where \( M(p) = \lim(p^m M^1_p) \) is a classical \( BT \)-group over \( R \) and 

\[
M(p)^\log \twoheadrightarrow M(p) \twoheadrightarrow (M(p), N) \twoheadrightarrow \lim(p^m G) \rightarrow 0
\]

is the monodromy homomorphism: the first morphism is \( \nu_R \otimes \text{id} \) where \( \nu_R \) is the extension of \( \nu : Y_K \to Y_K^{\text{cl}} \) in \([7]\) over \( R \), which exists since \( Y_K, Y_K^{\text{cl}} \) are unramified.

### 3.1. The identification of Dieudonné modules of \( \mathbb{Q}_p/\mathbb{Z}_p \) and \( \mu_p \)

For the theory of Dieudonné modules we refer to \([4]\). If \( G \) is a \( BT \)-group over \( k \), its Dieudonné module is \( \mathbb{D}(G) = \text{Hom}(G, \mathbb{C}W_k) \), where Hom means homomorphisms of \( k \)-formal groups. In particular, \( \mathbb{D}(\mathbb{Q}_p/\mathbb{Z}_p)_k = \zeta W(k) \) is a free \( W(k) \)-module of rank 1 whose canonical generator \( \zeta \) is the natural embedding of \( (\mathbb{Q}_p/\mathbb{Z}_p)_k \) in \( \mathbb{C}W_k \) once \( \mathbb{Q}_p/\mathbb{Z}_p \) is identified with \( CW(\mathbb{F}_p) \); more precisely, \( \zeta \) corresponds to the covector \( y = (\ldots, y_{-2}, y_{-1}) \in \mathbb{C}W_k(k^{\mathbb{Q}_p/\mathbb{Z}_p}) \) defined by \( y_{-i} = \sum_{a \in \mathbb{Q}_p/\mathbb{Z}_p} a_{-i} f_a \), where \( f_a(b) = \delta_{ab} \) is the Kronecker delta.

Let us recall that elements of \( \mathbb{D}(G) \) can also be described as isomorphism classes of rigidified extensions of \( G \) by \( \mathbb{G}_{a,*} \) (as fppf sheaves, cf. \([10]\) §5.2 or \([12]\) §15). Given a \( \varphi \in \mathbb{D}(G) \), the corresponding additive extension is obtained as the pull-back via \( \varphi \) of the extension 

\[
0 \to \mathbb{G}_{a,*} \to \mathbb{C}W_k \xrightarrow{\varphi} \mathbb{C}W_k \to 0
\]
where $V$ is the Verschiebung of $CW_k$; it will be denoted by $\varphi_{p^\infty}^{\text{add}}$. In particular, one can prove that the extension
\[ \zeta_{p^\infty}^{\text{add}} : 0 \to \mathbb{G}_{a,k} \to F \to (\mathbb{Q}_p/\mathbb{Z}_p)_k \to 0, \]
is isomorphic to the push-out of
\[ (16) \quad \zeta_{p^\infty} : 0 \to \mathbb{Z} \to \mathbb{Z}[1/p] \xrightarrow{\ell} \mathbb{Q}_p/\mathbb{Z}_p \to 0 \]
via the canonical homorphism $\mathbb{Z} \to \mathbb{G}_{a,k}$. Let $\sigma : \mathbb{Q}_p/\mathbb{Z}_p \to \mathbb{Z}[1/p]$ be the section of $f$ such that $0 \leq \sigma(a) < 1$, for $a \in \mathbb{Q}_p/\mathbb{Z}_p$. The factor set of $\zeta_{p^\infty}$ (and hence of $\zeta_{p^\infty}^{\text{add}}$) corresponding to the section $\sigma$ is then
\[ (17) \quad \gamma : (\mathbb{Q}_p/\mathbb{Z}_p) \times (\mathbb{Q}_p/\mathbb{Z}_p) \to \mathbb{Z} \to \mathbb{G}_{a,k}, \quad (a, b) \mapsto [\sigma(a) + \sigma(b)] \]
where square brackets mean integral part. The extension $\zeta_{p^\infty}^{\text{add}}$ has a canonical lifting $(\zeta_{p^\infty}^{\text{add}})^R$ to $R$ obtained as the push-out of $\zeta_{p^\infty}$ in \( \mathbb{Q}_p/\mathbb{Z}_p \) (now as a sequence over $R$) via the morphism $\mathbb{Z} \to \mathbb{G}_{a,R}$. The restriction of $(\zeta_{p^\infty}^{\text{add}})^R$ on generic fibres splits, and the map
\[ h : \lim_{\to} \mathbb{Z}/p^i \mathbb{Z} = \mathbb{Q}_p/\mathbb{Z}_p \to \mathbb{G}_{a,K}, \quad a \mapsto \sigma(a) \]
is the trivialisation. Let $K[X]$ be the affine algebra of $\mathbb{G}_{a,K}$ and let $h^* : K[X] \to K^{\mathbb{Z}/p^i \mathbb{Z}}$, $i > 0$, be the corresponding $K$-homomorphisms; one gains an element
\[ (18) \quad h^*(X) = \sum_{a \in \mathbb{Q}_p/\mathbb{Z}_p} \sigma(a)f_a \in K^{\mathbb{Q}_p/\mathbb{Z}_p} = \lim_{\leftarrow} K^{\mathbb{Z}/p^i \mathbb{Z}}. \]
If $\mathbb{P}$ denotes the coproduct of $K^{\mathbb{Q}_p/\mathbb{Z}_p}$, then
\[ \mathbb{P}h^*(X) - 1 \otimes h^*(X) - h^*(X) \otimes 1 = \sum_{a,b \in \mathbb{Q}_p/\mathbb{Z}_p} [\sigma(a) + \sigma(b)]f_a \otimes f_b \in R^{\mathbb{Q}_p/\mathbb{Z}_p} \otimes R^{\mathbb{Q}_p/\mathbb{Z}_p}; \]
this tells us that $h^*(X)$ is an integral of second kind\(^5\) of $R^{\mathbb{Q}_p/\mathbb{Z}_p}$.

Moreover, the covector $\gamma$, and hence $\zeta$, can be recovered from $h^*(X)$. In fact by a direct computation one can check that $h^*(X) = \sum_{i=0}^{\infty} p^{-i} \tilde{y}^i$, where $\tilde{y}^{-i} \in R^{\mathbb{Q}_p/\mathbb{Z}_p}$ is a lifting of $y^{-i} \in K^{\mathbb{Q}_p/\mathbb{Z}_p}$.

Also the Dieudonné module of $\mu_{p^\infty}$ is a free $W(k)$-module of rank 1. Let $R[[Y]]$ be the affine algebra of $\mu_{p^\infty, R}$, where $Y$ is the canonical parameter and let $l(Y) \in \mathbb{Z}_{(p)}[[Y]]$ be the Artin–Hasse logarithm of $1 + Y$, i.e.
\[ \exp(-l(Y) - p^{-1}l(Y)p - p^{-2}l(Y)^2 - \ldots) = 1 + Y, \]
then, $M((\mu_{p^\infty})_{k}) = \delta W(k)$, where $\delta = (\ldots, l_0(Y_0), l_0(Y_0))$, and $l_0(Y_0)$ is the image of $l(Y)$ in the affine algebra of $\mu_{p^\infty, k}$.

\(^5\) We recall that given the algebra $A$ of a formal group over $R$, an integral of the second kind of $A$ is an element $f \in A \otimes_k K$ such that $df \in \Omega_R(A)$ and $\mathbb{P}f - f \otimes 1 - 1 \otimes f \in A \otimes_k A$, where $\mathbb{P}$ denotes the coproduct in $A$; we will denote by $I_2(A)$ the $R$-module of integrals of the second kind. Moreover if $\mathbb{P}f - f \otimes 1 - 1 \otimes f = 0$, $f$ is called an integral of the first kind.
Let us remark that \(-\log(1 + Y) = l(Y) + p^{-1}l(Y)p + p^{-2}l(Y)p^2 + \ldots\) is the integral of first kind of \((\mu_p^\infty)_R\) obtained by lifting \(\delta\).

Let \((\mathbb{Q}_p/\mathbb{Z}_p)_k^\vee = \lim_{\rightarrow} (\mathbb{Z}/p^n\mathbb{Z})_k^\vee\) be the Pontrjagin dual of \((\mathbb{Q}_p/\mathbb{Z}_p)_k\); then \(\mu_p^\infty,k\) is the Cartier dual of \((\mathbb{Q}_p/\mathbb{Z}_p)_k^\vee\); as a consequence there exist two perfect pairings of \(W(k)-\)modules:

\[
\langle -, - \rangle_C : \mathcal{M}(\mu_p^\infty,k) \times \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k^\vee) \to W(k) \quad \langle -, - \rangle_p : \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k) \times \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k^\vee) \to W(k).
\]

We will denote by

\[
id(1) : \mathcal{M}(\mu_p^\infty,k) \to \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k)
\]

the \(W(k)-\)isomorphism such that

\[
\langle m, n \rangle_C = (\id(1)(m), n)_p
\]

for every \(m \in \mathcal{M}(\mu_p^\infty,k)\) and \(n \in \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k^\vee)\). One can check that \(\id(1)(\delta) = \zeta\), so that

\[
F \circ \id(1) \circ V = \id(1).
\]

### 3.2. Monodromy and additive extensions

We want to define a \(W(k)\)-endomorphism of the Dieudonné module \(\mathcal{M}(\mathcal{M}(p)_k)\) depending on the monodromy \(N\). (See also \[7\] 5.2.2.) We proceed as follows:

\[
\begin{align*}
\mathcal{M}(Y^* \otimes \mu_p^\infty,k) \xrightarrow{\mathcal{M}(N_k)} \mathcal{M}(Y \otimes_{\mathbb{Z}} \mu_p^\infty,k) \xrightarrow{\id_Y(1)} \mathcal{M}(Y \otimes_{\mathbb{Z}} \mathbb{Q}_p/\mathbb{Z}_p) \\
\mathcal{M}(\mathcal{M}(p)_k) \xrightarrow{N} \mathcal{M}(\mathcal{M}(p)_k)
\end{align*}
\]

where the vertical map on the left comes from the obvious inclusion

\[
Y^* \otimes \mu_p^\infty,k = \lim_{\rightarrow} (p^n T_k) \to \lim_{\rightarrow} (p^n M_{\pi,k}^1)
\]

and the vertical map on the right is obtained from the projection

\[
\lim_{\rightarrow} (p^n M_{\pi,k}^1) \to Y \otimes_{\mathbb{Z}} (\mathbb{Q}_p/\mathbb{Z}_p).
\]

Recall now that both \(Y\) and \(Y^*\) are constant groups and hence

\[
\mathcal{M}(Y^* \otimes \mu_p^\infty,k) = Y^* \otimes \mathcal{M}(\mu_p^\infty,k), \quad \mathcal{M}(Y \otimes \mu_p^\infty,k) = Y^\vee \otimes_{\mathbb{Z}} \mathcal{M}(\mu_p^\infty,k).
\]

The morphism \(\mathcal{M}(N_k)\) is then

\[
\mathcal{M}(N_k) = \nu^\vee \otimes \id,
\]

where \(\nu^\vee : Y^* \to Y^\vee\) comes from the geometric monodromy \(\mu\) and is the transpose of \(\nu\) in \([7]\) (on special fibres). Using decompositions as in (20) we can define

\[
\id_Y(1) := \id \otimes \id(1) : Y^\vee \otimes \mathcal{M}(\mu_p^\infty,k) \to Y^\vee \otimes \mathcal{M}((\mathbb{Q}_p/\mathbb{Z}_p)_k)
\]
where id(1) is the canonical identification explained in \cite{Bertapelle}. The map $\text{id}_Y(1)$ is an isomorphism of $W(k)$-modules such that $F \circ \text{id}_Y(1) \circ V = \text{id}_Y(1)$ and the dotted arrow $\mathcal{N}^2 = 0$ and $F \mathcal{N} = \mathcal{N}$. 

We want now to describe how the composition $\text{id}_Y(1) \circ \mathcal{M}(N_k)$ works: Given an element $\chi \otimes \delta \in Y^* \otimes M(\mu_{p^n}, k)$, with $\delta$ the canonical generator of $M(\mu_{p^n}, k)$, 

\[(\text{id}_Y(1) \circ \mathcal{M}(N_k))(\chi \otimes \delta) = \text{id}_Y(1)(\nu^\vee(\chi) \otimes \delta) = \nu^\vee(\chi) \otimes \zeta.
\]

**Remark 5.** The construction above could also be done restricting to kernels of $p^n$-multiplication $p^n M$ and hence working with the monodromy homomorphism of level $p^n$,

\[\nu_{p^n}: Y \otimes \mathbb{Z}/p^n \mathbb{Z} \to Y^* \otimes \mu_{p^n}.
\]

This is what Kato does in \cite{Kato} 5.2.2. Hence the construction above is simply a way to summarize Kato’s construction for all $p^n$.

The element $\nu^\vee(\chi) \otimes \zeta \in Y^\vee \otimes M((\mathbb{Q}_p/\mathbb{Z}_p)_k) = M(Y \otimes (\mathbb{Q}_p/\mathbb{Z}_p)_k)$ can be described in different ways; we give here some examples without proofs:

i) If we interpret it as extension of $Y \otimes (\mathbb{Q}_p/\mathbb{Z}_p)_k$ by the additive group $G_{a,k}$, $\nu^\vee(\chi) \otimes \zeta$ is represented by the pull-back of the sequence $\zeta_{p^{\infty}}$ with respect to

\[(\nu^\vee(\chi), \text{id}): Y \otimes \mathbb{Z}/p \mathbb{Z} \to \mathbb{Q}/p \mathbb{Z}.
\]

ii) Given an extension of $\mathbb{Q}_p/\mathbb{Z}_p$ by $G_{a,k}$, the push-out with respect to the $m$-multiplication and the pull-back with respect to the $m$-multiplication provide isomorphic sequences. In a similar way one proves that the sequence $(\nu^\vee(\chi), \text{id})^\vee \zeta_{p^{\infty}}$ is also isomorphic to the push-out with respect to $(\nu^\vee(\chi), \text{id})$ of the sequence $Y \otimes \zeta_{p^{\infty}}$.

iii) Starting with the 1-motive $\pi: \mathbb{Z} \to G_{m,K}$, consider the sequence

\[0 \to G_{m,K} \to F_K \to \mathbb{Q}_p/\mathbb{Z}_p \to 0
\]

obtained first applying push-out $\mu_{p^n} \to G_{m,K}$ to the sequence $\eta(p^n, \pi)$ as in \cite{Candidera} and then passing to limit on $\mathbb{Z}/p^n \mathbb{Z}$. The sequence extends over $R$ (passing to Néron models) and then provides a sequence on component groups

\[0 \to \mathbb{Z} \to \phi_F \to \mathbb{Q}_p/\mathbb{Z}_p \to 0
\]

over $k$ that coincides with the opposite of the sequence $\zeta_{p^{\infty}}$ in \cite{Candidera}. The minus sign depends on Lemma \cite{Candidera}

More generally, given the 1-motive $u^2_{\pi,K}: Y_K \to T_K$ and a character $\chi \in Y^*$, the sequence $\nu^\vee(\chi) \otimes \zeta$ is obtained as follows: first consider the push-out $p^n T_K \to T_K$ in $\eta(p^n, u^2_{\pi,K})$ and then pass to limit on $Y_K/p^n Y_K$. At this point we have a sequence

\[0 \to T_K \to F_K \to Y_K \otimes \mathbb{Q}_p/\mathbb{Z}_p \to 0.
\]

Passing to Néron models and taking the induced sequence on component groups we get a sequence

\[0 \to Y^* \otimes \phi_F \to Y \otimes \mathbb{Q}_p/\mathbb{Z}_p \to 0.
\]
iv) We can also describe $\nu^\vee$ by taking the push-out with respect to $\chi$ whose valuation is the opposite of the additive factor set in (24), gives the extension obtained (25)

$\sum_i e_i \otimes a_i, \sum_i e_i \otimes b_i \mapsto \sum_i e_i \otimes [\sigma(a_i) + \sigma(b_i)]$

and hence a factor set

$\sum_i e_i \otimes a_i, \sum_i e_i \otimes b_i \mapsto \sum_i [\sigma(a_i) + \sigma(b_i)]\mu(e_i, \chi)$

of $(\nu^\vee(\chi), \id)_*(Y \otimes \zeta_p^{\text{add}})$. This factor set becomes trivial on generic fibres and a trivialization is given by

$h: Y_K \otimes \mathbb{Q}_p/\mathbb{Z}_p \to \mathbb{G}_{a,K}, \sum_i e_i \otimes a_i \mapsto \mu(e_i, \chi)\sigma(a_i)$.

If we read this trivialization in terms of formal groups and then pass to the affine algebras, $h$ corresponds to a $K$-homomorphism

$h^*: K[X] \to K^{\oplus_1 \mathbb{Q}_p/\mathbb{Z}_p e_i}, \ X \mapsto \sum_{a \in \oplus_1 \mathbb{Q}_p/\mathbb{Z}_p e_i} \sum_i \mu(e_i, \chi)\sigma(a_i)f_a$

where $f_a: \oplus_1 \mathbb{Q}_p/\mathbb{Z}_p e_i \to K$ is 1 in $a$ and 0 otherwise. Also in this case $h^*(X)$ is an integral of the second kind in $K^{\oplus_1 \mathbb{Q}_p/\mathbb{Z}_p e_i}$ that is sent to the class of $(\nu^\vee(\chi), \id)_*(Y \otimes \zeta_p^{\text{add}})$ via the map $I_2(Y \otimes \mathbb{Q}_p/\mathbb{Z}_p) \to \mathcal{M}(Y \otimes \mathbb{Q}_p/\mathbb{Z}_p)$.

Remark 6. The above constructions involve the part $u^2_{K, \pi}$ in Raynaud’s decomposition of the 1-motive $u_K$. In particular, the multiplicative factor set

$Y_K \otimes (\mathbb{Q}_p/\mathbb{Z}_p) \times Y_K \otimes (\mathbb{Q}_p/\mathbb{Z}_p) \to \mathbb{G}_{m,K}$

whose valuation is the opposite of the additive factor set in (24), gives the extension obtained by taking the push-out with respect to $\chi$ of the sequence (22). If we think of the valuation as a sort of logarithm killing elements in $R^+$, something similar in form, even if quite different in
nature, happens when working with 1-motives of the type \( u_{K,\pi}^1 : Y_K \to T_K \), and \( u_{K,\pi}^2 = 0 \): Also in the present situation we have a multiplicative factor set, it may be chosen as follows:

\[
\left( \sum_i e_i \otimes a_i, \sum_i e_i \otimes b_i \right) \mapsto \prod_i u(e_i, \chi)^{-[\sigma(a_i) + \sigma(b_i)]},
\]

where the \( u(e_i, \chi) \) are principal units in \( R \), so that the corresponding sequence extends to \( R \). Now, we can obtain from this an additive factor set by just taking the \( p \)-adic logarithm. As before, the additive factor set we get,

\[
\left( \sum_i e_i \otimes a_i, \sum_i e_i \otimes b_i \right) \mapsto \sum_i -[\sigma(a_i) + \sigma(b_i)] \log(u_i)
\]
is trivial on generic fibres and its trivialisation provides an integral of the second kind \( h(\chi) \in K^{Q_n/\mathbb{Z}_p} \) and the BT-group of \( u_{K,\pi}^1 \) is completely determined by the \( W(k) \)-module generated by the \( h(\chi) \), as \( \chi \) varies in the group of the characters of \( T_K \) (cf. \[5\], IV). Finally, let us observe that if one is just interested in computing the monodromy, then the use of the valuation is quite appropriate, but if one needs to consider the integrals of \( u_{K,\pi} = u_{K,\pi}^1 + u_{K,\pi}^2 \), i.e. one needs to integrate logarithmic differentials (in the style of \[2\]), one is forced to extend the \( p \)-adic logarithm defining \( \log \pi \) in a way allowing one to distinguish the integrals of \( u_{K,\pi}^1 \) from those \( u_{K,\pi}^2 \).

### 4. The finite logarithmic group that extends \( nM_K \)

Throughout this section we work with a strict \( K \)-1-motive \( u_K : \mathbb{Z} \to G_K \) where \( G_K \) is a semiabelian scheme with split torus part \( \mathbb{G}_m,K \) and with abelian quotient \( A_K \) having good reduction. Given the \( n \)-torsion \( nM_K \) of such a 1-motive, we know from Theorem \[2\] that it extends to a finite logarithmic group over \( R \), \( nM^\log \), but we still know little concerning the scheme \( nM \) underlying \( nM^\log \). In this section we are going to describe the logarithmic group scheme \( nM^\log \) for any \( n \) and precisely we will show that \( nM^\log \) is the valuative space associated to \( (\text{Spec}(nA), \mathcal{M}_A) \) where \( nA \) is an algebra over \( R \), constructed in a somewhat canonical way, and \( \mathcal{M}_A \) is a logarithmic structure on \( \text{Spec}(nA) \) such that the structure morphism over \( R \) induces a morphism of log schemes \( \text{Spec}(nA), \mathcal{M}_A) \to \overline{T} \).

We have seen that \( nM_K \) is an extension of \( Y_K/nY_K \) by \( nG_K \), hence a \( nG_K \)-torsor over \( Y_K/nY_K \). If \( nG_K = \mathbb{A}^d \), it is easy to describe the algebra of \( nM_K \); cfr. \[13\], \[1\]. For example for the Tate curve \( \pi : \mathbb{Z} \to \mathbb{G}_m,K \) we denoted \( nM_K \) by

\[
\tau E_K = \text{Spec} \left( \mathbb{K}^{\mathbb{Z}/n\mathbb{Z}}[x]/(x^n - b_{\pi,n}) \right)
\]

with \( b_{\pi,n} = \sum_{j=0}^{n-1} \pi^j v_j \), where \( \{v_0, \ldots, v_{n-1}\} \) is the canonical basis of \( \mathbb{K}^{\mathbb{Z}/n\mathbb{Z}} \). See also \[14\].

For the general case, we read from \[13\] that \( nM_K \) is indeed a \( \mu^d \)-torsor over the finite \( K \)-group scheme \( nM^A_K \). Recalling that \( \text{Pic}(nM^A_K) = 0 \), \( nM_K \) can easily be described via \[13\] III §4.

**Lemma 7.** Let \( B_K \) be the algebra of \( nM^A_K \). Then

\[
\tau M_K = \text{Spec} (B_K[T_1, \ldots, T_d]/(T_1^n - b_1, \ldots, T_d^n - b_d))
\]

for suitable \( b_i \in B_K^*, i = 1, \ldots, d \).
4. Monodromy of logarithmic Barsotti-Tate groups attached to 1-motives

We need now to describe how the \( b_i \) above depend on Raynaud’s decomposition of the 1-motive \( u_K \).

### 4.1. The 1-motive \( \pi^{-1} \)

Before proceeding with the description of \( nM_K \) we need to know what happens when working with the 1-motive \( \pi^{-1} \): \( \mathbb{Z} \to \mathbb{G}_{m,K}, 1 \mapsto \pi^{-1} \). Its \( n \)-torsion group scheme is

\[
(28) \quad nE_{\mathbb{Z} K}^{\pi^{-1}} = \text{Spec} \left( \frac{K^{\mathbb{Z}/n\mathbb{Z}}[x]}{(x^n - \sum_{i=0}^{n-1} \pi^{-i}v_i)} \right)
\]

with \( \{v_0, \ldots, v_{n-1}\} \) the canonical base of \( K^{\mathbb{Z}/n\mathbb{Z}} \) over \( K \). It is clear that we can not extend its algebra over \( R \) via the equation \( x^n - \sum_{i=0}^{n-1} \pi^{-i}v_i \). However, \( nE_{\mathbb{Z} K}^{\pi^{-1}} \) is isomorphic to the group scheme obtained from (15) by push-out with respect to \( -1 \) or by pull-back with respect to \( -1 \). Hence it is also

\[
(29) \quad nE_{\mathbb{Z} K}^{\pi^{-1}} \cong \text{Spec} \left( \frac{K^{\mathbb{Z}/n\mathbb{Z}}[y]}{(y^n - v_0 - \sum_{i=1}^{n-1} \pi^{-n-i}v_i)} \right)
\]

because \( -1: \mathbb{Z} \to \mathbb{Z} \) sends \( v_0 \mapsto v_0 \), \( v_i \mapsto v_{n-i} \) for \( i > 0 \). Moreover this scheme extends over \( R \) to

\[
(30) \quad nE_{\mathbb{Z} K}^{\pi^{-1}} = \text{Spec} \left( \frac{R^{\mathbb{Z}/n\mathbb{Z}}[y]}{(y^n - v_0 - \sum_{i=1}^{n-1} \pi^{-n-i}v_i)} \right)
\]

We can endow \( nE_{\mathbb{Z} K}^{\pi^{-1}} \) with the logarithmic structure coming from the special fibre and it becomes a logarithmic group scheme over \( R \). Denote by \( n(E_{\mathbb{Z} K}^{\pi^{-1}}) \) its valuative logarithmic space; this lies in the middle of \( -\theta_n \pi \) for \( \theta_n \) as in (15).

Another decomposition of a 1-motive that will be useful later is the following:

**Lemma 8.** Let \( u_K \) be a 1-motive as in Theorem 4. Suppose furthermore that \( Y_K \) is split and also the torus part \( T_K \) of \( G_K \) is split. Once fixed a uniformizing parameter \( \pi \in R \), a basis \( (e_j)_j \) of \( Y_K \cong \mathbb{Z}^r \) and a basis \( (e^*_i)_i \) of \( Y^*_K \) there are decompositions

\[
u_K = u_K^1 + u_K^2 = u_K^1 + v_K^+ + v_K^-
\]

where the first one is the decomposition in Theorem 4. The second decomposition is uniquely determined by the following conditions:

1. \( u_K^\pm: Y_K \to G_K \) factor through the torus part.
2. If \( \mu^+ \) (resp. \( \mu^- \)) denotes the geometric monodromy of \( u_K^+ \) (resp. of \( u_K^- \)), then one has \( \mu^+(e_j, e^*_i) \geq 0 \) (resp. \( \mu(e_j, e^*_i) \leq 0 \)).
3. \( u_K^2 = u_K^1 + u_K^- \) and \( \mu = \mu^+ + \mu^- \).
Proof. We are reduced to working with $u^2_{K,\pi}$. We define

$$\mu^+ : Y_K \otimes Y^*_K \rightarrow \mathbb{Z}, \quad (e_j, e^*_i) \rightarrow \begin{cases} \mu(e_j, e^*_i) \text{ if this is positive} \\ 0 \text{ otherwise} \end{cases}$$

Similar for $\mu^-$. Moreover $u^\pm_{K,\pi}$ is defined as done for $u^2_{K,\pi}$ in \ref{4.1} with $\mu^\pm$ in place of $\mu$. \hfill \Box

Remark 7. Recall the decomposition in Lemma \ref{4.1} and the factorization $u^2_{K,\pi} = (\nu \otimes \id)\pi_Y$. Let us construct $\nu^\pm : Y_K \rightarrow (Y^*_K)^\nu$ from the geometric monodromy $\mu^\pm$ as in \ref{4.1}. Then we have factorizations $u^\pm_{K,\pi} = (\nu^\pm \otimes \id)\pi_Y$ (resp. $u^\pm_{K,\pi} = (\nu^- \otimes \id)\pi_Y^{-1}$) with

$$\pi_Y^{-1} : Y_K \rightarrow Y_K \otimes_{\mathbb{Z}} \mathbb{G}_{m,K}, \quad y \mapsto y \otimes \pi^{-1}.$$ 

4.2. A general result on short exact sequences

Looking at the diagram \ref{4.2} where $\pi T_K = \mu^i_1$ we realize that we should move our attention from the horizontal sequence in the middle $\eta(u, u_K)$ to the vertical sequence in the middle, because, as we have already observed $\mu_n$-torsors can easily be described. Moreover we need to know how such a "vertical sequence" depends on the analogous sequences for $u^1_{\pi,K}$ and $u^2_{\pi,K}$. For this we need a general result.

Let $\tilde{\psi} : 0 \rightarrow I \rightarrow L \rightarrow P \rightarrow 0$ be an exact sequence of group schemes over a base scheme $S$.

Let $N$ be another group scheme over $S$ and consider two extensions $\eta^i : 0 \rightarrow L \rightarrow \tilde{M}^i \rightarrow N \rightarrow 0$, $i = 1, 2$. Let $\eta : 0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ be a sequence isomorphic to the Baer sum $\eta^1 + \eta^2$. Consider then the following diagrams

\[ \begin{array}{cccccccc}
\eta^i : & 0 & \rightarrow & I & \rightarrow & L & \rightarrow & M^i & \rightarrow & N & \rightarrow & 0 \\
\eta^i : & 0 & \rightarrow & I & \rightarrow & L & \rightarrow & M^i & \rightarrow & N & \rightarrow & 0 \\
\end{array} \]

where the vertical sequence on the left is $\tilde{\psi}$ and the upper horizontal sequence is $\eta^i$ for $i = 1, 2$ (resp. $\eta$). Call $\psi^i$ for $i = 1, 2$ (resp. $\psi$) the vertical sequence in the middle. Suppose now that there is a sequence

$$\tilde{\eta}^2 : 0 \rightarrow I \rightarrow \tilde{M}^2 \rightarrow N \rightarrow 0$$

such that $\eta^2 = w \tilde{\eta}^2$. Summarizing we have

$$\eta \cong \eta^1 + w \tilde{\eta}^2.$$ 

We are going to see that a similar relation holds also for the vertical sequences $\psi, \psi^1$.

Now $k_*w_* \tilde{\eta}^2$ is isomorphic to the trivial extension and we choose a section $\sigma$ of $f^2$. Moreover $k_*\eta \cong k_*\eta^1$ and there is then an isomorphism $\psi : Q \rightarrow Q^1$ depending on $\sigma$. It is also not difficult to check that

$$\psi \cong (\sigma)^* \psi^1 + (\sigma f)^* \psi^2$$

(31)
Consider also the following push-out diagram

\[ \begin{array}{c}
\eta^2: & 0 \to I \to M^2 \to \tilde{h}^2 \to N \to 0 \\
w_* \eta^2 = \eta^2: & 0 \to L \to M^2 \to h^2 \to N \to 0 \\
k_* \eta^2: & 0 \to P \to Q^2 \to f^2 \to N \to 0
\end{array} \]

where lower sequence is isomorphic to the trivial one. We denoted by \( \psi^2 \) the exact sequence involving \( g^2 \) and \( \tau^2 \). There exists then a canonical homomorphism \( \sigma^c \) such that

\[ (\sigma^c)^* \psi^2 \cong \tilde{\eta}^2 \]

Taking now \( \sigma = \sigma^c \) in (31) and setting \( \iota^*: = \iota^{c*} \) we get that

\[ (32) \quad \psi \cong \iota^* \psi^1 + f^* \tilde{\eta}^2 \cdot \]

4.3. \( nM_K \) as torsor under \( \mu^d_n \)

Let \( u_K \) be a 1-motive as in Theorem 1. We have then a decomposition \( u_K = u_{K,\pi}^1 + u_{K,\pi}^2 \) and an isomorphism of sequences \( \eta(n, u_K) \cong \eta(n, u_{K,\pi}^1) + \eta(n, u_{K,\pi}^2) \) for \( \eta(n, -) \) the sequence introduced in 4.

The \( n \)-torsion \( M_K \) of \( u_K \) lies in the middle of \( \eta(n, u_K) \) and we have already seen what it looks like in Lemma 4. Moreover \( \eta(n, u_{K,\pi}^2) = w_* \eta(n, \tilde{u}_{K,\pi}^2) \), where the 1-motive \( \tilde{u}_{K,\pi}^2: Y_K \to T_K \) is obtained from \( u_{K,\pi}^2 \) by forgetting the inclusion \( T_K \to G_K \) and \( w \) is this inclusion restricted to kernels of \( n \)-multiplication. Hence we are in the situation of the subsection 4.2.

Considering diagram (6) for \( \eta(n, u_{K,\pi}^1) \) in place of \( \eta(n, u_{K,\pi}) \) we get

\[ (33) \quad \eta(n, u_{K,\pi}^1): 0 \to nG_K \to nM_{K}^1 \to h^1 \to Y_K/nY_K \to 0 \]

Let \( \psi(n, u_{K,\pi}^1) \) be the vertical sequence in the middle of this diagram and \( \psi(n, u_{K,\pi}) \) the corresponding vertical sequence in the middle of (6). By (32) we have

\[ (34) \quad \psi(n, u_K) \cong \iota^* \psi(n, u_{K,\pi}^1) + f^* \eta(n, \tilde{u}_{K,\pi}^2) \]
for \( \iota \) the isomorphism \( n M^A_K \to Q^1_K \) constructed as in \([12]\). By abuse of notations, we denote by \( n M^1_K \) also the group scheme in the middle of \( \iota^* \psi(n, u_{K, \pi}) \); indeed it is isomorphic to the one in the middle of \( \eta(n, u_{K, \pi}) \). The scheme \( n M^1_K \) is a \( \mu_n^d \)-torsor over \( n M^A_K \) and hence

\[
n M^1_K \cong \text{Spec} \left( B_K[T_1, \cdots, T_d]/(T_1^n - b_1^{(1)}, \cdots, T_d^n - b_d^{(1)}) \right).
\]

On the other hand, call \( n \tilde{M}^2_K \) the group in the middle of \( \eta(n, \tilde{u}_{K, \pi}^2) \). It is a \( \mu_n^d \)-torsor over \( \mathbb{Z}^r/n\mathbb{Z}^r \) and hence it has the form

\[
n \tilde{M}^2_K \cong \text{Spec} \left( K^{\mathbb{Z}^r/n\mathbb{Z}^r}[T_1, \cdots, T_d]/(T_1^n - b_1^{(2)}, \cdots, T_d^n - b_d^{(2)}) \right).
\]

Hence the group in the middle of \( f^* \eta(n, \tilde{u}_{K, \pi}^2) \) will be

\[
\text{Spec} \left( B_K[T_1, \cdots, T_d]/(T_1^n - b_1^{(2)}, \cdots, T_d^n - b_d^{(2)}) \right).
\]

Recall now that \( \tilde{u}_{K, \pi}^2 = u_{K, \pi}^2 + u_{K, \pi}^- \) by Lemma \([3]\) and hence \( \eta(n, u_{K, \pi}^2) \cong \eta(n, u_{K, \pi}^-) + \eta(n, u_{K, \pi}) \).

Let

\[
\text{Spec} \left( K^{\mathbb{Z}^r/n\mathbb{Z}^r}[T_1, \cdots, T_d]/(T_1^n - b_1^+, \cdots, T_d^n - b_d^+) \right)
\]

be the group scheme in the middle of \( \eta(n, u_{K, \pi}^+) \) and analogously for \( u_{K, \pi}^- \) with elements \( b_i^- \in K^{\mathbb{Z}^r/n\mathbb{Z}^r} \) in place of \( b_i^+ \). Using the sequence

\[
0 \to \mu_n^d(X) \to \Gamma(X, \mathcal{O}_X)^{d*} \to \Gamma(X, \mathcal{O}_X)^{d*} \to H(X, \mu_n^d) \to 0
\]

we may assume that \( b_i^{(2)} = b_i^+ b_i^- \) and

\[
b_i = b_i^{(1)} b_i^+ b_i^- \quad \text{for all} \quad 1 \leq i \leq d.
\]

Recall now that the vertical sequence on the left in \([8]\) or \([9]\) extends over \( R \) because \( G_K \) has good reduction and that also \( n M^A_K \) extends to a finite group scheme over \( R \), say \( n M^A = \text{Spec}(B) \), because the \( K \)-motive

\[
p^A_K: \mathbb{Z}^r \to G_K \to A_K
\]

has good reduction. Finally also \( \eta(n, u_{K, \pi}) \) extends over \( R \) and hence the same is true for the vertical sequence \( \psi(n, u_{K, \pi}) \) and so we may assume \( b_i^{(1)} \in B^* \). This implies that if we want to extend \( n M_K \) over \( R \) we have to understand better \( n M^2_K \) and hence \( b_i^{(2)} = b_i^+ b_i^- \). Recall the description of \( u_{K, \pi}^+ \) in \([10]\) where now \( Y_K = \mathbb{Z}^r \) and \( T_K = G^a_{m,K} \). It is an easy exercise to check that

\[
b_i^+ = (b_{\pi,n}) \sum_{j=1}^{r} \mu^+(v_j, e_j^+) \quad \text{with} \quad b_{\pi,n} : = \sum_{j=0}^{n-1} \pi^j v_j \in R^{Z^n/nZ^n},
\]

with \( v_0, \ldots, v_{n-1} \) the standard basis of \( K^{\mathbb{Z}/n\mathbb{Z}} \) (resp. \( R^{Z^n/nZ^n} \)), \( e_1, \ldots, e_r \) the usual basis of \( \mathbb{Z}^r \) and \( e_i^+ \) the character in \( Y_K^* \) such that \( e_i^+(T_k) = \delta_{ik} \cdot \mu^+ \) the geometric monodromy of \( u_{K, \pi}^+ \). Moreover \( \mu^+(e_j, e_i^+) \geq 0 \) by definition of \( u_{K, \pi}^+ \); hence \( b_i^+ \in B \) for all \( i \). In a similar way

\[
b_i^- = (b_{\pi-1,n}) \sum_{j=1}^{r} \mu^-(v_j, e_j^+) \quad \text{with} \quad b_{\pi-1,n} : = v_0 + \sum_{i=1}^{n-1} \pi^{n-i} v_i \in R^{Z^n/nZ^n}.
\]
Hence also \( b_i \in B \) for all \( i \) because \( \mu^-(e_j, e_i) \leq 0 \) by definition of \( u_{K,n} \). Summarizing, \( b_i = b_i^{(1)} + b_i^{(2)} = b_i^{+} + b_i^{-} \in B \) for all \( i \). Hence \( n M_K \) extends to a finite scheme over \( \text{Spec}(B) \)

\[(36) \quad n M = \text{Spec}(B[T_1, \cdots , T_d]/(T_1^n - b_1, \cdots , T_d^n - b_d)).\]

The following lemma says that \( n M \) is indeed a “nice” model.

**Lemma 9.** Let notations be as above and endow \( n M^A = \text{Spec}(B) \) with the inverse image log structure of the base \( T \). Let \((n M, M_{n M})\) be the scheme \( [\frac{B}{B}] \) with the logarithmic structure induced by the special fibre. Then the canonical morphism \( n M_K \rightarrow n M^A_K \) extends to a unique morphism of logarithmic groups over \( R \). Moreover the following universal property holds: For any fine saturated logarithmic scheme \((S, M_S)\) over \((n M^A, M_{n M}^A)\) there is a bijection between the scheme theoretic morphisms \( S_K \rightarrow n M_K \) over \( n M^A_K \) and the logarithmic morphisms \((S, M_S) \rightarrow (n M, M_{n M})\) over \((n M^A, M_{n M}^A)\).

**Proof.** We may assume \( S = \text{Spec}(C) \) affine. Any \( n M^A_K \)-morphism \( S_K \rightarrow n M_K \) is described as a homomorphism of \( B_K \)-algebras \( \varphi_K : B_K[T_1, \cdots , T_d]/(T_1^n - b_1) \rightarrow C_K \). The only problem for the extension is to prove that the images of all \( T_i \) lie in \( C \) and more precisely in \( \Gamma(S, M_S) \). However \( b_i = b_i^{(1)} + b_i^{(2)} \) with \( b_i^{(1)} \in B^+ \) and \( b_i^{(2)} \in \Gamma(Y, M_Y) \) for any logarithmic space over the group \( \mathbb{Z}/n\mathbb{Z} \) endowed with the inverse image log structure because of the description of \( b_i^{(2)} \) in terms of \( b_{\pi,n} \) and \( b_{\pi - 1,n} \). Moreover \( \varphi_K(T_i^n) = \varphi_K(b_i) \in \Gamma(S, M_S) \). It is now sufficient to recall that \( S \) is saturated to conclude that also \( \varphi_K(T_i) = b_i \in \Gamma(S, M_S) \). \( \square \)

**Proposition 1.** Let notations be as above. The finite group scheme \( n M_K \) over \( n M^A_K \) extends (up to isomorphisms) to a finite logarithmic group \( n M^K \) that is the valuative logarithmic space associated to a logarithmic scheme whose underlying scheme is

\[(37) \quad n M = \text{Spec}(B[T_1, \cdots , T_d]/(T_1^n - b_1, \cdots , T_d^n - b_d)).\]

Moreover the diagram \( \square \) extends to a diagram of finite logarithmic groups with \( n M^K \) in the middle.

**Proof.** It remains only to prove that \( n M \) with the logarithmic structure induced by the special fibre induces a group functor on the category of fine saturated logarithmic schemes over \( R \), i.e. it is in \( T^K_n \). However this is immediate consequence of the previous lemma.

Also the assertion on the diagram follows applying the previous lemma. \( \square \)

Observe that we had already proved in Theorem \( \square \) that \( n M_K \) extends to a logarithmic group over \( T \), however, in the hypothesis of this section, it is possible to describe it in terms of algebras and not only as a “sum” of two extensions.
